Poster Title: Effectiveness of pharmacist-led motivational interviewing interventions: A systematic review and meta-analysis

Primary Author: Caroline Liang, University of Connecticut, Connecticut; **Email:** caroline.liang@uconn.edu

Additional Author (s):
Rachel Eyler

Purpose: Motivational interviewing (MI), a collaborative communication style for strengthening motivation and commitment to change, can facilitate positive health behavior change and address medication nonadherence. Pharmacists are key health care providers who are in a position to counsel nonadherent patients using MI. However, the effectiveness of MI is uncertain and no systematic reviews currently exist that evaluate the efficacy of pharmacist-led MI interventions. This systematic literature review and meta-analysis explore the effectiveness of pharmacist-led MI interventions in improving health behaviors in patients.

Methods: The databases PubMed and Ovid MEDLINE were searched to identify studies that involved pharmacists providing MI as an intervention in any disease state. One reviewer assessed the relevance of citations based on the inclusion and exclusion criteria. Studies were included if they were in English and included an intervention that involved pharmacists providing MI. Studies were excluded if they were not clinical trials; systematic reviews, case reports, and other nonclinical trials were not reviewed. Details of the included studies were collected by one reviewer using a standardized data extraction form developed for the review. Data collected included study location and setting; study publication date; disease state studied; specifics about the intervention, including format, length, and any pharmacist training involved; participant demographics and count; outcome measures; and results. When multiple studies examined a common endpoint, meta-analyses were conducted using a fixed-effects model.

Results: Fourteen studies were identified, eight of which were randomized controlled trials. MI did not significantly improve outcomes in the following disease states compared to control: immunization rates, methadone use for substance abuse, alcohol abuse, rheumatoid arthritis,

chronic obstructive pulmonary disease, pneumonia, and recent stroke or transient ischemic attack. MI did significantly improve outcomes in hypercholesterolemia. In diabetic patients, MI resulted in a higher proportion of adherent patients compared to control, although the statistical significance of this difference was not assessed. MI also improved readiness to quit in a smoking cessation intervention and increased adherence in patients with human immunodeficiency virus or acquired immunodeficiency syndrome, although there was no independent control group for either study. Three studies assessed hypertension, with one having significant improvement of outcomes with MI compared to control and the other two had no significant difference. Meta-analyses found pooled risk differences for the impact of MI on adherence was -0.042 (95 percent CI, -0.073 to -0.011), and the impact of MI on blood pressure was -2.2 mmHg (95 percent CI, -4.0 to -1.4).

Conclusion: The evidence in this review was insufficient to determine the effectiveness of pharmacist-led MI interventions. The majority of the disease states discussed were represented by only one study, and many of the studies included were small, exploratory in nature, or lacked an independent control group, which severely limited analysis. Meta-analyses did find a benefit on medication adherence when pharmacists provided MI to patients. Pharmacists were able to help patients modestly lower blood pressure was well. Further large randomized controlled trials are needed to fully elucidate the role of pharmacist-led motivational interviewing.

Poster Title: Evaluation of a continuing education certificate program designed to educate pharmacists on colorectal cancer risks and screening

Primary Author: Hannah Buckler, University of Connecticut, Connecticut; **Email:** hannah.buckler@uconn.edu

Additional Author (s):
Lisa Holle

Purpose: Colorectal cancer (CRC) is the third most commonly diagnosed type of cancer and third leading cause of death due to cancer. CRC screening has been shown to be highly effective at identifying cancer yet according to the National Health Interview Survey in 2010, only 59% of people for whom screening is recommended are tested. This project was designed to evaluate the use of a continuing education program intended to educate pharmacists on CRC so that they may in turn educate patients on the risks associated with disease and the benefits of screening.

Methods: An Accreditation Council for Pharmacy Education (ACPE)-accredited continuing education certificate program was designed as part of a larger study developed to evaluate the feasibility of pharmacists as a means to educate patients on various topics including risks of CRC and benefits of cancer screening. The program had two portions: a 10-hour didactic component and a 5-hour practice component. The didactic component was designed to cover the basics of cancer screening and CRC risks in addition to various health disparities in CRC and communication skills for health behavior change. The program also included lectures on collaborative practice agreements and screening statistics. The practice component included a workshop which reviewed the material from the online lectures, discussed any questions the participants had about the material, and included a role-playing element which encompassed a CRC risk discussion with a patient, motivational interviewing, and brainstorming potential barriers to CRC screening. To assess the knowledge of the pharmacists who participated in this program, a pre-test was required before listening to the online lectures in each module as well as a post-test after completion. These tests were scored out of 100 and feedback from the practice component of the module was also collected. The participating pharmacists evaluated

each module after completion using a Likert scale and several open-ended questions asking for specific feedback. Descriptive statistics were used to analyze the data.

Results: Ten pharmacists completed the program, each pharmacist completed 9 pre-tests and 9 post-tests corresponding to the 9 modules. Therefore, a total of 90 pre-test scores and 90 post-test scores were evaluated. The median pre-test score was 50% (range, 13-100%) with one 100% achieved. The median post-test score was 84% (range, 38-100%) with 24 100% scores attained. Setting a passing threshold at 75% or above, before completion of the modules 15 passing scores (16%) were reported compared with 66 passing scores (73%) after completion of the modules. Increases in score on the pre- vs. post-test ranged from 10% to 80% after pharmacists completed the program. Evaluation of individual questions scores showed 15 out of 75 total post-test questions (20%) had an increased score of 50% or greater. Eighty-percent or more of pharmacists answered strongly agree or agree to evaluation questions asking if the modules were presented in a fair and unbiased manner, met learning objectives, and were organized in presentation. Evaluation comments from the pharmacist participants revealed the modules were informative and well taught (e.g., "[presentation] was enlightening as to the role pharmacists can play in patient care" and "very well presented and added to my knowledge base").

Conclusion: This certificate program was effective at educating pharmacists on CRC and cancer screening as evidenced by increased post-test scores compared with pre-test scores. Additionally, pre-and post-test scores as well as evaluations were able to successfully identify strengths and weaknesses of the certificate program. The information gathered from this descriptive report can be used to help update future CRC education programs for pharmacists, which may be useful for pharmacists who wish to gain a better understanding of cancer screening and prevention and apply this to their practice.

Poster Title: Valganciclovir dose and cytomegalovirus infection increase the risk of neutropenia in patients post-renal transplant

Primary Author: Vincent Do, University of Connecticut, Connecticut; **Email:** vincent.do@uconn.edu

Additional Author (s):
Gloriana Colon
Elizabeth Cohen
David Reardon

Purpose: The risk factors for neutropenia post-renal transplant are not well characterized. Several factors have been implicated in reducing neutrophil counts including recipient age greater or equal to 65, post-transplant viral infections, the type of induction agents used, and the use of valganciclovir (VAL) and mycophenolate mofetil (MMF). The objective of this study was to determine risk factors associated with the development of neutropenia in renal transplant patients.

Methods: A single center retrospective chart review was performed during the period of March 2014 to February 2016 and included patients age 18 years and older who received a kidney transplant and were followed up for six months. Patients were excluded from this analysis if they received a multi-organ transplant, had an incomplete medical record, or were lost to follow up. The primary outcome was to evaluate the correlation of the following factors with the development of neutropenia: recipient age, gender, type of induction agent used, average MMF dose, VAL dose, and the presence of infection by cytomegalovirus (CMV) and/or BK polyomavirus prior to or at the same time as neutropenia. The type of induction agents evaluated were alemtuzumab, rabbit anti-thymocyte globulin, and basiliximab. Neutropenia was defined as an absolute neutrophil count of less than or equal to 500 cells/mm3. Secondary outcomes include evaluating the frequency of dose adjusting MMF and/or VAL and the use of filgrastim. All categorical data was evaluated using a two-tailed Fisher's exact test. All continuous data was evaluated using an unpaired t test. A p value of less than 0.05 was required to be considered statistically significant.

Results: A total of 183 patients were screened where five patients were excluded due to less than six months of follow up. Of the 178 patients included in this analysis, 19 were in the neutropenia group and 159 were in the non-neutropenic group. There were no differences seen in the following risk factors: mean age, gender, induction agent used, MMF dose, and BK polyomavirus. The following risk factors were significant: CMV infection (7 patients versus 7 patients, p equals 0.0001) and VAL dose (615.8 milligrams versus 355.4 milligrams, p equals 0.0004). In the neutropenic group, 94.7 percent of patients received filgrastim. Dose adjustments of VAL and/or MMF occurred in 21.1 percent of patients prior to filgrastim, 57.9 percent had dose adjustments with filgrastim, 15.8 percent received only filgrastim, and 5.3 percent only had dose adjustments. In the non-neutropenic group, 12 patients received treatment to increase neutrophil counts. Of these, 91.7 percent received filgrastim where 8.3 percent had a dose adjustment prior to filgrastim, 50 percent had dose adjustments with filgrastim, 33.3 percent received only filgrastim, and 8.3 percent only had dose adjustments.

Conclusion: Patients post-renal transplant who developed neutropenia were more likely to have a CMV infection and be exposed to higher doses of VAL. Further studies are needed to evaluate this correlation.

Poster Title: Antimicrobial stewardship restricts the inappropriate use of ertapenem

Primary Author: Angela Giarratano, University of Connecticut, Connecticut; **Email:** angela.giarratano@uconn.edu

Additional Author (s):
Mireya Wessolossky

Purpose: The appropriate use of antimicrobial agents is essential to prevent the development of multi-drug resistant organisms and to reduce overall cost of care. The Joint Commission recently proclaimed that antimicrobial stewardship is a new medication management standard for hospitals. Carbapenem antibiotics have activity against many gram-negative organisms including those that produce extended spectrum beta-lactamases. These antibiotics are rarely indicated as first-line therapy for prophylaxis or treatment of infection. This project was developed to discover inappropriate use of broad-spectrum carbapenems in a non-profit hospital.

Methods: This study investigated the frequency of inappropriate antibiotic use of ertapenem. The study was conducted in Day Kimball Hospital in Putnam, Connecticut. The investigators included a medical doctor with advanced training in infectious disease and two pharmacy students. Patients were included in the investigation if he/she received at least one dose of ertapenem over the 30-day time period (07/15/16-08/15/16). There were no exclusion criteria. The information was collected using the electronic medical record of the hospital. The data gathered included dosage, duration of therapy, microbiology results if applicable, and indication for therapy for each patient. The medical doctor determined if usage was appropriate with the help of the pharmacy students by referencing the Infectious Diseases Society of America (ISDA) guidelines.

Results: Pharmacy students recorded that twenty-seven patients were administered ertapenem intravenously over the thirty-day-period. The medical doctor and two pharmacy students reviewed each patient case together and determined the use of ertapenem was appropriate in four out of the twenty-seven cases (14.8 percent). Over the thirty-day-period ertapenem was administered for prophylaxis of shoulder surgery (7), prophylaxis of knee

surgery (2), cellulitis with negative microbiology cultures (2), gastrointestinal bleeding (1), appendectomy (2), laparoscopic cholecystectomy (2), exploratory laparotomy (1), peri-rectal abscess draining (1), abscess (2), post-surgical pain and tenderness (1), perforated bowel (1), cholecystitis (1), urinary tract infection (2), and colon resection (2). The appropriate cases included treatment of the complicated urinary tract infections and the colon resection.

Conclusion: Antimicrobial stewardship is an essential implementation in healthcare systems of all sizes. Utilizing antimicrobial stewardship in this small non-profit hospital may lead to decreases in inappropriate antibiotic usage, cost savings, formulary changes, and education of healthcare professionals. Collaboration between pharmacists and medical doctors in antimicrobial stewardship may lead to better health outcomes and lower resistance rates in the community.

Poster Title: Evaluation of an anti-activated factor ten pilot protocol versus a partial thromboplastin time protocol in patients receiving continuous unfractionated heparin infusions

Primary Author: Thomas Walczyk, University of Connecticut, Connecticut; **Email:** thomas.walczyk@uconn.edu

Additional Author (s):
Laura Hobbs
Spencer Martin
Jyoti Chhabra
Antonio Fernandez

Purpose: Unfractionated heparin (UFH) infusions play a major role in anticoagulation therapy for thrombotic disorders in the hospital setting. Because of its low therapeutic index, it requires monitoring usually via a partial thromboplastin time test (PTT). Anti-activated factor X (anti-Xa) monitoring detects the therapeutic effect of the drug faster and more precisely than conventional PTT, thus reducing dose adjustments and frequency of monitoring. The purpose of this study was to determine whether dosing UFH infusions using an anti-Xa protocol was as safe and effective compared to the previous dosing strategies that utilized a PTT protocol at our institution.

Methods: The institutional review board approved this single-center, prospective, observational study using the anti-Xa protocol and its comparison to a retrospective PTT cohort. Patients who were less than 18 years old or who did not receive a continuous UFH infusion for at least 24 hours were excluded in both cohorts. The prospective cohort included patients who were admitted to specific cardiology pilot units, and received UFH infusions following the new anti-Xa protocol. Patients in the prospective cohort were excluded if they received UFH therapy based on the PTT protocol anytime during the same admission. The retrospective cohort was selected randomly from patients who received UFH infusions at our institution from January 1, 2014 to March 15, 2015 using the PTT protocol. A convenience sample of 100 patients was chosen: 50 patients in each cohort. Data on demographics, diagnosis, baseline comorbidities, concurrent medications, laboratory parameters, and clinical outcomes were collected. Continuous variables are expressed as mean plus/minus standard deviation and were

compared using the Student's t-test. Categorical variables are listed as percentages and compared using the Chi-squared test; however in instances where less than five data points were available, the Fischer's Exact test was used. A P value less than 0.05 was considered statistically significant.

Results: Four patients in the anti-Xa cohort were transferred from the predetermined pilot units to another floor, where they received UFH therapy based on the PTT protocol and were therefore excluded from our analysis. This resulted in 46 patients in the anti-Xa group and 50 patients in the PTT group. The patients in the anti-Xa group were older (69.96 plus/minus 11.60 vs. 63.38 plus/minus 15.10, p = 0.019), and had more chronic kidney disease (39.1 percent vs. 20 percent, p = 0.046) than the patients in the PTT group. There were no differences in the incidence of bleeding (21.8 percent vs. 18 percent, p = 0.798), or thrombosis development (4.3 percent vs. 2 percent, p = 0.606) while receiving UFH. No other significant differences were noted between the two groups.

Conclusion: Anti-Xa activity measurement has emerged as a potential new standard of care for inpatient monitoring of continuous UFH infusions. Our study demonstrated no significant differences in the rates of bleeding or thrombosis between the anti-Xa and the PTT-monitored groups, and that the new anti-Xa protocol is just as safe and effective as the previously utilized PTT protocol. These data support the use of anti-Xa measurements as a safe and effective way to monitor UFH administration.

Session-Board Number: 2-006

Poster Title: Characterization of alvimopan prescribing at a tertiary academic medical center

Primary Author: Katelyn Boel, University of Connecticut, Connecticut; **Email:** katelyn.boel@uconn.edu

Additional Author (s):
Lauren Vieira

Purpose: Alvimopan is a peripherally acting mu-opioid antagonist used to accelerate recovery time and prevent post-operative ileus (POI) following bowel resection surgery. When used with enhanced recovery after surgery (ERAS) protocol, alvimopan was shown to reduce length of stay (LOS) and hospital costs. However, if dosed inappropriately benefits may be outweighed by high cost. The recommended dosing regimen is 12 mg administered orally 30 minutes to 5 hours pre-operatively, followed by 12 mg orally twice daily until discharge or a maximum of 15 total doses. The purpose of this study was to characterize the use of alvimopan and evaluate post-operative outcomes.

Methods: This medication use evaluation is a quality improvement project and therefore exempt from approval by the Institutional Review Board. A medication administration report generated in the electronic health record identified all patients who received at least one dose of alvimopan between December 1, 2015 and May 31, 2016. This retrospective chart review evaluated type of surgery, LOS, number of pre-operative doses given, number of post-operative doses given, incidence of POI, opioid use for 7 consecutive days prior to surgery, and history of myocardial infarction (MI). LOS was defined as the total number of days between the date of surgery and the date of hospital discharge. Discharge summaries were utilized to determine the incidence of POI and the prior to admission medication list was reviewed for opioid use prior to surgery. A total of 34 patients were reviewed.

Results: Patients underwent one of the following surgeries: total colectomy, partial colectomy, ileostomy reversal, proctectomy, ileostomy, proctopexy, or whipple. Appropriate pre-operative doses were administered to 31 of the 34 total patients. Ten of these patients also received post-operative doses.

Three of the 34 patients only received post-operative doses. A total of 100 pre-operative and post-operative doses were administered during the six-month period, resulting in an average of 3 doses per patient. Six patients (17.6%) developed POI. Five of these patients received the recommended pre-operative dose; two also received post-operative doses (one received a total of 5 post-operative doses; one received 12 post-operative doses). The patient who received five post-operative doses received one 12 mg capsule orally once daily, as opposed to the recommended twice-daily dosing regimen. The average number of post-operative doses and average LOS were higher in the POI group when compared to the total study population. There were no patients who experienced an MI or had used opioids for seven consecutive days prior to surgery.

Conclusion: Alvimopan may reduce post-surgical LOS, decrease the incidence of POI, and reduce overall healthcare costs. Utilizing this medication appropriately with the ERAS protocol can benefit patients undergoing bowel resection surgery. It is important to reinforce the dosing of one 12 mg oral pre-operative dose followed by 12 mg orally twice daily until discharge or until reaching the maximum of 15 doses.

Poster Title: Evaluating presentation of medication risk and its association with patient understanding and clinical decision-making

Primary Author: Heena Mavani, University of Connecticut School of Pharmacy, Connecticut;
Email: heena.mavani@uconn.edu

Additional Author (s):
Albert Zichichi
Rachel Eyler

Purpose: Medication risk and benefit information is often presented to patients quantitatively. Recent research suggests that icon arrays, matrices of discrete icons representing at-risk populations, may increase understanding in subjects low in health numeracy. However, icon arrays have not been found to improve understanding in subjects both low in numeracy and graphical literacy. This study seeks to determine whether presenting data in a continuous, "spinner" format will further increase risk understanding, compared to the standard numerical or graphical formats. The study additionally assesses the impact of an increased risk understanding on clinical decision-making.

Methods: This study was submitted to the Yale Institutional Review Board and determined to be exempt. Surveys were collected in an outpatient primary care clinic and oral consent was obtained prior to participation. Subjects were presented clinical scenarios and risk information in three different formats: numbers only, icon arrays, and probability spinners. Participants were told of two equally efficacious pills. Pill A was associated with a 10 percent chance of nausea and vomiting and a 0.6 percent chance of serious infection requiring hospitalization; Pill B was associated with a 20 percent chance of nausea and vomiting and a 0.2 percent chance of serious infection requiring hospitalization. They were then asked to evaluate the risks and choose either Pill A or Pill B. Subjects were also asked to rate how much they liked their format of the risk presentation on a Likert scale. At the end of each survey a Subjective Numeracy Scale questionnaire, assessing the baseline numeracy of each participant, as well as a demographic questionnaire were completed. ANOVA and chi-squared analyses were used to compare groups, and multivariate linear and logistic regression were used to adjust for differences in baseline characteristics between groups.

Results: A total of 151 subjects (56.4 percent female, average 41.7 years) participated. There was a significant relationship between format and risk understanding. Those with spinner and icon array formats were able to answer more questions related to adverse events correctly compared to the numbers only format (b equals 0.33, P equals 0.044 and b equals 0.54, P equals 0.001 respectively). For clinical decision-making, subjects who received the spinner presentation were more likely to choose Pill A than the numbers only format (OR equals 3.96, P equals 0.006). There was no statistically significant difference in preference for Pill A in subjects that received icon arrays compared to numbers only (OR equals 1.56, P equals 0.33). Spinner and icon array groups rated their satisfaction of the presentation higher than the numbers alone group (b equals 0.91 and b equals 0.62 respectively, P less than 0.05).

Conclusion: Patients receiving spinners or icon arrays understood risk better and preferred these formats to those that received numbers only. Those who received spinners were more likely to "correctly" choose Pill A suggesting that these formats positively influenced clinical decision-making. Future research will incorporate spinners into clinical practice in order to help patients make complex decisions.

Poster Title: Syringe infusion pump safety in the neonatal intensive care unit

Primary Author: Joseph Rosano, University of Connecticut School of Pharmacy, Connecticut;
Email: joseph.rosano@uconn.edu

Additional Author (s):
Jeffrey Low

Purpose: Inadvertent clamping or occlusions can lead to clinically significant delays in therapy in vulnerable patient populations such as neonates when occlusion detection is delayed. The purpose of this study is to measure the sensitivity of the Medfusion 4000 syringe infusion pump of detecting an occlusion to enhance medication administration safety in the neonatal intensive care unit.

Methods: In this study, the Medfusion 4000 Wireless Syringe Infusion Pump was assessed utilizing BD syringe sizes of 10, 30, and 60 milliliters. The syringes were filled to a volume of 10, 25, and 50 milliliters respectively using Dextrose 10%. Microbore tubing was clamped shut at the end to mimic an occlusion at the site of entry to the patient. Each syringe size was trialed using two different Medfusion pumps under infusion rates of 0.1, 0.2, 0.5, and 1 mL/hr. The relative pressure setting of the pump, under which each syringe size and infusion rate were tested, was set at three occlusion detection limits; Normal (12psi/83kPa), Low (8psi/55kPa), and Very Low (4psi/28kPa).

Results: Time to occlusion detection was categorized into four groups based on infusion rate (0.1 mL/hr, 0.2 mL/hr, 0.5 mL/hr, 1 mL/hr). Variables evaluated were syringe size and occlusion detection limit. Across all groups, syringe size demonstrated a direct relationship with time to occlusion detection; as syringe size decreased time to occlusion detection decreased. When the occlusion detection limit was manipulated, notable differences were seen amongst groups. When calibrated to the most sensitive setting, very low (4psi/28kPa), occlusion detection occurred on average within one minute of beginning the infusion across all groups; changes in syringe size and infusion rate did not have an effect. At a given infusion rate, the 10 mL syringe showed the least difference in time to occlusion detection when set to normal or low detection limits. However, the 30 and 60 mL syringes showed a two to three fold difference in time to

occlusion detection when changed from the normal to the low-pressure settings, with more pronounced differences at lower infusion rates.

Conclusion: Changing the pressure setting, syringe size, and infusion rate of an intravenously administered medication via syringe infusion pump can result in changes in the time to occlusion detection. When infusions are set to flow at a certain rate due to clinical needs and properties of certain medications, changing occlusion detection limits are more effective than changing syringe size in occlusion detection. In an effort to maximize syringe pump efficacy in occlusion detection, pressure settings should be set to the lowest pressure setting available to detect an occlusion.

Poster Title: Clinical evaluation of proper 4-factor prothrombin complex concentrate (4-F PCC) use in adult patient

Primary Author: Jinjoo Kang, University of Connecticut School of Pharmacy, Connecticut; **Email:** jinjoo.kang@uconn.edu

Purpose: Four-factor prothrombin complex concentrate (4-F PCC), indicated for urgent reversal of coagulant factor deficiency induced by a vitamin K antagonist therapy with acute major bleeding or the need for urgent surgery, was added to the Baystate Medical Center drug formulary in January 2016. Its desirable pharmacokinetic profile including fast onset and effective decrease of International Normalized Ratio (INR) in an emergent situation allows for potential misuse, incomplete documentation, and/or inadequate monitoring. This study will assess prescribing patterns and provider monitoring of 4-F PCC in adult patients. These patterns will then be used to design interventions to guide appropriate use.

Methods: This quality improvement project will use data collected from a drug utilization evaluation which consists of a retrospective chart review of all adult patients who received 4-F PCC from January 2016 to May 2016 at Baystate Medical Center or Baystate Franklin Center. The following data will be collected: indication for 4-F PCC (active bleed vs. procedural vs. high bleed risk), source of bleed, reversing anticoagulant therapy, international normalized ratio (INR) levels before and after administration, timing of INR levels, vitamin K administration, free frozen plasma (FFP) administration, and medical service ordering 4-F PCC. Collected data will be analyzed to determine the following: 1. Type of anticoagulant reversal; 2. Prescribing patterns of indication for use; 3. Appropriate monitoring of INR before and after 4-F PCC administration; 4. Appropriate adjunctive vitamin K administration. The analysis will be used to guide future discussions about restrictions, need for education, and changes to the distribution process regarding appropriate 4-F PCC use. This study was excluded from needing Institutional Review Board approval because it is for quality improvement.

Results: A total of 44 patients were administered four-factor prothrombin complex concentrate (4-F PCC). Forty-two patients were on warfarin, one patient on apixaban, and one patient on no oral anticoagulant therapy. Average initial INR was 3.3 (range 1.1 to 9.6), with four patients

with an initial INR below 2.0. Twenty-five patients were indicated with an active bleed, 16 patients with a procedural INR reversal, and 10 patients with a high risk of bleed with an elevated INR. Forty-three percent of patients administered 4-F PCC had incomplete monitoring of INR and/or lacked adjunctive vitamin K administration. Twenty six 4-F PCC orders were completed by the emergency and trauma team, twelve were ordered by a surgical team, and five were by an intensive care team.

Conclusion: Four-factor prothrombin complex concentrate (4-F PCC) has been used in a diverse patient population including those who are not indicated for its use. Incomplete therapy and monitoring have also been shown. Continued education, especially with the emergency and trauma team, and development of an institutional algorithm for 4-F PCC use is recommended to ensure consistent methods of therapy and complete overall treatment.

Poster Title: De-escalation of vancomycin in patients with neutropenic fever

Primary Author: Lindsey Parker, University of Connecticut School of Pharmacy, Connecticut; **Email:** lindsey.parker@uconn.edu

Additional Author (s):
Jola Mehmeti
Trinh Pham
Sarah Perreault
Dayna McManus

Purpose: The Infectious Diseases Society of America (IDSA) and National Comprehensive Cancer Network (NCCN) guidelines recommend the addition of vancomycin as empiric therapy in neutropenic fever (NF) patients with pneumonia, catheter-related infections, severe mucositis or who are hemodynamically unstable. To reduce the risk of resistance developing, the guidelines recommend that vancomycin be discontinued after 48 hours if resistant Gram-positive bacteria are not cultured from the patient. The purpose of this study is to assess the incidence of vancomycin discontinuation at 48 hours in NF patients if no resistant Gram-positive organisms are identified.

Methods: This retrospective chart review looked at a sample of patients between September 1, 2015 and January 1, 2016 who met criteria for neutropenic fever and received an antipseudomonal agent with vancomycin. Patients were excluded if they were < 18 years old, did not meet the criteria for neutropenic fever, or if they received aztreonam and vancomycin. Baseline information that was collected included diagnosis, chemotherapy regimen, prior history of methicillin-resistant Staphylococcus aureus (MRSA), collection of MRSA swab, positive cultures, discontinuation of vancomycin at 48 hours, duration of vancomycin past the 48 hours, whether vancomycin was restarted after initial discontinuation, recommendations from the infectious disease team or the antibiotic stewardship team (AST), and if recommendations were followed. This was a quality improvement project within our department which is exempt from IRB approval.

Results: A total of 78 admissions were assessed. Twenty admissions (4 without fever, 15 without neutropenia, 1 receiving aztreonam/vancomycin) failed to meet criteria and were excluded. Vancomycin was appropriately discontinued at 48 hours in 57% (33/58) of admissions. Of the 43% (25/58) of admissions who were continued > 48 hours, 12 received vancomycin for < 5 days, 3 for 5 days, 5 for 6-7 days, 3 for 8-10 days, and 2 for > 10 days. Multiple reasons were cited for continuation, persistent fevers being the most common. MRSA swabs were collected in 71% (41/58) of admissions. Of these, 2 swabs were positive for MRSA, neither of which translated into positive blood cultures. Six patients were restarted on vancomycin for fever after discontinuation, with 4 patients restarted once and two patients restarted twice. Infectious Diseases was consulted on 17 patients, with recommendations followed on 15 patients and no vancomycin recommendation made on 2 patients. AST recommended discontinuation of vancomycin on 5 patients, all of which were accepted.

Conclusion: Based on the results of this study, there is an opportunity for improvement in discontinuation of vancomycin at 48 hours in NF patients at our institution. To improve our rates, clinical pharmacists will assess all vancomycin ordered for NF at 48 hours. In conjunction with AST, notes will be placed in the chart providing recommendations to de-escalate vancomycin in patients that do not meet criteria for continued vancomycin usage.

Poster Title: Comparison of insulin glargine 300 units/ml versus insulin glargine 100 units/ml – A systematic review

Primary Author: Stefanie Zassman, University of Connecticut School of Pharmacy, Connecticut; **Email:** stefanie.zassman@uconn.edu

Additional Author (s):
Fei Wang
Philip Goldberg

Purpose: To review the available evidence on the clinical efficacy and safety of a more concentrated insulin glargine [rDNA origin] injection 300 units/ml compared to insulin glargine 100 units/ml in patients with type 1 and type 2 diabetes mellitus.

Methods: The following electronic databases were searched: PubMed and MEDLINE (using Ovid platform), Scopus, BIOSIS, and Google Scholar through June 2016. Conference proceedings of the American Diabetes Association (ADA; 2015-2016) were reviewed. We also manually searched reference lists of pertinent reviews and trials.

Results: A total of 6 pivotal phase 3 randomized controlled trials known as the EDITION series were reviewed. All of these trials (n=3500) were head-to-head comparisons evaluating the efficacy and tolerability of glargine 300 units/ml versus glargine 100 units/ml in a diverse population with type 1 and type 2 diabetes mellitus. These trials were of six months duration with a 6-month safety extension phase.

Conclusion: Glargine 300 units/ml was as effective as Glargine 100 units/ml for improving glycemic control over 6 months in all studies, with a lower risk of nocturnal hypoglycemia significant only in insulin-experienced patients with type 2 diabetes. Overall, patients on glargine 300 units/ml required 10% to 18% more basal insulin, but with less weight gain compared with glargine 100 units/ml.

Poster Title: Conversion of intrathecal to oral baclofen after a surgical site infection following intrathecal pump placement

Primary Author: Chelsea Bast, University of Connecticut School of Pharmacy, Connecticut; **Email:** chelsea.bast@uconn.edu

Additional Author (s):
Stephanie Cheok
Kent Owusu
Emad Nourollah-Zadeh

Purpose: This case report describes a method of rapid conversion of intrathecal baclofen to oral baclofen in a patient with multi-site infection necessitating intrathecal pump removal. Significant past medical history included cerebral palsy with spastic quadriplegia complicated by seizures and joint contractures. Motor symptoms were well controlled with intrathecal baclofen pump insertion approximately five years prior to presentation in the setting of insertion site infection. As abrupt discontinuation of baclofen has resulted in withdrawal symptoms including death, careful taper of intrathecal baclofen with appropriate monitoring is paramount. Monitoring during the conversion included use of the modified Ashworth grading scale to characterize spasticity and monitoring for baclofen withdrawal syndrome, including vital signs and creatine kinase. The multidisciplinary team planned to decrease intrathecal dose by 15-25 percent per day over five days while overlapping with titration of oral baclofen. Baseline intrathecal baclofen daily dose was 912.8 micrograms (mcg) with a modified Ashworth grade of 3. Oral baclofen was initiated on day one of intrathecal baclofen taper at a dose of five milligrams (mg) three times daily. On day two, daily dose of intrathecal baclofen was decreased to 701 mcg and oral baclofen was increased to 10 mg three times daily. On day three, the intrathecal baclofen dose was decreased to 553.1 mcg daily. However, the patient experienced tachycardia around 120 beats per minute and systolic blood pressure of 156 mm Hg hours after intrathecal baclofen dose reduction. To mitigate signs of baclofen withdrawal syndrome, intravenous (IV) diazepam was initiated with good response. The patient's heart rate and blood pressure returned to baseline values. Following day four taper of daily intrathecal baclofen dose to 350 mcg, both heart rate and blood pressure increased similarly to the previous day. Increased spasticity was noted on day four as evidenced by a measured modified Ashworth

grade of 4. IV diazepam was utilized to ameliorate withdrawal symptoms with moderate response. However, due to labile blood pressure and tachycardia suggesting baclofen withdrawal syndrome, intrathecal baclofen taper on day five was interrupted to allow for further up-titration of oral baclofen dose to 30 mg three times daily. Daily dose of intrathecal baclofen was decreased to 175 mcg on the following day as oral baclofen dose was increased to 35 mg three times daily. Patient appeared to be stable upon further assessment of withdrawal symptoms. Intrathecal baclofen was discontinued on day seven with continuation of oral baclofen 35 mg three times daily and IV diazepam as needed for spasticity. Despite the high risk of withdrawal symptoms associated with abrupt discontinuation of baclofen, there is a lack of guidance on how to successfully discontinue this agent. This case illustrates a multidisciplinary approach in rapid discontinuation of intrathecal baclofen in the setting of surgical site infection. Other clinicians may follow a similar approach in the event an urgent discontinuation of intrathecal baclofen is warranted.

Poster Title: Barriers to delivering comprehensive medication therapy management services implemented in Connecticut community pharmacies

Primary Author: Sarah Leverett, University of Connecticut School of Pharmacy, Connecticut; **Email:** sarah.leverett@uconn.edu

Additional Author (s):
Thomas Buckley
Marissa Salvo

Purpose: There are countless barriers to patients receiving comprehensive healthcare. Community pharmacists are the most accessible healthcare professionals, and therefore have the ability to provide services to their patients effectively and efficiently. This project demonstrated the benefit of community pharmacists' involvement in delivering comprehensive medication therapy management (MTM) services for patients with hypertension and diabetes. An evaluation of pharmacists' opinions was conducted after the first cohort of pharmacies engaged in the project to determine any changes that can be made for the next cohort to improve efficiency and success.

Methods: A partnership between the state department of health, the University of Connecticut School of Pharmacy, and statewide independent pharmacies created a network of providers to deliver MTM services to underserved patients in Connecticut. Pharmacists completed a practice-based certificate program through the School of Pharmacy to provide MTM services for patients with diabetes and hypertension. Each pharmacist met with ten patients and documented demographics, monitoring parameters, medications, drug therapy problems, and interventions. Pharmacists documented adherence at the first and last visit by using the Morisky Scale. The pharmacists had up to four patient encounters over 12 months with a goal of improving drug therapy outcomes, adherence, and clinical outcomes. The first cohort of five pharmacists was interviewed to determine the strengths and weaknesses of the project's methodology before inclusion of the next cohort of pharmacists. A uniform survey with multiple choice answers was presented to the pharmacists in a twenty minute phone interview. The pharmacists addressed physical, logistical, and patient-related barriers, and were encouraged to elaborate on how to improve the process in these categories. Specifically,

pharmacists were asked about barriers such as transportation, incentivizing return, access to medical providers and medical information, ease of use of documentation form, confidence in their delivery of the service, disruption of workflow logistics, and patient language and health literacy.

Results: The MTM service was conducted in low-income, urban areas in Connecticut, so transportation was a common issue among all pharmacists. Patients often relied on public transportation, friends and family members, or walked to attend appointments. The pharmacists provided up to 40 dollars per patient to incentivize visit retention. Pharmacists were allowed discretion on how to divide the budget, and overall felt it was effective. All pharmacists reported difficulty in obtaining lab values from doctors' offices; however, some were patient self-reported. Pharmacists suggested sending a letter to medical offices prior to patient visits to ensure participation of providers and request pertinent information. Pharmacists reported difficulty in carving out time to provide an efficient service. Most pharmacists felt comfortable providing MTM services, but would benefit from periodic conference calls from project coordinators to discuss barriers. The most common patient-related barrier was health literacy, leading to a misunderstanding or indifference about their health and medications.

Conclusion: As community pharmacists become more involved in direct patient care, it is important to determine potential obstacles to delivering effective care. In underserved populations, providers encounter barriers in transportation and health literacy when meeting with patients and educating about personal health goals. In community pharmacies, barriers exist in sharing information with other providers due to privacy laws and lack of standardized health records. Improving efficiency of pharmacist time management and patient scheduling will optimize the ability of community pharmacies to provide comprehensive MTM services, leading to improved patient outcomes.

Session-Board Number: 2-014

Poster Title: Hemodynamic effects of dexmedetomidine compared to propofol in neurocritical care

Primary Author: Albert Zichichi, University of Connecticut School of Pharmacy, Connecticut;
Email: albert.zichichi@uconn.edu

Additional Author (s):
Carolina Maciel
Kent Owusu

Purpose: Adequate sedation in neurocritical care is usually achieved with sedatives such as propofol and dexmedetomidine. Propofol (PRO) is limited by severe hemodynamic adverse effects and may accumulate with prolonged use leading to hypertriglyceridemia, cardiac failure, metabolic acidosis, renal failure, and rhabdomyolysis. Dexmedetomidine (DEX) allows patient arousal for frequent neurologic examinations without interruption of treatment. DEX is also associated with hemodynamic adverse effects. Despite the perceived benefits, the tolerability of DEX in neurocritical care patients has not been well described. The purpose of this study was to evaluate the hemodynamic effects of dexmedetomidine compared to propofol in neurocritical care patients.

Methods: Patients greater than or equal to 18 years old who received either dexmedetomidine or propofol in the neurointensive care unit were included in this study. Due to restrictive use criteria for DEX at the study institution, patients who were initiated on DEX over a period of 14 months were identified for inclusion. Based on that sample size, an equal number of patients started on propofol were included using a computerized randomization model. The primary outcome measures were the incidence of hypotension (SBP less than 90 mm Hg), hypotension requiring vasopressor intervention and bradycardia (HR less than 60 mm Hg). Secondary outcome measures including mean duration of mechanical ventilation, mean duration of continuous infusion sedation and the median duration of ICU length of stay.

Results: A total of 70 subjects (35 patients in each arm) participated in the study. The mean age (years) between the DEX and PRO arm did not differ significantly (51.1 vs. 57.4, P equals 0.08). There was no statistically significant difference in hemodynamic adverse events between DEX

and PRO treatment arms: hypotension (23 percent vs. 17 percent, P equals 0.77), hypotension requiring vasopressor (9 percent vs. 9 percent, P equals 1) or bradycardia (49 percent vs. 34 percent, P equals 0.33). Duration of mechanical ventilation did not vary between the PRO group or the DEX group (9.3 days vs. 8.6 days, P equals 0.29). There was no difference in the mean duration of sedation between the DEX and PRO groups (43 hours vs. 37 hours, P equals 0.21), median duration of ICU length of stay (9 days vs. 9 days respectively) or mean in-hospital mortality (6 percent vs. 15 percent, respectively P equals 0.43). One patient in the PRO group experienced objectively defined propofol related infusion syndrome.

Conclusion: This retrospective study showed no statistically significant differences in hemodynamic effects between DEX when compared to PRO in neurocritical care patients. This study was likely underpowered to detect a statistically significant difference in hemodynamic effects between treatment arms. The majority of evidence supporting the use of DEX for sedation in the neurocritically ill is limited to prospective observational studies with small samples sizes and case reports. More studies assessing the hemodynamic effects of dexmedetomidine are needed in this patient population.

Poster Title: Evaluation of isavuconazole, a new triazole antifungal, in the solid organ transplant population: a systematic review

Primary Author: Victoria Stevens, University of Connecticut School of Pharmacy, Connecticut;
Email: victoria.stevens@uconn.edu

Additional Author (s):
Jason Funaro
Alison Blackman
Abigail Zeiner
Michael Nailor

Purpose: Solid organ transplant (SOT) recipients are at an increased risk for invasive fungal infections due to use of immunosuppressive therapies. Managing antifungal therapy in the post-transplant setting is particularly challenging due to the adverse effect profiles and high propensity for drug interactions with available agents. These issues are further confounded by differing spectrums of activity among licensed antifungal agents. Isavuconazole is the active moiety of isavuconazonium sulfate, which is a newly approved triazole antifungal for treatment of invasive aspergillosis and mucormycosis. The purpose of this evaluation is to assess the use of isavuconazole in the SOT population.

Methods: Preclinical in vitro studies, clinical trials, and review articles were identified through a systematic MEDLINE search on June 5, 2016 using search terms "ISAVUCONAZOLE", "BAL4815", "BAL8557", "ISAVUCONAZONIUM", "RO-0098557", and "RO-094815" for all dates in the database. The search was only restricted to those in the English language. In order to capture all relevant material for this recently approved drug, no disease specific modifying terms were used for exclusion.

Results: A total of 150 articles were identified through this search. The oral formulation has a bioavailability of 98% and absorption is not saturated at clinically relevant dosing. This property allows for conversion to oral dosing as soon as the patient is able to tolerate oral medications. Isavuconazole is a broad-spectrum antifungal agent with in vitro activity against clinically relevant fungi in the transplant population, including Candida species, Aspergillus species, and

non-Candida yeast, non-Aspergillus moulds, including mucormycetes, and dimorphic fungi. Immunosuppressed patients, mostly hematologic malignancies, were included in phase II and phase III clinical trials that demonstrated non-inferiority to fluconazole and voriconazole for the treatment of candidiasis and aspergillosis respectively. Separate trials demonstrated efficacy for the treatment of mucormycosis, cryptococcosis, and dimorphic fungi in humans in limited data sets. Phase III trials indicated less hepatobiliary and ocular effects compared to voriconazole. Through moderate inhibition of cytochrome-P450 3A4 and inhibition of uridine diphosphate-glucuronosyltransferases, isavuconazole can increase the levels of related substrates. Isavuconazole increases the area under the curve of cyclosporine, tacrolimus, and sirolimus by 1.29, 2.25, and 1.84 fold respectively. Voriconazole increases these three drugs by 1.7, 3-10, and 7-11 fold, while posaconazole increases them by 1.33, 3.6, and 7.9 fold respectively.

Conclusion: Although not studied specifically in SOT patients, isavuconazole has demonstrated treatment efficacy in severely immunosuppressed patients suggesting it could have a role in both treatment and prophylaxis in the appropriate SOT population. Isavuconazole has been shown to have less adverse reactions that lead to discontinuation of study drug in phase III trials compared to voriconazole. Additionally, isavuconazole has a similar drug interaction and adverse effect profile to fluconazole; however, it is considered to have a significantly improved drug interaction profile compared to that of voriconazole and posaconazole.

Poster Title: Assessing the potential role of the community pharmacist in lowering blood pressures in underserved communities

Primary Author: Michael France, University of Connecticut School of Pharmacy, Connecticut;
Email: michael.france@uconn.edu

Additional Author (s):
Joseph Iovine
Laks Pudipeddi
Frank Boskello
Rachel Eyler

Purpose: About 75 million American adults have high blood pressure and only 54 percent of people with this diagnosis have achieved adequate blood pressure control. Pharmacists, as one of the most accessible health care professionals in the community, have a unique opportunity to help these patients reach their blood pressure goals. This study, as part of the Association of State and Territorial Health Official's "Million Hearts Initiative" investigated how community pharmacists can engage underserved populations to help lower blood pressure through various services including patient outreach, blood pressure monitoring, and medication therapy management (MTM).

Methods: This study investigated the utility of three different approaches to engaging the community in an effort to reduce the prevalence of high blood pressure. The study was conducted in a community pharmacy in Bridgeport, Connecticut, and services were performed by pharmacy students under the supervision of a licensed pharmacist. Patients were selected through a database screening of those on antihypertensive medications including beta-blockers, angiotensin converting enzyme inhibitors, angiotensin II receptor blockers, diuretics, and calcium channel blockers. Patients were then contacted via telephone to discuss blood pressure control and medication use. At the end of the conversation, patients were offered the opportunity for a blood pressure measurement and MTM. Recommendations were communicated to patients' physicians, and patients scheduled a follow-up appointment with the pharmacy for a second blood pressure reading and consultation. As a second recruitment strategy, fliers were created and attached to prescription bags of those with hypertension

encouraging them to speak to a pharmacist for help in managing blood pressure. Thirdly, pharmacy students were partnered with community health workers to measure blood pressure in public areas (such as libraries, barber shops, and food pantries) and assessed community attitudes regarding the pharmacist's potential role in helping to manage blood pressure.

Results: Pharmacy students initiated 387 phone calls and successfully reached fifty patients via telephone over a twenty-four-day period. Fifteen patients had concerns regarding their blood pressure and medications. Concerns included side effects, efficacy, and dosage. Of the fifty patients spoken to, sixteen came into the pharmacy for a blood pressure reading and MTM session. Drug therapy problems identified during MTM sessions were medication nonadherence (5 patients), undesirable side effects (5 patients), and high blood pressure readings as defined by JNC-8 guidelines (7 patients). A total of nineteen interventions were made for nine patients. Interventions included changing medications (4), providing pill boxes (4), scheduling doctor appointments (7), and medication administration counseling (3). Only 3 patients returned to the pharmacy for their scheduled follow-up, and all 3 had reductions in blood pressure. Of the patients spoken to with the community health workers, 95.6 percent believed pharmacists and physicians should be working together to manage health conditions and medication use.

Conclusion: Most patients are receptive to having a pharmacist involved in monitoring blood pressure. Utilizing blood pressure monitors in the pharmacy, offering MTM to patients, and actively collaborating with patients' physicians may lead to better health outcomes. Collaboration between pharmacists, community health workers, and other healthcare professionals, can have a large impact on hypertension control in underserved populations.

Submission Type: Evaluative Study

Session-Board Number: 2-017

Poster Title: Identification of patient risk factors for trimethoprim-sulfamethoxazole resistant Staphylococcus aureus infections

Primary Author: Meghan Gagnon, University of Connecticut School of Pharmacy, Connecticut;
Email: meghan.gagnon@uconn.edu

Additional Author (s):
Andrew Reuter
Jeffrey Aeschlimann

Purpose: The spread of antibiotic resistance is a major threat to public health. Staphylococcus aureus infection is an increasingly common cause of both hospital and community-acquired infections. Many of these infections are treated with trimethoprim-sulfamethoxazole as it has potent and reliable activity against gram-positive pathogens (including methicillin-resistant S. aureus). Sulfamethoxazole-trimethoprim has historically been used in a variety of healthcare settings due to advantages such as patient tolerance, low expense and ease of administration. We evaluated possible risk factors for trimethoprim-sulfamethoxazole resistant S. aureus infections, as resistance to this medication removes one of the preferred oral options for treating these infections.

Methods: This was an institutional review board approved retrospective case-control study conducted at UConn John Dempsey Hospital. Case patients were admitted from 2012 to 2016 and were infected with trimethoprim-sulfamethoxazole resistant S. aureus. The control group consisted of patients who were admitted within 1-2 days of case patients, and who had trimethoprim-sulfamethoxazole sensitive S. aureus infections. Cases were matched 1:2 with controls in order to improve the power of this study. Data were collected on a total of 27 potential risk factors. These risk factors were chosen based on prior published studies as well as pertinent comorbidities which have proven to increase the risk of antibiotic-resistant infections. Two study investigators collected data independently using information from the hospital's electronic medical record. Descriptive statistics, univariate and multivariate statistical analysis were performed using Minitab and SPSS statistical software. Independent risk factors were considered statistically significant if the P-value was less than 0.05. Binomial multivariate logistic regression analysis was performed to determine the odds ratios for risk factors and to

control for covariance and confounding variables. Risk factors with P-values of < 0.2 on univariate analysis were included in the multivariate analysis.

Results: Twenty-two cases of trimethoprim-sulfamethoxazole resistant S. aureus infections were matched with 44 control cases of trimethoprim-sulfamethoxazole sensitive S. aureus infections. Baseline characteristics for cases and controls, respectively, were; mean age in years (58.6, 58.5), male gender (68.2%, 68.2%), caucasian (77.3%, 79.5%), BMI greater than 30 (18.2, 36.2), and mean length of stay (13, 9.5 days). The most common infection sites for case and control arms respectively included tissue (31.8%, 38.6%), blood (18.2%, 25%), lung (38.1%, 27.3%). Trimethoprim-sulfamethoxazole resistant S. aureus had significantly higher resistance to oxacillin, cefazolin, clindamycin, gentamicin, levofloxacin, and tetracycline. Most cases (73%) were identified in 2013-2014, and an increase in resistant infection prevalence over time was not observed.The following risk factors displayed statistically significant P values (less than 0.05) upon univariate analysis: urinary tract infection, HIV infection, previous trimethoprim-sulfamethoxazole therapy in the past 1 or 6 months, and admission from community or a correctional facility. In multivariate analyses, only urinary tract infection (OR=28, 95% Cl 3-294) and previous trimethoprim-sulfamethoxazole in the last 6 months remained statistically significant (OR=14, 95% CI 1.2-179).

Conclusion: Multivariate analyses of data from our patients indicated that only urinary tract infection and previous trimethoprim-sulfamethoxazole use in the last 6 months were statistically significant risk factors for trimethoprim-sulfamethoxazole resistant S. aureus infections. Although recognition of these patient factors will be important to improve the treatment of patients at our institution, larger studies across other cohorts of hospitalized and/or community patients may help identify a more comprehensive list of risk factors.

Poster Title: Coexistence of advanced age, chronic kidney disease, and reduced body weight in patients with atrial fibrillation

Primary Author: Mark Wysocki, University of Connecticut School of Pharmacy, Connecticut;
Email: mark.wysocki@uconn.edu

Additional Author (s):
Sora Han
Rafay Ali
Iregi Francis
Christine Kohn

Purpose: Novel oral anticoagulants (NOACs) have standard and reduced dose regimens for stroke prevention in atrial fibrillation (AF) patients. Determination of NOAC dosing requires that clinicians assess patients for the presence of advanced age, decreased renal function, and reduced body weight (either as separate components or as part of the calculation for creatinine clearance). Little is known about the frequency in which these dose reduction criteria occur in patients with AF. The purpose of this study was to quantify the prevalence of comorbid advanced age, moderate-severe chronic kidney disease (CKD), and reduced body weight among patients with AF.

Methods: This retrospective claims analysis was performed in the Agency for Healthcare Research and Quality's 2012 National Inpatient Sample (NIS). The NIS, designed to approximate a 20 percent stratified sample of United States community hospitals, is the largest all-payer inpatient database in the United States and contains all discharge data from more than 1200 hospitals across 44 states. Adult patients were included if they had a diagnosis of AF (indicated with the presence of an International Classification for Diseases, ninth-edition, Clinical Modification (ICD-9-CM) code of 427.31 in any position). Only patients with an ICD-9 code indicating BMI (V85.0 to 85.4) were included in this analysis. CKD was identified by the presence of ICD-9 codes ranging from 585.1 to 585.9 as well as procedural codes for dialysis or kidney transplant, and was categorized into stages 1 through 5. Patients were then characterized into the following categories: advanced age (greater than or equal to 80 years), moderate-severe CKD (defined as stages 3, 4, or 5), and underweight (BMI less than 19 kilograms per meter

squared). The proportion of AF patients with zero, one, or multiple characteristics that would merit dose reduction were determined and are reported as percentages with 95 percent confidence intervals (CIs).

Results: We identified 751,009 AF patients in the 2012 NIS, of which 37,951 patients had available BMI data and were included in our analysis. Patients' median and 25, 75 percent CHA2DS2-Vasc and ATRIA bleeding scores were 4 (3, 5) and 3 (1, 6), respectively. Median and 25, 75 percent age was 75 years old (66, 83) with 36.4 percent of patients greater than or equal to 80 years of age. The overall prevalence of moderate-severe CKD was 16.2 percent, and 21.6 percent of patients had a BMI less than 19 kilograms per meter squared. Among patients with reported BMI data, 15,920 (41.9 percent) did not have a NOAC dose adjustment risk factor, 13,608 (35.9 percent) had one risk factor, 7,289 (19.2 percent) had two risk factors, and 1,134 (3.0 percent) had all three risk factors. Of patients with 2 NOAC dose adjustment criteria, advanced age plus reduced body weight was the most common, appearing in 3,777 hospitalizations (51.8 percent).

Conclusion: In our current real-world analysis of AF patients, almost a quarter (22 percent) of the patients met two or more of the criteria indicating that NOAC dose reduction may be warranted. Further research is needed to assess the frequency of NOAC dose adjustment and its implications on clinical practice.

Session-Board Number: 2-019

Poster Title: Title: Cardiovascular safety of glucose lowering drugs (GLD) in patients with type 2 diabetes and cardiovascular disease – a network meta-analysis

Primary Author: Daniel De Lena, University of Connecticut School of Pharmacy, Connecticut;
Email: de92len@yahoo.com

Additional Author (s):
Sharif Jalil
Jola Mehmeti
Fei Wang
Tiansheng Wang

Purpose: This study will assess the extent to which GLDs increase the risk of hospitalization for heart failure (HHF), cardiovascular (CV) death, and all-cause mortality in patients with type 2 diabetes and established cardiovascular disease (CVD).

Methods: Literature Search
Eligible trials were identified through electronic databases performed in PubMed and Scopus for randomized controlled trials available up to September 2016 in the English language. We also manually searched the references of cited articles.
Study design
We performed a network meta-analysis (NMA) using a frequentist model. Network meta-analysis integrates data from direct comparisons of treatments within trials and from indirect comparisons of interventions assessed against a common comparator in different trials to compare all investigated GLDs.
Inclusion
Eligible studies met the following inclusion criteria: 1) Phase III and Phase IV RCTs in type 2 diabetes with established CVD; 2) follow-up > 24 weeks and at least 100 patients per arm; 3) reported the following CV outcomes: HHF, CV death, and all-cause death; 4) comparison of GLDs relative to placebo or another GLD; 5) restricted to full-text publications in the English language.
Outcomes

1) HHF; 2) CV death; and 3) all cause death (includes CV and all-cause deaths that occurred as a primary endpoint event).

Data synthesis

We performed a random-effects network meta-analysis, assuming a common heterogeneity variable for all comparisons. We conducted network meta-analysis with STATA version 13 using the mvmeta command and programmed STATA routines.

Results: Our search identified 846 potentially relevant studies. After excluding duplicates and the initial screening of titles, 85 studies remained for screening. A total of 12 RCTs were eligible for network meta-analysis. Our final analysis included 69394 patients.

For HHF, our NMA results showed that SGLT2i had a significant lower risk compared to placebo (OR 0.65, 0.48 to 0.88), DPP-4i (OR 0.57, 0.41 to 0.80) and TZD (OR 0.46, 0.30 to 0.70). TZDs had a significant higher risk of HHF compared to placebo (OR 1.42, CI 1.07 to 1.89) and GLP1-RA (OR 1.52, 1.09 to 2.11), and SU (OR 2.43, CI 1.20 to 5.0).

For CV death, SGLT2 was associated with a significant lower risk of CV death compared to placebo (OR 0.61, 0.48 to 0.78), DPP-4i (OR 0.61, 0.46 to 0.81), GLP1-RA (OR 0.70, 0.52 to 0.94), and TZD (OR 0.64, 0.45 to 0.90).

For all-cause mortality, both GLP1-RA and SGLT2i had a significantly lower risk compared to placebo (OR 0.89, 0.78 to 1.01 and OR 0.69, 0.56 to 0.85, respectively). SGLT2i was associated with a lower risk compared to DPP-4i (OR 0.67, 0.53 to 0.85), GLP1-RA (OR 0.77, 0.61 to 0.98), and TZDs (OR 0.72, 0.53 to 0.97).

Conclusion: Our network meta-analysis included direct and indirect comparisons of GLDs for risk of cardiovascular events. Our results show that SGLT2i are associated with a lower risk of HHF, CV death, and all-cause death compared to placebo, TZD, DPP4i, and GLP1-RAs. GLP1-RA is associated with a lower risk of HHF compared to TZD and placebo.

Poster Title: An evaluation of the prescribing and monitoring of dabigatran within the Veterans Affairs Connecticut Healthcare System (VACT)

Primary Author: Jordan DeAngelis, University of Connecticut School of Pharmacy, Connecticut; **Email:** jordan.deangelis@uconn.edu

Additional Author (s):
Catherine Kulis-Robitaille
Seth Cioffi
Jaime Correia

Purpose: In 2010, dabigatran became the first direct oral anticoagulant (DOAC) to receive FDA approval for stroke risk reduction in patients with non-valvular atrial fibrillation. The Veterans Affairs Pharmacy Benefits Management published the initial dabigatran criteria for use (CFU) document in 2011 for agency use. Since then, three DOACs have received FDA approval. Indications for these agents have increased and the healthcare system's CFU of these agents have been revised several times. As a quality management assessment aimed at improving healthcare provision, this medication use evaluation (MUE) intends to review the appropriate prescribing and monitoring of dabigatran therapy.

Methods: This retrospective chart review will include all patients with active outpatient prescriptions for dabigatran as of September 1, 2016. A comprehensive search found 296 patients, 50 of which were randomly selected for sampling. The following information was collected from the Computerized Patient Record System (CPRS): patient's age; most recent serum creatinine (SCr), complete blood count (CBC), and actual body weight; and date dabigatran was initiated. Patients with objective data that was missing or conflicted with the CFU were labeled as requiring further review.

Results: A total of 50 patient charts were reviewed retrospectively. Of these patients, 50% were identified as requiring further review. The majority of these patients (42%) were found to have met at least one of the criteria for apixaban or rivaroxaban as outlined in the CFU. A small number of patients (6%) met two or more criteria to be eligible to receive apixaban or rivaroxaban. Approximately one-third (34%) of patients were 75 years of age or older, meeting

the DOAC CFU for apixaban use. The most current reported labs in CPRS showed 8% of patients with an elevated SCr of 1.5 mg/dL or greater and 6% of patients with a calculated creatinine clearance between 30-50 mL/min. The DOAC CFU recommends monitoring of the CBC and SCr at least annually or more frequently in certain patient populations, but 14% of patients were found to either not have the necessary labs reported in CPRS or to have gaps in their lab monitoring history greater than 12 months.

Conclusion: After the introduction of the newer DOACs and revisions to the CFU, patients previously initiated on dabigatran were never reassessed under the latest guidance. Furthermore, dabigatran continues to be initiated in patients for whom the CFU recommends apixaban or rivaroxaban. Based on the findings of this MUE it is recommended that the MUE be expanded to review the prescribing and monitoring of all patients receiving dabigatran at VACT. Future recommendations may include expanding the MUE to include all DOACs and providing the necessary education to all prescribers and pharmacists.

Poster Title: Integration of a virtual dispensing simulator "MyDispense" in an experiential education program to improve medication safety

Primary Author: Ashley Johnson, University of Connecticut School of Pharmacy, Connecticut;
Email: ashley.e.johnson@uconn.edu

Additional Author (s):
Jill Fitzgerald
Lisa Holle
Mary Ann Phaneuf
Diana Sobieraj

Purpose: Technology is increasingly used within healthcare education. To better equip students with tools and skills to fully integrate into a rapidly advancing field, preceptors must embrace new teaching technologies. Benefits of using technology in experiential settings include allowing learners to safely make errors that do not harm patients and providing immediate feedback to enhance learning. The objective of this study was to evaluate student learning and preparedness for community introductory pharmacy practice experiences (IPPEs) after implementation of an online virtual dispensing software "MyDispense" into experiential education for first-year pharmacy students enrolled at the University of Connecticut (UConn) School of Pharmacy.

Methods: The Institutional Review Board approved this study. Both first-year pharmacy students and their assigned community IPPE preceptors were eligible. After completing a demographic survey, students were stratified into 4 groups based on previous community pharmacy experience and then randomized to complete MyDispense exercises before starting IPPE or after 24-32 hours of IPPE. Groups A and C included students with greater than 50 hours of previous community pharmacy experience; Group B and D students had less than 50 hours. Groups A and B students were granted access to MyDispense at time of rotation assignment and were required to complete 40 exercises before arriving at assigned site. Group B and D students were granted access to MyDispense following completion of preceptor student readiness survey or when preceptor declined to participate. Preceptor participants were blinded to their student's assigned group and were required to complete a 6-item student

readiness survey after student completed 24-32 IPPE hours. Regardless of preceptor involvement, all student participants were granted 10 hours towards their IPPE requirement, contingent upon completion of all MyDispense exercises. Following completion of exercises, students were asked to complete an anonymous 8- item survey evaluating their performance and use of MyDispense. Study data was then compiled for review. All surveys were administered using Qualtrics. Descriptive statistics were used to characterize data; Mann-Whitney U test was used to calculate P values.

Results: Between November 2015 through April 2016, 88 students and 27 preceptors elected to participate in the study. Groups A and C each contained 18 students and Groups B and D contained 26 students. Of the 88 students, 37 (42%) currently worked or had previously worked in a community pharmacy. Overall, students felt confident in their ability to manage the assigned tasks (gather and organize data, evaluate/process prescription, interpret abbreviations, select product, counsel on self-care and medication) with median scores of 3-4 (5-point Likert scale). All students appreciated that MyDispense offered a safe environment to build skills without bearing potential harm to patients (median score 5, of 5-point Likert scale). Preceptors displayed less confidence in students in their ability to managed assigned tasks with median scores of 2-4 (5-point Likert scale) regardless of previous experience or when MyDispense exercises completed. Specifically preceptors rated students with lower scores on dispensing activities than students (P < 0.001), but not counseling activities. However, students who completed the MyDispense exercises before rotation (Groups A/B) received higher scores from preceptors regarding patient counseling than those who did MyDispense exercises after starting rotation (Groups C/D, P < 0.0047).

Conclusion: Simulation-based software, such as MyDispense, can be an effective teaching tool for students embarking on community practice rotations, which allows the student to safely make errors and receive immediate feedback. This virtual setting can enhance learner understanding of medication safety. With the increase in community and specialty pharmacies within healthcare systems, MyDispense offers the ability for preceptors to use the software to enhance rotation education and improve understanding of medication safety.

Poster Title: From prison to the community: Opportunities for pharmacists to support inmate medication adherence

Primary Author: Elliott Bosco, University of Connecticut School of Pharmacy, Connecticut; **Email:** elliott.bosco@uconn.edu

Additional Author (s):
Deborah Shelton

Purpose: Over 600,000 inmates are released to the community on an annual basis. Approximately 45% of federal and 56% of state inmates have a mental illness; of these, 40% have a co-occurring chronic illness. Treatment commonly consists of medication therapy, however, lack of adherence results in increased mortality risk and drives health costs. Upon release, inmates are challenged with maintaining adherence while establishing a new care team and facilitating insurance change. Limited research exists on pharmacists' ability to directly address inmate medication adherence. Thus, this study explores inmate perception of medication adherence and management as part of their treatment plan.

Methods: The institutional review board approved this cross-sectional qualitative study. Informed consent for semi-structured interviews was obtained from inmates meeting the following criteria: age 18 or older, receiving treatment for a chronic illness, English speaking, and incarcerated for at least 6 months in a prison or retained in a halfway house. Chronic illnesses included: depression, bipolar disorder, schizophrenia, substance abuse, hypertension, diabetes mellitus, and HIV/AIDS. Illnesses were divided into a physical illness group (hypertension, diabetes mellitus, HIV/AIDS) and a mental illness group (depression, bipolar disorder, schizophrenia, substance abuse). Inmates self-reported their adherence status. Recruitment was facilitated through posted fliers with inmates self-requesting to participate. Interviews were conducted by trained research assistants, audio recorded for transcription, and analyzed using NVivo 11 Pro. Four study questions were selected for thematic analysis: 1) Do you take your medications as prescribed, and why? 2) How do you feel about taking medication for your illness? 3) Are you experiencing any problems or side effects due to your medications and how do you handle this? and 4) Have there been any changes to your medications and how

was this process handled? Responses to each question were coded and reviewed by a second researcher to identify common themes.

Results: All interviews were conducted between January and December 2015. Interviews were conducted with 23 male inmates (n= 7 in prison; n=16 in halfway houses) until saturation was reached. A total of 6 inmates reported non-adherence, 17 reported adherence, 7 had a physical illness, and 16 had a mental illness. For the physical illness group, 1 was non-adherent and 6 were adherent. Among the mental illness group, 5 were non-adherent and 11 were adherent. A total of 16 different themes for the four questions were identified, including: Momentary Disruptions, Timeliness, Personal Beliefs, Patient Education, Tangible Benefits, Potential Risks, Acute Relief, Counseling, Loss of Faith, Lack of Need, Cognitive Side Effects, Therapy-limiting Side Effects, Physical Side Effects, Unmatched Expectations, Limited Provider Access, and Data Use. Patient Education was the only theme identified in multiple questions. Extrapyramidal symptoms (EPS) and weight gain presented as common reasons for medication change among inmates located in prison. On transition to halfway houses, inmates often demonstrated a lack of awareness for available community health resources.

Conclusion: From a group of predominantly adherent mentally ill male inmates, identified themes suggest the benefit of patient education in both the inpatient correctional health setting and outpatient setting on inmates' transition to the community. From the inpatient setting, pharmacists are well suited to perform comprehensive medication therapy management for the psychiatric population. In an outpatient setting, the community pharmacist is poised to supply medication information and additional health guidance to inmates in transition. Overall, the pharmacist's adept medication knowledge and availability allow for medication management and support of inmate medication adherence.

Poster Title: Rates of urinary tract infections in renal transplant recipients receiving pentamidine versus sulfamethoxazole-trimethoprim for opportunistic infection prophylaxis

Primary Author: Taylor Harkness, University of Connecticut School of Pharmacy, Connecticut; **Email:** taylor.harkness@uconn.edu

Additional Author (s):
Elizabeth Cohen
David Reardon

Purpose: Due to their immunosuppressed state, patients post-renal transplantation should receive prophylaxis against opportunistic infections. Sulfamethoxazole-trimethoprim (SMZ/TMP) 400/80mg orally daily is commonly used to prevent Pneumocystis Jirovecii (PCP) infection as well as reduce the risk of urinary tract infections (UTI). Patients frequently require alternative therapy for many reasons including allergy, hyperkalemia, or drug induced thrombocytopenia. Aerosolized pentamidine 300mg monthly can be used as a prophylactic alternative to SMZ/TMP although it does not provide coverage for UTIs. The purpose of this analysis is to describe the rates of urinary tract infections in patients on pentamidine versus those taking SMZ/TMP.

Methods: A retrospective chart review was conducted on all patients that received a renal transplant during the time period of January 1 to December 31, 2015. Patients were included if they received SMZ/TMP or pentamidine for PCP prophylaxis and were followed for six months post-transplant, our centers duration for PCP prophylaxis. Patients were excluded if they received PCP prophylaxis with a different agent, had an incomplete medical record, or received a multi-organ transplant. The primary outcome assessed was the rate of urinary tract infections confirmed with a positive urine culture with bacterial growth greater than 100,000 colony forming units/mL. Secondary outcomes assessed included the rate of UTIs in all patients that received treatment for a UTI and rate of SMZ/TMP resistance in patients with culture confirmed urinary tract infections. Baseline patient characteristics were also collected and included gender, type of renal transplant, and induction agent.

Results: We screened 94 patients and excluded six patients who received dapsone as PCP prophylaxis. There were 25 patients included in the pentamidine group and 63 patients in the SMZ/TMP. Baseline characteristics were similar between groups. Patients receiving pentamidine experienced significantly more culture confirmed UTIs than patients receiving SMZ/TMP (28 percent versus 6.3 percent, P equals 0.01). The odds of patients experiencing a UTI in the pentamidine group were 5.7 times more likely to occur than those who received SMZ/TMP. The secondary outcome revealed that when treatment was included in the definition of a UTI 36 percent of patients in the pentamidine group experienced a UTI compared to 23.8 percent of patients in the SMZ/TMP group (P equals 0.250). Of the patients that experienced this secondary outcome, 80 percent of patients in the SMZ/TMP group were confirmed through receiving treatment while 22 percent of patients in the pentamidine groups were confirmed through treatment. Although not statistically significant, SMZ/TMP resistance was seen in all patients in the SMZ/TMP group compared to 42.9 percent of patients in the pentamidine group (P equals 0.138).

Conclusion: The use of pentamidine for opportunistic infection prophylaxis post-transplant resulted in more culture-confirmed urinary tract infections compared to patients who received SMZ/TMP. Patients on SMZ/TMP prophylaxis had a trend toward an increased rate of resistant UTIs.

Submission Type: Evaluative Study

Session-Board Number: 2-024

Poster Title: Analysis of empiric cefepime utilization and de-escalation practices at UConn Health John Dempsey Hospital

Primary Author: Michael Duprey, University of Connecticut School of Pharmacy, Connecticut; **Email:** mike.duprey1@yahoo.com

Additional Author (s):
Mark Wysocki
Jeffrey Aeschlimann

Purpose: Excessive use of broad spectrum antibiotics such as cefepime increases the risk of developing antibiotic-resistant infections and can increase risk for Clostridium difficile infections. While cefepime can be appropriate for the empiric therapy of many healthcare-associated infections, recent nationwide shortages have made ensuring its judicious use even more critical. The purpose of this study was to assess the current empiric utilization and de-escalation practices for cefepime in a 174-bed suburban teaching hospital with an active antimicrobial stewardship program. Particular attention was devoted to identifying factors such as allergy history and culture results and their possible impacts on subsequent de-escalation practices.

Methods: This was an institutional review board-approved retrospective evaluation of all patients who received intravenous cefepime for at least 48 hours between the months of March and May 2016. Electronic medical records were evaluated to examine whether cefepime therapy was de-escalated at any point and what antibiotics (if any) were used during de-escalation. De-escalation was defined as (1) discontinuation of the initial empiric cefepime regimen or (2) changing to a more narrow spectrum antibiotic with or without supporting culture data. Maintenance on cefepime or a switch to another broad-spectrum agent was deemed clinically appropriate if the pathogen(s) that grew from cultures had no obvious antibiotic de-escalation options (e.g., Pseudomonas aeruginosa). For each patient we also analyzed: concomitant antibiotic use with empiric cefepime, the frequency of obtaining cultures before the first antibiotic dose, types of cultures obtained, frequency of positive culture results, and antibiotic susceptibility patterns.

Results: Seventy-five cefepime courses were included in the data analysis. Median and mean (standard deviation) durations of cefepime therapy were 4 and 4.8 (2.3) days, respectively. Concomitant antibiotics were initiated with cefepime 84 percent of the time; vancomycin was utilized most often (76 percent). De-escalation occurred in 59 of 75 cases (79 percent). Thirteen patients (17 percent) had an allergy to at least one other class of antibiotic, which limited de-escalation possibilities. The mean duration of cefepime therapy was significantly shorter when de-escalation occurred versus when it did not occur (4.2 versus 6.9 days, $P < 0.05$). Cultures were obtained in 97 percent of cases (n=73); 91 percent (n=68) of the time, they were collected before antimicrobial therapy initiation. Blood cultures were most common (done in 84 percent (n=63) of cases prior to antibiotic administration). Only 41 percent (n=31) of cases had a culture specimen grow an identifiable pathogen. The most common sources of positive cultures were urine (n=10) and blood (n=9). De-escalation occurred at approximately the same frequency independent of culture results (81 percent of cases with positive cultures and 79 percent with negative cultures).

Conclusion: Nearly all cultures were taken before the first dose of antibiotics. Despite the high rates of specimen cultures being performed, less than half resulted in positive identification of a pathogen. However, de-escalation still occurred at reasonably high frequencies in patients regardless of whether the cultures were positive or negative. The presence of antibiotic allergies listed in the patient medical record appeared to be a possible factor that limited de-escalation.

Session-Board Number: 2-025

Poster Title: Enhancing Self-Management of Diabetes Mellitus in a Geriatric Population using a Peer Group Structure

Primary Author: Stacie Noreika, University of Connecticut School of Pharmacy, Connecticut; **Email:** stacie.noreika@uconn.edu

Purpose: Current literature suggests a modest but significant long-term improvement of glycemic control with long-term education in geriatric patients with type 2 diabetes mellitus (T2DM). Short-term education, defined as less than six months, has positive effects on glycemic control, but the long-term impacts of this short-term education remain unclear. This study aims to determine if self-management education delivered through a peer group structure provides adequate intervention to improve diabetes self-management in a geriatric population.

Methods: The University of Connecticut's institutional Review Board approved this pilot research program. After screening for eligibility and providing informed consent, participants aged 65 years and older with T2DM were enrolled in a diabetes self-management education program at the Mansfield, CT Senior Center. The program consisted of 5- 75 minute sessions, one session every other week spanning September 2015 through November 2015 and a 6 month follow up session in May 2016. The program's sessions consisted of a survey, short presentation on the day's topic, and group discussion facilitated by a pharmacy student and pharmacist. The topics were Introduction and Overview; Lifestyle; Medication Management; Nutrition; Appointments, Checkups, and Debrief; and Follow Up. Surveys were used to gauge baseline and final participant knowledge and attitudes about various aspects of T2DM management. Patient reported adherence to any lifestyle changes, including medication adherence, via surveys at the first, last, and 6 month follow up session. Patient-reported hemoglobin A1C (A1c) and/or fasting blood glucose data were collected to determine if there were any indications of a positive clinical effect resulting from attendance at such a program.

Results: Pre-program 5-item survey indicated that 60% of participants self-reported "fair" control of their diabetes and 40% self-reported "average" control. At the last session, 80% reported "very good" control and 20% reported "average" control. Markers of change in self-management, including blood glucose and blood pressure monitoring, engagement in exercise,

and medication adherence saw improvements as well. In participants where pre- and post- A1C and fasting glucose values were available, average pre-program values were 7.5% and 121mg/dL, respectively. Post-program, the values decrease to 7.0% and 112mg/dL, respectively. Patient satisfaction with the program was rated on average a 9 on 10 (best)-point scale.

Conclusion: A peer group structure can be an effective delivery method for engagement in diabetes self-management. Participants' self-reported medication adherence, blood glucose and blood pressure monitoring, and exercise increased. Participants expressed desire to have more sessions focused on diabetes medications. The results of this pilot program are promising, but clinical significance must be determined in trials in which results are not only patient-reported.

Poster Title: Pharmacy students' leadership of community outreach initiatives in the University of Connecticut's interprofessional Urban Service Track curriculum

Primary Author: Lauren Sullivan, University of Connecticut School of Pharmacy, Connecticut; **Email:** lauren.sullivan@uconn.edu

Additional Author (s):
Nadya Peresleni
Devra Dang

Purpose: The Urban Service Track (UST) is a unique interprofessional curriculum among six health profession programs (dental medicine, medicine, nursing, pharmacy, physician assistant, and social work) designed to teach students about caring for urban underserved populations. Two core components of the curriculum involve engaging in community outreach projects and the development of team leadership skills. When the curriculum was initially established, the community outreach projects were developed by faculty members. With time, however, pharmacy students also took on the leadership of creating and implementing a variety of outreach projects to help expand the program's impact on underserved communities throughout Connecticut.

Methods: Each year, pharmacy UST students identified vulnerable patient populations not addressed by existing UST community outreach programs. These projects were designed to meet specific healthcare needs unique to target populations, including seniors, smokers, children, the uninsured, first generation immigrants, and populations that are not typically present at existing UST health fairs and other health education and screening events. These pharmacy-led outreach programs established a focus on medication education topics. Pharmacy UST students worked with the pharmacy faculty director to identify relevant topics and populations and design methods to effectively deliver the health information. All health education activities were designed to be interactive in order to actively engage community members. Leadership skills were also developed through the process of collaborating with community partners and coordinating events with healthcare students from six health professions at different education levels. For each project, the pharmacy team leaders designed training programs for student team members (clinical skills primers) so that all are comfortable

with not only the health education topic being presented but also how to provide the information in a health-literacy and culturally-appropriate manner.

Results: UST pharmacy students have developed seven outreach projects over the last five years. The Affording Medications Project provides community members with resources and individualized education on how to decrease the cost of medications. From Wheeze to Breeze is an interactive program that provides information on the pathophysiology and treatment of asthma and chronic obstructive pulmonary disease, with a focus on medications and proper inhaler technique. The Going Beyond Initiative organizes health education presentations for underserved communities not otherwise reached by other UST events. The Immunization Awareness project is designed to not only provide information about the recommended vaccine schedule for adults but also to dispel common myths about immunizations. The Tick-Borne Illness Prevention: Aware and Prepared program focuses on providing practical advice on preventing Lyme disease and other tick-borne conditions with a high prevalence in Connecticut. No Ifs Ands Or Butts is a two-fold project that focuses on smoking cessation in adults and smoking prevention education in children and youths. Lastly, Spring Forward-Don't Fall Back is an interactive program that educates seniors on important fall prevention strategies. Although all are led by pharmacy students, each program incorporates interprofessional teams of students from the six health profession schools.

Conclusion: By maintaining such active involvement in the Urban Service Track's community outreach curriculum, University of Connecticut pharmacy students have emerged as successful leaders in healthcare education to underserved populations throughout Connecticut. New pharmacy-initiated projects continue to emerge each year, providing increasing opportunities for pharmacy students to develop as future professionals who will be active leaders on interprofessional healthcare teams.

Poster Title: Evaluation of a pharmacist-driven therapeutic substitution program for cefepime dosing based on renal function and indication for inpatients at UConn John Dempsey Hospital

Primary Author: Adam Krakowiak, University of Connecticut School of Pharmacy, Connecticut;
Email: adam.krakowiak@uconn.edu

Additional Author (s):
Jeffrey Aeschlimann

Purpose: Antimicrobial stewardship programs seek to minimize incidences of unnecessary or suboptimal antibiotic use. This involves conducting activities including the utilization of patient factors to optimize drug concentrations and minimize adverse effects. In 2015, UConn John Dempsey Hospital implemented a P&T-approved Therapeutic Substitution program where physicians select an initial order for cefepime based on presumed infection and estimated renal function, and then pharmacists automatically adjust the dose and interval from their assessment of those parameters. The goal of this current investigation was to identify if the program yielded any improvements in appropriately administering cefepime for our patients.

Methods: This was an institutional review board-approved retrospective chart review that analyzed 100 inpatients at UConn John Dempsey Hospital. We compared 50 patients who received cefepime from May to July of 2015 (before the dose-adjustment program) with 50 patients who received cefepime in March and April of 2016 (after the program started). We evaluated the initial dosing regimen of Cefepime that patients received and determined the appropriateness by calculating initial renal function and determining the chart-documented clinical indication(s) for use. We performed these analyses for any subsequent changes in the cefepime regimen during each patient's complete course of therapy. We also assessed each patient's renal function for each day of cefepime therapy to determine if interval adjustments were necessary (and if these changes were implemented by the pharmacists). Creatinine clearance was estimated using the Cockcroft-Gault equation with adjustments for obesity as appropriate. We also evaluated the mean duration of therapy for cefepime, the frequency of dose adjustments, the number of occurrences of suboptimal dosing, and the duration that suboptimal dosing persisted. Statistical analyses were conducted using Ministat and SPSS statistical software.

Results: Sepsis was the most common indication for cefepime use (n=16 in the post-dose adjustment group, n=10 in the pre-dose adjustment group). The mean initial creatinine clearance (CrCl) was 63.6 mL/min in the post-dose adjustment program group and 67.7 mL/min pre-dose adjustment program group. The number of patients with a correct initial cefepime dosing regimen was comparable (n=16 in both groups) and the numbers that received correct subsequent doses (after dosing changes) remained comparable. For the patients who had any errors in dosing according to the protocol guidelines, the mean (SD) duration of the incorrect dose was approximately 1 day shorter in the post-dose adjustment program group as compared to the pre-dose adjustment program group (3.1 versus 3.9 days). This difference approached statistical significance (P=0.1). The overall duration of cefepime therapy was significantly shorter in the post-dose adjustment program group as compared to the pre-dose adjustment program group (3.3 versus 5.2 days, P=0.001); this was likely related to concomitant implementation of more active streamlining efforts of the antimicrobial stewardship program in 2016.

Conclusion: The implementation of a pharmacist-driven therapeutic-substitution program for cefepime did not appear to increase the prevalence of initially-appropriate regimens of cefepime. However, patients who have received cefepime after program implementation may have a shorter duration of improper dosing when it occurs. With continued larger sample-size analyses of this newly-approved program, we hope to document the occurrence of further optimized usage of cefepime.

Session-Board Number: 2-028

Poster Title: Foreign observer program development at a large health system

Primary Author: Xiaowei Wang, University of Connecticut, School of Pharmacy, Connecticut;
Email: shirlyw040192cn@gmail.com

Additional Author (s):
Amber Castle

Purpose: Foreign exchange programs are mutually beneficial to both the hosting institution and the observer. Due to an increased demand for these experiences, a need to formalize the process was identified. The purpose of this study was to develop a standardized procedure to support foreign observer rotations in pharmacy at Yale New Haven Health System (YNHHS). Specific aims of this project were to address logistical, administrative, legal and cultural barriers to hosting foreign observers.

Methods: Requests for rotations for foreign observers (students or practicing pharmacists from outside of the United States) raise unique concerns, especially the requests that are not facilitated under an existing university affiliation agreement. These observers are not licensed to provide direct patient care and are not typically covered underneath the hospital health or liability insurance. Due to cultural differences and limited local social support, these observers often require more extracurricular assistance.
Our study is the first description of a standardized process for inpatient pharmacy experiences. A foreign observer standard operating procedure (SOP) was developed in collaboration with human resources, volunteer services, risk management, experiential education staff, and the pharmacy department at YNHHS to facilitate successful foreign observer rotations. Candidate eligibility was defined based upon U.S. Department of State Exchange Visitor Program regulations (22 CFR Part 62), required documentation was identified, and a scaled fee structure was developed based on World Bank Country Classification. An application timeline was delineated. A cost analysis was performed examining program costs and revenue.

Results: In the SOP, candidates are provided with an application toolkit including eligibility criteria, required documents, and the approval process. Once a candidate is accepted, the program provides an official letter describing the rotation purpose, dates and hours, as well as a

paper-based site orientation. Observers must provide a letter of recommendation, evidence of health insurance, vaccine records, tuition fee, rotation preferences, and emergency contact information to the program.

Cultural barriers could exist in curricular and extracurricular activities. The program should be prepared to give instructions on professional demeanor, including dress code and punctuality. A student ambassador preferably with relevant language proficiency is identified who assists the observers acclimate to the local culture.

The application timeline is determined considering the deadline for application materials, observer's date of arrival in the United States, and the start date of program. Additional time may be needed to secure housing, travel, and visa.

From 2014 to 2016, the program has expanded from two to seven observers from a total of five different countries (Brazil, China, Jordan, Philippines, and Spain) with a corresponding revenue increase. Rotations range in duration from two weeks to five months with the implementation of a longitudinal rotation option in 2016.

Conclusion: Expansion of foreign observer rotations is desirable to promote the development of clinical pharmacy services globally, and to support mutual growth and professional development of observers and their preceptors. Logistical, administrative, cultural and legal issues must be addressed when considering hosting foreign observers. This study presents a program that can be used as a model for other institutions who would like to offer this educational service.

Poster Title: The diagnostic value of procalcitonin in predicting urinary tract infections among adult patients who present to the emergency department

Primary Author: Midori Tran, University of Saint Joseph School of Pharmacy, Connecticut; **Email:** mtran@usj.edu

Additional Author (s):
Dora Wiskirchen
Evan Nadler
Edgar Naut
Alexander Levine

Purpose: Urinary tract infections (UTIs) are one of the most common infections encountered in the emergency department. Clinicians must rely on subjective signs and symptoms combined with urinalysis results to make the decision to initiate empiric antibiotics. However, clinical presentation and typical laboratory values are often non-specific for the presence of a bacterial infection. Procalcitonin (PCT) has emerged as a reliable biomarker for detecting bacterial infections and is readily available in the emergency department to guide UTI treatment decisions. The purpose of this study is to investigate the diagnostic value of PCT to determine the likelihood of UTI in adult patients.

Methods: A retrospective study of patients who presented to the emergency department at Saint Francis Hospital and Medical Center (SFHMC) between December 2015 and May 2016. The study was approved by the Institutional Review Board. Patients were eligible for the analysis if they were 18 years or older and presented with the following: at least 1 sign and symptom of UTI (dysuria, hematuria, frequency, urgency, suprapubic pain, confusion, flank pain, temperature greater than 100.4ºF or chills); plus a positive urinalysis and culture or positive blood culture with known uropathogen and a PCT level drawn within 24 hours of initial presentation. Patients were excluded for any of the following: primary infection other than UTI, renal replacement therapy, history of thyroid disorder, kidney transplant, or spinal cord injury. SFHMC's criteria for positive urinalysis to reflex to urine culture is greater than or equal to small leukocyte esterase, moderate occult blood, 6 WBCs, or 4 RBCs; positive for nitrates; or bacteria

present. Sensitivity, specificity, positive, and negative predictive values were calculated for PCT using a threshold greater than or equal to 0.5 µg/L.

Results: 91 patients were evaluated during this time period. Seventy-one patients met inclusion criteria with 43 patients having a PCT level greater than or equal to 0.5 µg/L and 28 with a PCT level less than 0.5 µg/L. Seventy-four percent of patients (32/43) with a PCT level greater than or equal to 0.5 µg/L and 43 percent of patients (12/28) with PCT levels less than 0.5 µg/L had a positive diagnosis of UTI, respectively. The sensitivity and specificity of PCT to predict a positive UTI diagnosis using a threshold level of greater than or equal to 0.5 µg/L and less than 0.5 µg/L were 73% and 59%, respectively. The corresponding positive and negative predictive values were 74% and 57%, respectively.

Conclusion: A PCT threshold greater than or equal to 0.5 µg/L is moderately sensitive and specific at detecting a positive UTI. PCT levels that reach at least 0.5 µg/L within 24 hours of patients' initial presentation may aid clinicians in determining the likelihood of a positive UTI diagnosis during their hospital course. Therefore, elevated PCT levels used in conjunction with other clinical signs and laboratory values may guide appropriate empiric antibiotic use.

Poster Title: Evaluation of novel enaminones as potential anticonvulsant agents

Primary Author: Iregi Francis, University of Saint Joseph School of Pharmacy, Connecticut;
Email: ifrancis@usj.edu

Additional Author (s):
Emma Gimose
Peter Okwesili
Atem Atembe
Ivan Edafiogho

Purpose: Epilepsy affects a significant number of people worldwide. Anti-epileptic drugs (AEDs) currently in use have significant adverse effects and pharmacodynamic-pharmacokinetic interactions. Thus, there is a need for new anticonvulsant compounds with fewer adverse effects and a wider scope of activity. Enaminones are chemical compounds consisting of an amino group linked through a C=C bond to a keto group and dibromophenyl enaminones make the halogenated enaminone series. The purpose of this project was to synthesize dibromophenyl enaminones and evaluate them for in vitro anticonvulsant activity.

Methods: Three independent routes of synthesis were followed in preparing the beta-hydroxyketo starting material to maximize the yield. The alkyl acrylate (A) was reacted with alkyl acetoacetate (B) in the presence of sodium alkoxide. An acid-base extraction with dichloromethane afforded the tautomers (C) and (D). The tautomer (C) was predominant because stabilization was increased by intermolecular and intramolecular hydrogen bonding. The second synthetic route involved the reaction of an alkylidene ketone (E) with dialkyl malonate (F) in sodium alkoxide to give compounds (C) and (D). The third route involved the reaction of compound (E) and (F) in the presence of potassium carbonate to give the adduct (G) which was cyclized in the presence of sodium alkoxide to compounds (C) and (D). Condensation of the beta-hydroxyketo esters (C) and (D) with 2, 4-dibromoanilines yielded the corresponding enaminones of type (H). UV, IR, NMR, mass spectra and elemental analysis (CHN) confirmed the structures of the dibromophenyl enaminones The dibromophenyl enaminones compounds coded AK1, AK2, AK6, AK7, FA1, FA2, FA4 and E249 were then evaluated for activity on population response in the cell body layer of the Cornu Ammonis 1 (CA1) area of a rat's

hippocampus by recording population spikes in current clamp mode. The effectiveness of these compounds was judged on how much they were able to decrease evoked population spike amplitudes (PSAs) in CA1.

Results: Eight dibromophenyl enaminone analogs were synthesized and fully characterized. Six of the compounds (AK6, E249, FA1, AK7, AK1, and AK2) were anticonvulsant in vitro and they all suppressed PSA in a concentration dependent manner. Two dibromophenyl enaminones (FA2, and FA4) demonstrated pro-convulsant activity. AK6 and E249 had EC50 of 2.1 and 1.9 micromoles respectively. At a 10 micromolar concentration, AK6 and E249 were more efficacious compounds with a PSA depression of 72 percent and 35 percent respectively. FA1, AK7, and AK1 caused 25 percent, 24 percent, and 18 percent PSA depression respectively.

Conclusion: The dibromophenyl enaminones analogs represented a series of novel enaminones that predominantly had anticonvulsant in vitro. In the in vitro evaluations, the most potent anticonvulsant enaminones were AK6 and E249. They were considered desirable lead compounds in the novel enaminone series. Overall, the dibromophenyl enaminones demonstrated potent anticonvulsant activity and are thus promising novel anticonvulsant agents. Further in vivo evaluation has been arranged to be done by the Epilepsy Therapy Screening Program (ETSP) of the National Institute of Health (NIH).

Poster Title: Evaluation of naloxone availability and prescribing habits in primary care and community pharmacies in the Greater New Haven area

Primary Author: Kaitlyn Ross, University of Saint Joseph School of Pharmacy, Connecticut; **Email:** klross@usj.edu

Additional Author (s):
William Bruneau
Tamara Malm
Benjamin Howell

Purpose: The rate of opioid-related overdoses in the United States has quadrupled since 2000, where half of overdoses are due to prescription opioids. Connecticut legislation has recently changed to allow naloxone, a pure opioid antagonist, to be prescribed by certified pharmacists. Naloxone is indicated for the reversal of life-threatening opioid induced central nervous system and respiratory depression. The aim of this study is to assess the rate of naloxone prescribing and the availability of naloxone at community pharmacies in the Greater New Haven community. This study was approved by the Yale University IRB.

Methods: Data assessing the rate of naloxone prescribing was collected via retrospective chart review of adult primary care patients at Yale-New Haven Hospital, Saint Raphael Campus, with a prescription for any opioid in the last 12 months. Prescriptions for codeine, fentanyl, hydrocodone, hydromorphone, methadone, morphine, oxycodone, buprenorphine, tapentadol, and oxymorphone were included. The total daily morphine equivalent (MEQ) was calculated using the maximum strength and quantity prescribed in a 24-hour period. Naloxone prescriptions were considered current if prescribed in the last 12 months.
The availability of naloxone was collected via telephone survey of all community pharmacies in New Haven, Hamden, East Haven, and West Haven. After receiving verbal consent, an eight-item survey was used by researchers to collect rates of and barriers to prescribing, dispensing and stocking rates of naloxone in pharmacies.
All data was analyzed in Excel using means for continuous outcomes and frequency for categorical outcomes.

Results: A total of 367 patients had at least one opioid prescribed within the previous 12 months. Daily MEQ ranged from 1.5 to 1440 (average 129.1), where 179 patients (48.7 percent) had greater than 50 MEQ prescribed per day and 121 patients (32.9 percent) had greater than 100 MEQ prescribed per day. Naloxone prescriptions were current for eight patients (2.2 percent), who had daily MEQ ranging from 180 to 480 per day (average 292.2).
A total of 55 pharmacies were identified for survey in the Greater New Haven area, of which 46 (84 percent) offered verbal consent to participate. Certified pharmacists were available to prescribe naloxone in 26 pharmacies (56 percent), with seven pharmacists reporting having written a naloxone prescription in the last week. The most common pharmacist barriers to prescribing included lack of patient demand, lack of training in the different products and a lack of protocol for prescribing. Naloxone was stocked in 34 pharmacies (74 percent), where pharmacists reported no barriers to stocking the product.

Conclusion: Opioid-related deaths are preventable, and the increasing prevalence of opioid abuse shows the need for greater access to naloxone. The rate of naloxone prescribing at this Adult Primary Care Center, in combination with the rate of community pharmacist prescribing shows that patient access is still a concern. Despite legislative efforts to increase use of the product in Connecticut, education for physicians, pharmacists and patients is still needed. The findings related to naloxone access outlined in this study will be used to guide subsequent local interventions targeted at the identified barriers.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Descriptive Report

Poster Title: Minority inclusion in 2015 new molecular entities (NMEs) approved for psychiatric disorders

Primary Author: Reena Thomas, Florida A & M University, Florida; **Email:** reena.thomas.famu@gmail.com

Purpose: In this research study, it is important to analyze the safety and efficacy for psychiatric disorders based on race and ethnicity. Focusing on the demographic subpopulations in pivotal trials for Aristada (Aripiprazole Lauroxil), Rexulti (Brexpiprazole), and Vraylar (Cariprazine HCl), helped determine the safety and efficacy of these medications. This project was designed to show healthcare providers how these medications can be prescribed based on these factors.

Methods: According to the Food and Drug Administration, studies were shown on how it affects the patients quality of life. The center for drug evaluation and research included medication guides, summary reviews, medical reviews, pharmacology reviews, clinical pharmacology biopharmaceutics review and statistical reviews for the listed psychiatric medications. The safety analysis for Rexulti (Brexpiprazole) states in the major depressive disorder program, demographic characteristics for United States and non-United States subjects were similar, with the exceptions of race (almost 100 percent of subjects were white at non-US sites compared with approximately 78 percent at US sites) and body mass index with similar findings for associated characteristics. The efficacy analysis for Rexulti (Brexpiprazole) states subgroup analyses were conducted based on demographic characteristics (sex, race, age, and region of origin) and based on degree of improvement during Phase A (less than 25 percent improvement and greater than 25 percent improvement). Due to the scientific studies, the population was focused on administering these medications to the psychiatric patients.The inclusion factor of this experiment is that these patients must be living with these psychiatric disorders.

Results: No significant subgroup differences were identified in the analysis of race and ethnicity for Aristada (Aripiprazole Lauroxil), Rexulti (Brexpiprazole), and Vraylar (Cariprazine HCl). In Africa, lower CYP2D6 activity in relation to genotype was found, indicating that environmental factors (infections or food constituents) are probably of importance in addition to genetic factors. Studies conducted within or outside the United States should consider the potential

contribution of genotype to drug metabolism or transport pathway, since metabolism of CYP2D6 substrates are poor in approximately 8 percent of Caucasians and 3 to 8 percent of African Americans. The United States National Comorbidity Survey Replication (NCS-R) study reported the prevalence of schizophrenia among African Americans, Hispanics, and Non-Hispanic Whites are similar. There was an increased rate of schizophrenia diagnosis for African Americans compared to Caucasians, ranging from 9 to 32 percent. Whites were more likely to be diagnosed with major depressive disorder (MDD) and bipolar disorder (BD) compared to African Americans, ranging from 7 to 33 percent. While African Americans are less likely than Caucasians to be diagnosed with major depressive disorder (MDD), when they do, it tends to be more chronic and severe.

Conclusion: The medical reviews did not have sufficient information pertaining to the safety and efficacy for the minorities. Based on clinical studies, there is an increase in efficacy for the atypical antipsychotics in African Americans compared to the other medications.

Submission Type: Descriptive Report

Session-Board Number: 2-033

Poster Title: Examining the current impact, barriers, and roles pharmacists have in the management of chronic diseases

Primary Author: Margareth Larose, Florida A & M University, Florida; **Email:** margareth.larose@famu.edu

Additional Author (s):
Jordan Carroll
Ana Chavis
Naomi Chiti

Purpose: The purpose of this study was to assess the views of Florida pharmacists on the impact, barriers and roles they currently have in the management of chronic disease states such as diabetes, hypertension, hyperlipidemia, and chronic kidney disease.

Methods: Florida pharmacists were provided a survey either electronically or in-person. The survey assessed the pharmacist's views on the impact and roles they have and the barriers that they currently face in managing and monitoring chronic conditions. The study took place over a period of three months and the data was collected and analyzed utilizing survey monkey.

Results: Sixty one pharmacists completed the survey. Fifty percent (thirty-one) of the pharmacists that completed the survey practice in a retail or community setting. The most frequent disease state seen was diabetes at ninety-one percent (fifty-five). On average, fifty-nine percent (thirty-three) of the pharmacists encourage lifestyle modifications and contact prescribers for patients. These are the top two roles pharmacists have in the management of diabetes, hypertension, hyperlipidemia, and kidney disease. Thirty-six percent (twenty-two) pharmacists felt comfortable in managing these disease states, and thirty-one percent (nineteen) felt slightly comfortable. Sixty-six percent (forty) of the pharmacists revealed that time constraints was as a challenge. Hence, fifty percent (twenty-nine) pharmacists deem that more time will improve their roles in managing the disease states, and forty-four percent (twenty-seven) viewed their current role as being slightly effective. Despite the barriers faced by pharmacists, fifty-three percent (thirty-one) anticipate that their role will increase in managing and monitoring patients with hypertension, diabetes, chronic kidney disease, and

hyperlipidemia. Moreover, all survey participants agree that additional training in pharmacy school and continuing education, more time dedicated to patients, and support form employers will result in an increase in the pharmacists role in managing and monitoring patients with these disease states.

Conclusion: The results of this survey support existing literature and also emphasize the pivotal role that pharmacists must play in chronic disease management. The study was limited because it could not quantify the impact pharmacists have from the role they currently play. Pharmacists can do more to improve patient care outcomes but they need to be provided the opportunity, continuing education and training, and adequate time to efficiently utilize their qualifications to help improve the quality of life for those patients with chronic diseases.

Submission Category: Ambulatory Care

Submission Type: Evaluative Study

Session-Board Number: 2-034

Poster Title: Provider gender preference: A patient centered approach

Primary Author: Tristan Collum, Florida A&M University, Florida; **Email:** tristan.collum@gmail.com

Additional Author (s):
Jaria Butler
Allison Ringo
Lillian Smith-Mosley
Juan Mosley

Purpose: Provider gender preference for medical care and treatment influences many aspects of patient care in the healthcare system. The primary outcome of this study is to determine whether the gender of a physician influences a patient's decision when selecting a provider for medical services. Psychological factors such as sexism, past experiences, and trauma may be aspects that persuade the decision making process. Secondary outcomes will consist of the more preferred gender of physicians among patients and the most common influential psychological factors.

Methods: This study was approved by the Florida Agricultural and Mechanical University Institutional Review Board. Individuals 18 years of age and older living in the United States are eligible to participate in the survey. Prior to completing the survey, informed consent was obtained. Participants will receive surveys that will allow them to respond anonymously either in person (hard copy) or via emails (electronic copy). Surveys will be composed of various structured questions, measured using a Likert Response Scale or free response, to assess each individual's opinion. The survey will encompass a wide variety of questions in order to accurately assess the patients view on this matter. Once surveys are completed, hard copies will be immediately collected by research personnel and electronic copies will be stored utilizing Survey Monkey software. The answers from the surveys will be tallied and analyzed in order to determine if physician gender plays a role in choosing a healthcare provider. Responses to the survey are entirely optional and participants will not receive any compensation. Those excluded from the study include patients less than the age of 18 and individuals with limitations in health literacy or cognitive dysfunction. The data collection

process is expected to take place over a period of 3 months, at which time results will be collected to determine the stated objectives.

Results: Results are currently pending, however we hope to determine an age range and specified genders of participants currently seeking healthcare. Data analyzation will aid in the process of determining the primary and secondary endpoints. We also hope to determine if gender preference truly influences medical care and if psychological factors influence the decision making process. The results will bring awareness to the issue of provider gender being a preference among our current patient population.

Conclusion: While our conclusion is currently pending, we anticipate that gender does play a role in determining which provider is selected due to individual participant comfortability and psychological factors.

Poster Title: Do the ads add up: patient perceptions of medication advertisements

Primary Author: Alex Jackson, Florida Agricultural and Mechanical University, Florida; **Email:** abjackson1103@gmail.com

Additional Author (s):
Ashley Hargrett
Melanie Kriser
Juan Mosley

Purpose: The purpose of this study is to evaluate patient's perceptions of direct to consumer (social media, television commercials, magazines, etc.) advertised medications. The study seeks to assess how often participants are exposed to medication advertisements (over-the-counter, prescription, herbal supplements, etc.) as well as their perception of benefits, risks, indicated use, affordability and willingness to use of advertised medication benefits.

Methods: Upon approval of the investigational review board of Florida A&M University (IRB), investigators will solicit eligible research participants who are > 18 years of age. This confidential survey will encompass a variety of questions to assess participant's point of view of mediation advertisements. Research investigators will randomly solicit eligible participants to complete the survey through electronic means (email and social media) by attaching the survey monkey link. In addition, research investigators will pass out hard copy surveys to eligible participants to complete as well. By choosing to complete the survey participants will be providing implied consent. Those who complete a hard copy survey will retain the printed copy of the informed consent letter. Those who complete an electronic copy of the survey will have the option to print a copy of the informed consent letter. Over a 90-day data collection period we hope to obtain data from 300 participants. If the intended number of participants is not reached by this period, we will extend the data collection period for two additional weeks in order to obtain more participation. At the conclusion of the data collection period all hard copy survey data will be inputted into SurveyMonkey® for complete data analyzation. Data will then be compiled, analyzed, and developed into a poster presentation and manuscript to be presented at a professional conference and submitted for publication.

Results: Results for this research are currently pending, however We predict that participants will find medication advertisements lacking appropriate patient education, and participants will likely assume advertisements raise up medication costs. advertisements.

Conclusion: A conclusion will be formulated upon analysis of the results from the study.

Poster Title: Modern day students: A correlation between sleep habits and academic performance

Primary Author: Patsy Brantley, Florida Agricultural and Mechanical University, Florida; **Email:** patricia1.brantley@famu.edu

Additional Author (s):
Juan Mosley
Dustin Locke
Brandon Massengill
Shakorah Young

Purpose: The purpose of this research is to evaluate sleep habits among currently enrolled college students, and to determine if there is a correlation between sleep habits and their effect on classroom performance in these students.

Methods: Current Florida A&M University students who are over the age of 18, will be allowed to participate in the survey provided by the research investigators. Participants will be giving implied consent by choosing to complete the research survey, and will retain a copy of the informed consent letter for their records. The study will not include any participant identifiable information. This survey will encompass questions to assess the students' sleep habits and academic performance (such as naps, study habits, procrastination, and GPA). This survey will be sent to college students at Florida A&M University who are over the age of 18 and considered full time students. Full time for fall and spring semesters includes students taking 12 or more credit hours for undergraduate, and 9 or more credit hours for graduate students. Full time for summer includes students taking 9 or more credit hours for undergraduate, and 6 or more credit hours for graduate students. We will distribute surveys on campus and send out a link to the online survey via social media sites and emails. Our goal is to obtain 300 surveys to extrapolate data from. At the end of the research survey period, 90 days, collected data will be tallied, analyzed, and presented at a professional conference, after which, a manuscript will later be developed.

Results: Results are currently pending, however, a positive correlation is expected to be seen between healthy sleep habits and academic performance as supported by previous research.

Conclusion: A conclusion will be formulated upon analysis of the results from the study.

Poster Title: Evaluation of drug interaction alerts for QTc prolongation and the use of a risk score scale to predict the likelihood of QTc prolongation occurrences.

Primary Author: Roberto Larios, Florida Agricultural and Mechanical University, Florida; **Email:** roberto1.larios@gmail.com

Additional Author (s):
Jarrett Johnson
Ira Schatten
Jon Francisco
Meagan Muse

Purpose: QTc prolongation is an adverse event in which pharmacists have to assess the risk factors and drug interactions during medication review and verification. As the number of medications and drug interactions that can contribute to QTc prolongation have increased, the need for a standardized approach to gauge the risk has become more important.

Methods: A retrospective review of 241 random patients who had a drug interaction alert for QTc prolongation between May and July 2016 was conducted to assess the presence of QTc prolongation during admission. Data was collected to assess medications and other contributing risk factors for patients with or without QTc prolongation. Additionally, a risk score tool was utilized to correlate and validate the appropriateness of the drug interaction alerts and assess the ability to predict QTc prolongation occurrences. The risk scores were then compared with additional criteria including the use of known high-risk QTc prolonging drugs, and a medical history significant for electrophysiology involvement.

Results: 241 patient profiles were assessed. 98 profiles were excluded due to an absence of a baseline ECG recording or if a follow up ECG recording was not obtained. Of the patients identified as low risk based on the risk score scale, 24/53(45 percent) experienced QTc prolongation. 49/64 (77 percent) of patients identified as moderate risk also experienced QTc prolongation. Of the 26 patients identified as having high risk, 25(96 percent) experienced QTc prolongation.

Conclusion: The risk score tool was able to accurately identify patients with a low, moderate, and high risk of developing QTc prolongation. Used in conjunction with alerts for drug interactions, the risk score tool may be a valuable tool to identify patients who may require further monitoring prior to the occurrence of QTc prolongation.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Evaluative Study

Session-Board Number: 2-038

Poster Title: Relationship between personality traits and stimulant usage at a Historically Black College of Pharmacy

Primary Author: Talya Shahid, Florida Agricultural and Mechanical University College of Pharmacy and Pharmaceutical Sciences, Florida; **Email:** talyashahid@yahoo.com

Additional Author (s):
Muhammad Khan
Sheena Grayson
Edem Ante
Imani Pelt

Purpose: The use of stimulants among college students has significantly increased over the years and continues to rise. Students use stimulants of various forms to stay vigilant, focus, or to improve academic performance among other reasons. Using stimulants in higher doses can be very concerning as it may lead to adverse effects such as increased heart rate, anxiety and insomnia. The aim of this study was conducted to correlate the Mini International Personality Item Pool Five Factor model personality scale with the use of caffeine, energy drinks, and prescription stimulants in pharmacy students at a Historically Black College of Pharmacy.

Methods: After receiving Institutional Review Board approval, convenience sampling was utilized in distributing the questionnaire to pharmacy students. Informed consent was deemed to be given by each student by participating in answering the questionnaire. The Mini International Personality Item Pool Five Factor model personality scale, which included the personality traits of extraversion, openness, agreeableness, neuroticism, and conscientiousness, were correlated with student use of energy drinks, caffeine, prescription stimulant usage, and academic success. Pearson correlation statistics were used to assess the data.

Results: A total of 251 surveys were collected. Among the 251 participants, 69 or 27.5 percent were male and 182 or 72.5 percent were female. The median age at the baseline was 23.2 years. The study generated results which statistically showed the correlations between each of the 5 personally traits and how each relates to various aspects of stimulant, caffeine, and

energy drink usage, at an Historically Black College of Pharmacy. Of the 251 participants, 16 had taken prescription stimulants, 153 had taken caffeine, and 119 had taken energy drinks. Seven or 43.8 percent of the 16 that had taken prescription stimulants concluded it increased their grade point average. Conscientiousness had the strongest correlation, with an increase in academic performance and grade point average. Extraversion had a strong correlation with taking energy drinks.

Conclusion: Based on the results of this study; conscientiousness had the strongest correlations with more factors than any of the five factor personality traits. Extraversion had a strong correlation with taking energy drinks. The study yielded results, which showed statistically significant correlations of each of the five personality traits tested; extraversion, openness, agreeableness, neuroticism, and conscientiousness with various aspects of stimulants, caffeine, and energy drinks used by pharmacy students at a Historically Black College of Pharmacy.

Submission Type: Evaluative Study

Session-Board Number: 2-039

Poster Title: "Evaluation of early ambulation and its impact on the use of opioids in inpatients status-post total hip or total knee arthroplasty"

Primary Author: Margareth Larose-Pierre, Florida Agricultural and Mechanical University

College of Pharmacy and Pharmaceutical Sciences, Florida; **Email:** mhc0813@gmail.com

Additional Author (s):
Melea Clark
Akash Pathak
Adriana Rich

Purpose: The purpose of this study is to evaluate the impact that early ambulation has opioid use and length of hospital stay after total knee arthroplasty (TKA) and total hip arthroplasty (THA). Our primary endpoint is to determine if early ambulation (1-24 hours post surgery) leads to decreased opioid use based on an average of morphine equivalents administered to the patient throughout their hospital stay.

Methods: A retrospective chart review was performed on all patients who underwent TKA or THA at a community not-forprofit hospital in Northwest Florida. A sample group of 150 patient charts were reviewed and data were collected on patient demographics, peri- and post-operative opiate use, surgical procedure, time of first ambulation, morphine equivalent administration, and length of hospital stay. The data were analyzed to determine the correlation between first time of ambulation performed by physiotherapists, the total amount of opioid use (calculated into morphine equivalent) and the length of hospital stay. The Student T-test will be performed to compare the group of patients who ambulated early (within 24 hours) versus patients who ambulated after 24 hours post-surgery and the amount of opiate administered in each group.

Results: A total of 50 patients charts were evaluated out of the 150 patient sample size. Thirty-eight patients (76 percent) were found to have started early ambulation therapy within an average of 12 hours post-operative ambulation. On average, these patients received 158mg of morphine from the time they were out of surgery until they were discharged from the hospital. The other 12 patients (24 percent) ambulated, on average, 25 hours after surgery. In these

patients, the average morphine dose was 212mg of morphine during their hospital stay. Based on these preliminary results, despite the lower dose of morphine in patients who started ambulation within 24 hours, it is inconclusive that early ambulation results in lowered dose of morphine administration. All patients included in this review were discharged three to four days after surgery.

Conclusion: The results of this review shows that early ambulation in patients who underwent total hip or knee arthroplasty reduces the total amount of morphine administered per patient on average during their hospital stay. It is inconclusive whether this will potentially lead to a decrease in length of stay in the hospital and/or prevent potential opiate abuse. This review is on-going and final data analysis and recommendations will follow.

Submission Type: Evaluative Study

Session-Board Number: 2-040

Poster Title: Impact of early identification using a rapid PCR test with antimicrobial stewardship intervention in patients with blood cultures contaminated by coagulase-negative staphylococci

Primary Author: Andre Tran, Lake Erie College of Osteopathic Medicine, Florida; **Email:** andre.tran@rx.lecom.edu

Additional Author (s):
Mark Wilson
Lauryn Gazzia
Andre McMahon
Jamie Kisgen

Purpose: Blood cultures contaminated with common skin flora such as coagulase-negative staphylococci (CoNS) can complicate clinical interpretation and significantly impact patient care. Delays in organism identification may result in the administration of unnecessary antibiotics, diagnostic testing, and extend hospital length of stay. Rapid diagnostic tests using polymerase chain reaction (PCR) techniques can drastically reduce time to identification of CoNS. The purpose of this study is to determine whether early identification using a rapid PCR test combined with antimicrobial stewardship intervention for contaminated blood cultures can significantly reduce the use of anti-staphylococcal antibiotics and infection-related expenditures at a large community hospital.

Methods: This single-center, IRB-approved, retrospective pre/post study was completed and includes a randomized sample of 100 adult inpatients (50 in each group) with a positive blood culture for CoNS that is determined to be contaminated (defined as growth of CoNS from one blood culture when two or more are obtained). The pre-group (pre-PCR) consisted of patients admitted from January through September 2014 and the post group (post-PCR implementation) consisted of patients from January through September 2015. Exclusion criteria includes age less than 18 years, suspected/confirmed BSI requiring anti-staphylococcal (AS) antibiotics, neutropenia, duplicate or mixed blood cultures, and receipt of AS antibiotics prior to blood draw. The primary outcome measure is percent of patients in each group who receive more than 24 hours of anti-staphylococcal (AS) antibiotic therapy. Secondary outcome measures include percent of patients who do not receive any doses of AS antibiotics, percent of patients

who receive one dose of AS antibiotics, duration of AS antibiotic therapy (hours), time to pathogen identification (hours), total number of blood cultures performed, total number of vancomycin levels performed, percent of patients who have an infectious diseases physician consultation, hospital length of stay (days), and total hospital charges per patient (dollars). Descriptive statistics are used to characterize data and evaluate primary and secondary outcomes.

Results: One hundred patients were included in the final analysis (50 in pre-group and 50 in post-group). For the primary outcome, there was no difference in the number of patients who received anti-staphylococcal (AS) antibiotics for more than 24 hours (24% vs 14%, p=0.203). However, compared to the pre-group, patients in the post-group had a significantly lower number of patients who received AS antibiotics (54% vs 26%, p=0.004), had a shorter median time from positive culture to discontinuation of AS antibiotics (33.1 ±11.2 hours vs 21.7 ±12.2, p=0.019), and a lower percent of patients receiving a single dose of an AS antibiotic (20% vs 2%, p=0.008). In addition, the duration of AS therapy was longer in the pre-group (37.7 vs 27 hours, p=0.088) and time to organism identification was longer in the pre-group compared to identification utilizing rapid PCR testing (23 hours vs 1.88 hours). The median hospital length of stay (3.8 days vs 3.7 days, p=0.404), total number of vancomycin levels performed (2 vs 1), total number of blood cultures collected (140 vs 126), and percent of patients with an infectious diseases physician consult (48% vs 40%, p=0.42) were comparable in each group.

Conclusion: Based on these results, the use of rapid diagnostic tests using PCR techniques and antimicrobial stewardship notification can lead to significant reductions in the number of patients receiving AS antibiotics and time to discontinuation of AS antibiotics. However, length of stay and utilization of additional hospital resources were not statistically significant. Further research should aim at larger, multi-centered clinical study in order to evaluate the true clinical and economic impact of a rapid PCR diagnostic test in conjunction with pharmacist interventions in patients with contaminated blood cultures.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Descriptive Report

Session-Board Number: 2-041

Poster Title: Evaluation of empiric antibiotic treatment of febrile neutropenia in oncology patients

Primary Author: Kacie Ferracci, Lake Erie College of Osteopathic Medicine, Florida; **Email:** kacie.ferracci@rx.lecom.edu

Additional Author (s):
Christina Bachmeier
Christina Martin
Rebecca Toor
Kellen Danley

Purpose: In patients with chemotherapy induced neutropenia, fever may be the only sign of an underlying infection. Patients who present with fever and neutropenia are candidates for immediate empiric antibiotic therapy with an anti-pseudomonal beta-lactam. For patients with suspected methicillin-resistant Staphylococcus aureus (MRSA) infection or other resistant gram-positive cocci, treatment with vancomycin, daptomycin, or linezolid is recommended. The aim of this evaluation was to examine the utility and appropriateness of these agents as part of empiric therapy for neutropenic fever.

Methods: This was a retrospective chart review of 35 patient records between October 1, 2015 to September 1, 2016. Patients were included if they were over the age of 18, had a cancer diagnosis and were identified to have neutropenic fever upon admission at one of the four acute care centers of the Lee Memorial Health System, including Lee Memorial Hospital, Gulf Coast Medical Center, Health Park Medical Center, and Cape Coral Hospital. Chart information was obtained via an EPIC generated report that included patients assigned International Classification of Diseases (ICD) codes for Neutropenia, unspecified and Fever presenting with conditions classified elsewhere. Exclusion criteria included patients under the age of 18 and non-oncology patients. For the purpose of this study, febrile was defined as a single temperature ≥38.3°C or >38.0°C for over 1 hour and neutropenia was considered an ANC < 500/mm^3.
The primary objective of the study was to determine the approximate rate at which appropriate empiric therapy for patients presenting with neutropenic fever is initiated. Appropriate therapy

is defined as empiric treatment with one of the following agents: piperacillin/tazobactam, ceftazidime, cefepime, or a carbapenem and addition of gram positive coverage only if the patient had an indication.

Results: There were 35 patients reviewed for initial empiric treatment of febrile neutropenia. Of those examined, 33 were deemed appropriate per the standards outlined above. Vancomycin, linezolid, or daptomycin was administered as early empiric coverage in 24 patients. Of the patients initiated on vancomycin, linezolid, or daptomycin, 2 had positive blood cultures requiring gram positive coverage. Of the 22 patients with negative blood cultures, nine were kept on the medication without an indication for gram positive coverage. One patient was not initiated on any antibiotics and one patient was excluded from the review due to a locked patient file which was not accessible.

Conclusion: With the growing numbers of resistant organisms, antimicrobial management is a critical focus in health care. A balance of appropriate antimicrobial use and adequate patient care is crucial to positive outcomes. While nearly all patients reviewed were treated appropriately, many were overtreated with antibiotics for unknown indications. The findings of this review indicate that there is an area of need in promoting the removal of antibiotics without a clear indication.

Session-Board Number: 2-042

Poster Title: Strategies to identify patients with community-onset pneumonia caused by methicillin-resistant Staphylococcus aureus.

Primary Author: Sarah Didriksen, Lake Erie College of Osteopathic Medicine, Florida; **Email:** sarahdid724@gmail.com

Purpose: The imminent elimination of the healthcare-associated pneumonia designation precludes a necessity for the development of strategies to identify patients with community-onset pneumonia who will need broad spectrum empiric antimicrobial coverage due to likely infection with multiple drug-resistant organisms. The purpose of this study was to examine patient-specific risk factors to determine which are most likely associated with methicillin-resistant Staphylococcus aureus infection and the use of the risk factors identified to develop a modified risk scoring tool (based on the tool designed by Shorr et al.) to help identify patients that need empiric treatment with vancomycin.

Methods: This was a single-center, retrospective, case-control study. Patients were selected using a computer-generated search for positive methicillin-susceptible or methicillin-resistant Staphylococcus aureus respiratory cultures via TheraDoc. Patients with positive sputum cultures were included in this analysis if admitted to the hospital from January 2013 to July 2016. Exclusion criteria included direct admission to the intensive care unit. Risk factors used to assess patient profiles were extrapolated from current guidelines and various primary literature resources collected via an extensive literature search. Profiles were analyzed and odds ratios were employed to determine which risk factors were more likely associated with pneumonia caused by methicillin-resistant Staphylococcus aureus versus methicillin-susceptible Staphylococcus aureus.

Results: Risk factors that were identified as being more suggestive of MRSA included extremes of age (< 30 or >79), prior healthcare exposure (≤90 days), recent IV or oral antibiotic therapy (≤90 days), comorbidities (CVA, female with diabetes mellitus, dementia), current or recurrent influenza (≤30 days), current/history of MRSA colonization or infection (≤90 days), structural lung disease prior to admission, and a history of smoking. The modified risk scoring tool was created based on magnitude of odds ratios. No odds ratios related to individual risk factors were statistically significant, however, patients with positive methicillin-resistant

Staphylococcus aureus cultures tended to possess more (≥5) risk factors (OR = 10.5, p = 0.049) and an overall higher (≥6) risk score (OR = 10.5, p = 0.049) than those infected by methicillin-susceptible Staphylococcus aureus. Furthermore, it was found that if patients in this study had been assessed by the modified scoring tool, approximately 70% would have received appropriate empiric antimicrobial treatment, whereas, in actuality, only 35% of patients received appropriate empiric treatment within 24 hours of hospital admission.

Conclusion: The findings in this small study, however inconclusive, help to identify that there is a pertinent need for large, randomized clinical trials to determine risk factors that are associated with community-onset pneumonia caused by methicillin-resistant Staphylococcus aureus. Without a tool like the one developed here, many patients may receive initial antimicrobial therapy that is not optimal, selecting for bacterial resistance and resulting in undesirable therapeutic outcomes.

Poster Title: The role of oral biologic agents in the treatment of relapsing-remitting multiple sclerosis

Primary Author: Anna Marsakova, Lake Erie College of Osteopathic Medicine - Bradenton, Florida; **Email:** anna.marsakova@rx.lecom.edu

Additional Author (s):
Paul Twigg

Purpose: The purpose of this study is to evaluate available literature relating to the safety and efficacy of oral biologics in the treatment of relapse-remitting multiple sclerosis.

Methods: The following databases were searched: Medline (PubMed), Embase, and Ovid; using the search terms multiple sclerosis, MS, relapse, oral biologic, EDSS, RRMS, and relapsing-remitting.

Results: Four high quality phase III randomized placebo controlled trials were assessed. The research indicated that dimethyl fumarate and teriflunomide were both safe and efficacious therapies in the treatment of relapsing-remitting multiple sclerosis. Statistically significant reductions in absolute risk reduction, preventing relapses at week 108, lowering disability progression, and MRI endpoints were seen with both medications. Common adverse events seen with both therapies included diarrhea and nausea. Serious adverse events were more prevalent with dimethyl fumarate when compared to teriflunomide (17% vs 11%). Events leading to death were seen with both medications but were considered unrelated to the treatment.

Conclusion: Dimethyl fumarate and teriflunomide can both be considered relatively safe and more efficacious when compared to placebo. More studies in the form of head to head trials versus other biologic agents are needed to find their place in the treatment process. Currently both can be considered convenient, safe, and effective agents.

Poster Title: Detection of emerging research trends by biomedical text mining algorithms

Primary Author: Majid Mirzai, Lake Erie College of Osteopathic Medicine - Bradenton Campus, Florida; **Email:** majid.mirzai@rx.lecom.edu

Additional Author (s):
Tyler Chia
Reid Orenstein
Anish Patel
Sachin Devi

Purpose: PubMed is the largest database of biomedical literature that contains over 25 million citations. Analyzing this vast number of articles, coupled with rapid rate of publication, presents a challenge to the scientific community. Therefore, there is a need for a high-performing scalable tool to identify emerging novel scientific trends. We hypothesized that analyzing the titles of the scientific articles can assist in identifying emerging research trends. In the present study, text mining algorithms were used to unearth novel and emerging scientific trends using the case study of "obesity as research interest."

Methods: Article titles containing the word "obesity" were downloaded from PubMed. A primary text mining algorithm developed in Visual Basis 6.0 (VB6) was used to calculate word frequency. All words since year 1880 were used to create a data visualization technique known as "word cloud." Words that appeared more frequently were presented larger than words that appeared less frequently. Average percentage increase in word frequency was then calculated for all words over the period of five years (2011-2015) to identify the emerging trends in obesity. A secondary text mining algorithm was developed to filter unique words that appeared for the very first time in 2015 along with the word "obesity" in order to identify the most recent scientific trends.

Results: A total of 58,215 articles containing the word "obesity" were downloaded from PubMed. The primary text mining algorithm found the words with highest frequency were "obesity" (n=39,830), "treatment" (n=3,758), "risk" (n=3,382), and "childhood" (n=3,052). Over the five years from 2011 to 2015, average percentage change found an increase in the terms

"nonalcoholic" by 750%, "placental" by 680%, "microbiome" by 680%, and "dopamine" by 580%. In 2015 alone, the secondary algorithm uncovered over 100 terms that were not previously present. Biomarkers, genes, proteins, etc. were discovered as novel therapeutic targets associated with obesity. These terms represent potential obesity-related novel therapeutic targets that can be used for future research.

Conclusion: This study demonstrates the ability of a text mining algorithms to uncover emerging research trends that would normally be buried under the vast number of publications.

Poster Title: Isoproterenol: reducing cost without increasing heart rate

Primary Author: Elizabeth Faville, Lake Erie College of Osteopathic Medicine - Bradenton, Florida, Florida; **Email:** efaville107@icloud.com

Additional Author (s):
Brian Brown
Russell Sayles

Purpose: In 2015, the price of isoproterenol drastically increased from $50 per ampule to the current price of $1,685. Isoproterenol, a nonselective beta receptor agonist, is utilized in both the critical care setting for the treatment of bradycardia as well as the catheterization lab to stimulate arrhythmias during electrophysiology (EP) studies. At The Johns Hopkins All Children's Hospital, the use of isoproterenol was reviewed over a one year time period to determine if drug use could be decreased. In addition, the location and the amount of isoproterenol stocked were evaluated to determine if inventory could be reduced.

Methods: Data were collected from June 2015 through May 2016. Data collected included: patient demographics, if a drip was dispensed and started, number of ampules used, and indication. The location of isoproterenol stock was determined in pharmacy and patient care areas. The amount of ampules purchased during the same time period were determined from purchase orders, and the number of ampules deemed expired were calculated.

Results: A total of 77 orders for isoproterenol drips were identified in the data collection time period. Indications included EP study (56), heart transplant (12), tilt test (5), other (4). Seventy-one drips were dispensed, with 37 drips (52.1%) started. Heart transplant started 27% (3/11) of the drips dispensed, EP Lab 63% (33/52), tilt test 0% (0/4), and other 25% (1/4). The drips not started wasted 54 isoproterenol ampules. In addition to being stocked in pharmacy, 88 ampules of isoproterenol were stocked in transport bags and code cart trays. No isoproterenol was documented being used from a code tray or on transport during the time period. One hundred and fifty-one ampules were purchased by pharmacy and 97 were calculated as being used. An estimated 54 vials were wasted due to expiration. A total of 108 ampules of isoproterenol were calculated to be wasted.

Conclusion: The results reveal an excessive waste of isoproterenol. An action plan was developed and will be presented at Pharmacy & Therapeutics. The committee approved the removal of isoproterenol from code trays, by adding it to the CVICU Pyxis machine for emergencies. A STAT drip will be dispensed if needed. For EP studies and heart transplants, pharmacy and cardiology will develop a process to only dispense a drip when needed. If a drip if deemed necessary prior to heart transplant, the 0.02 mg/mL standard concentration will be dispensed. The recommended action plan would save the hospital approximately $180,000 per year.

Poster Title: Impact of pharmacy interns-managed ambulatory epoetin clinic

Primary Author: Alena Korbut, Lake Erie College of Osteopathic Medicine (LECOM) and School of Pharmacy, Florida; **Email:** americalena@yahoo.com

Additional Author (s):
Cheelove Cineas
Tabitha Hendricks
Gillian Staikos

Purpose: Anemia secondary to Chronic Kidney Disease (CKD) reduces erythropoietin production and shortens red blood cells (RBC) survival. Due to severe adverse effects associated with use of Erythropoietin alfa (Epo), anemia in CKD is best managed in collaboration with health care professionals familiar with the medication and using a protocol to guide treatment decisions. The purpose of this study was to determine pharmacist/intern impact on management of Epo in patients with anemia secondary to CKD in an outpatient erythropoietin clinic (OEC).

Methods: The institution's ethics committee reviewed and approved this open-label retrospective chart review study that was conducted for patients with anemia in CKD over the age of 18 seen at Desoto Memorial Hospital (DMH) outpatient clinic from September 11, 2015 through September 11, 2016. Patients with active malignancy, cerebrovascular accident within last 12 months as well as or patients with End Stage Renal Diseases (ESRD) were excluded from the review. Based on the clinic protocol, the goal hemoglobin (Hgb) was 10-11g/dL and Epo dose was initiated at either 10,000units subcutaneously once weekly or 20,000units subcutaneously once every 2 weeks. The primary outcome was percent of patients with a mean Hgb at target goal after OEC implementation. Secondary outcomes included the difference in the mean dose of Epo, total time to reach Hgb target goal, and whether or not Iron studies were performed before and after OEC implementation. Mean initial Hgb values before OEC implementation were compared to mean final Hgb values and the patients' therapeutic ranges were also assessed. A retrospective survey was also obtained from each patient to evaluate Quality of Life (QoL).

Results: The mean difference between Hgb values before pharmacy took over and after was 0.11 percent (n equals 11, 95 percent CI, -1.18 percent to 0.95 percent, P equals 0.813). Due to the sample size being too small we did not observe statistical significance, however, we saw significant clinical impact on patients and their QoL. By obtaining a survey where the patients had to answer if their overall QoL and Activities of Daily Living (ADLs) improved, stayed the same, or worsened, ten people answered that their QoL and ADLs were significantly improved and five people said they stayed the same or worsened. Epo doses significantly decreased when pharmacists took over. The difference in mean Epo dose before and after pharmacy assumed control was 13,668 units (n equals 7; 95 percent CI, 503.5 to 26832.6, P equals 0.0441). Dose reduction resulted in substantial savings for the patient. Hospital savings resulted in 46 percent decrease or an average overall savings of 1010 dollars per month.

Conclusion: A pharmacist/intern-managed outpatient erythropoietin clinic plays a significant role in maintaining stable patient Hgb levels, decreasing total Epo doses and improving QoL for patients with anemia secondary to CKD. Future studies with a larger sample sizes are recommended to reach statistical significance.

Submission Category: Ambulatory Care

Poster Title: Impact of a pharmacist-managed asthma clinic on rural emergency room visits in Indian Country

Primary Author: Sherry Daker, Lake Erie College of Osteopathic Medicine (LECOM) Bradenton School of Pharmacy, Florida; **Email:** sherry.daker@rx.lecom.edu

Additional Author (s):
Gayle Tuckett
Alena Korbut
Axel Vazquez-Deida

Purpose: In 2010, asthma accounted for 439,400 hospitalizations and 1.8 million emergency department visits, being a significant public health burden in the United States. In October 2014, an Asthma Management Clinic (AMC) was established at Tse'hootsooi' Medical Center (TMC) in Fort Defiance, AZ. The AMC was created to educate patients with persistent asthma on their disease and the medications used to treat their disease, in order improve their asthma control and quality of life, and decrease their hospitalizations and ED visits. This study was conducted to assess the effects of a pharmacy-managed asthma clinic in a rural, tribal hospital.

Methods: The institution's ethics committee reviewed and approved this open-label retrospective chart review study that was conducted for patients with asthma seen in the AMC from October 1, 2014 through September 30, 2015. The items assessed include: ED visits and asthma control test (ACT) scores, and the items to be assessed include: hospitalizations and oral corticosteroid (OCS) use. The number of ED visits one year prior to clinic initiation were compared to the number in the year following clinic initiation, and initial ACT scores were compared to final ACT scores within the designated chart review timeframe.

Results: There were a total of 41 ED visits prior to clinic initiation. After a year of being seen in the AMC, ED visits totaled nine showing a 78% decrease in ED visits. The number of patients with an initial ACT score >19, indicating they are well controlled, were three compared to 12 for those having a >19 final ACT score.

Conclusion: A pharmacy-run asthma management clinic plays a significant role in decreasing asthma-related ED visits and improving asthma control.

Submission Category: Ambulatory Care

Submission Type: Descriptive Report

Poster Title: Evaluation of pharmacist-led smoking cessation patient education and follow-up program on quit rates at an ambulatory care clinic for low-income, medically underserved, uninsured patients

Primary Author: Margaret Emerson, Lake Erie College of Osteopathic Medicine (LECOM) School of Pharmacy, Florida; **Email:** s.margaret.emerson@rx.lecom.edu

Additional Author (s):
Loreto Lapeiretta
Alejandro Vazquez

Purpose: The goal of this study was to determine if participation of low-income, medically underserved, uninsured patients in the pharmacist-led smoking cessation group education classes and follow-up visits at Turning Points One Stop Clinic in Bradenton, Florida increased their likelihood of successfully quitting smoking. Additionally, we aimed to determine areas of performance improvement associated with smoking cessation group patient education classes, motivational interviewing, and the pharmacist and pharmacy student practice model.

Methods: A retrospective chart review was conducted on all patients who participated in a one-time smoking cessation group education class and subsequent bi-monthly follow-up visits at Turning Points One Stop Clinic between January 1, 2010 and August 9, 2016. An ambulatory care specialty pharmacist and final-year pharmacy students conducted smoking cessation classes and patient visits in collaboration. Pertinent patient demographic information including age, gender, race, and socioeconomic status or homelessness was obtained. Patient encounters were assessed for dates and appropriate time frames of follow-up visits, changes in cigarette smoking, types of nicotine replacement therapy (NRT) or other quit method utilized and compliance, adverse effects and other barriers to quitting, and percentage of setting quit dates.

Results: A total of 70 profiles of patients who attended smoking cessation group education classes and follow-up visits between January 1, 2010 and August 9, 2016 were assessed. Among these patients, 22.8% (n=16) were homeless at the time of data collection. Dual NRT therapy (gum + patch or lozenge + patch) was utilized by 64.2% (n=45) of patients and single NRT therapy (gum, lozenge, or patch alone) was utilized in 31.4% (n=22) of patients. A quit date was

set by 44% (n=31) of patients and 48.5% (n=34) of patients adhered to appropriately scheduled follow-up visits. 20% of patients (n=14) were lost to follow-up. 17.1% (n=12) of patients successfully quit smoking and among those who quit, 25% (n=3) were homeless. 91.6% of quitters (n=11) were 1 pack-per-day (ppd) smokers prior to quitting. 1 patient successfully quit with Zyban (bupropion). 100% of quitters who had set quit dates (n=5) achieved their goal quit date. Stress associated with lower socioeconomic status was cited as the most common barrier to quitting, followed by triggers associated with living with or interacting with current smokers. For performance improvement, we determined that the clinic would benefit from streamlining patient interviews and developing more comprehensive patient encounter templates.

Conclusion: Our study found that the quit rate for patients in a pharmacist-led smoking cessation program in the ambulatory care setting is higher than national quit rates. Smoking cessation was also achieved in a significant percentage of homeless patients. Specific factors for success were the use of dual NRT therapy, setting goal quit dates, and adherence to bi-monthly follow-up visits. Areas for performance improvement include motivational interviewing content and documentation within patient encounters. Our ongoing smoking cessation program is an example of successful collaboration between pharmacists and pharmacy students within an ambulatory care clinic.

Poster Title: Benefit of adding carbamazepine to the treatment regimen of a patient with aggressive alcohol needs going through withdrawal

Primary Author: Lindsey Smith, Lake Erie College of Osteopathic Medicine School of Pharmacy, Florida; **Email:** lindsey.smith@rx.lecom.edu

Additional Author (s):
Stephen Geisler

Purpose: This case report illustrates the benefits of using carbamazepine in managing patients with alcohol withdrawal, as well as the importance of pharmacist recommendations in regards to patient care. The patient presented to the emergency room after being hit by a car while walking in the street and had a blood alcohol concentration of 0.20, altered mental status, tachycardia, tremors and appeared critically ill. He has a significant history of substance abuse, consuming alcohol daily and occasionally smoking tobacco and crack cocaine. CIWA-Ar protocol was initiated for the patient to help control withdrawal symptoms such as seizures and agitation. During the first two days of therapy, his withdrawal was managed with lorazepam, divalproex, gabapentin, midazolam, haloperidol and thiamine. The patient was intubated and the average CIWA-Ar score for day 1 of treatment was 24.29. Benzodiazepines are considered to be the current standard of therapy for alcohol withdrawal treatment given the abundance of literature available to support their use, which is why the clinicians initiated a benzodiazepine. The next five days of therapy the patient was controlled solely on lorazepam and haloperidol, and had an average CIWA-Ar score of 19.27 (min = 2 and max = 40). During the time the patient was on lorazepam and haloperidol, he was able to be extubated and started on a liquid diet. On day 8, the patient had haloperidol removed from his treatment plan and aggressive alcohol needs resulted in the clinicians adding vodka to the patient's regimen to help combat developing delirium tremens. The patient was allowed up to 8 servings (50cc) of vodka daily, which helped the CIWA-Ar score stay around 13.07. Then, on day 15 of treatment, gabapentin was reintroduced with the lorazepam and vodka, as well as 1 beer every 2 hours. This new regimen lasted 8 days and brought the CIWA-Ar average down to 6.25. An attempt to wean the patient off of the alcohol was unsuccessful since he began experiencing seizures. On day 26 of treatment the patient was experiencing anxiety about not being able to be discharged since he is unstable when he stops drinking, and a clinical pharmacist intervened and recommended to

taper down the alcohol intake and initiate carbamazepine 200mg PO TID with CIWA-Ar checks every hour. The new changes to the patient's treatment allowed the patient to be safely discharged 7 days later and brought the average CIWA-Ar score down to 2.2. Recent literature is starting to explore alternative agents to benzodiazepines in patients with alcohol withdrawal and carbamazepine is one of the agents that is getting more attention. Carbamazepine lacks the potential for addiction and abuse that is associated with benzodiazepines, which is just one reason why it may be a desirable option for this patient population since many of them are already battling addiction issues. This case further supports the literature that is out there as it displays the benefits of adding carbamazepine to patient's regimens who are being treated for alcohol withdrawal. In addition, this case is a good example of the importance of advocating for your patients as a pharmacist and not being afraid to make suggestions that might not be familiar to the clinicians. Part of being a clinical pharmacist includes being a self-learner to stay up to date on the current literature so you can practice evidence based medicine to its maximum capacity. The pharmacist in this case noticed a trend in recent literature regarding the use of carbamazepine in patients with alcohol withdrawal compared to benzodiazepines and was able to bring this information to the physicians and help improve the patient's recovery to get him discharged quicker.

Poster Title: Student pharmacists' clinical interventions on multidisciplinary patient care rounds in a community hospital

Primary Author: Justin Presutto, Lake Erie College of Osteopathic Medicine School of Pharmacy - Bradenton Campus, Florida; **Email:** justin.presutto@rx.lecom.edu

Additional Author (s):
Lisa Hymel
Michael Watstein

Purpose: Sarasota Memorial Hospital [SMH] is an 819 bed regional medical center and the second largest acute care public hospital in Florida. The pharmacy at SMH practices both a centralized and de-centralized model with clinical pharmacists represented in different areas such as emergency medicine, pediatrics, infectious disease, and oncology. SMH provides students an opportunity to work with other healthcare professionals in these specialties providing clinical recommendations while further developing the students' knowledge and professional growth. The purpose of this study is to illustrate the role of a student pharmacist during multidisciplinary patient care rounds in addition to other student activities.

Methods: This is an institutional review board approved single center, retrospective analysis of patients admitted from June 6th to August 19th, 2016. An interdisciplinary team, including a pharmacy student rounded on all patients admitted on the oncology unit. Patients younger than 18 years of age, pregnant patients, and do not resuscitate patients were excluded. A pharmacy student rounded daily with the nurse manager and the case manager. The student reviewed patient profiles prior to and following patient interviews. Patient interviews focused on open ended questions on side effects, pain management, allergies, and drug therapy both at home and while in the hospital. All student recommendations were verbally discussed with the unit based pharmacist. The pharmacist would then discuss the recommendation with the attending physician if warranted. The student recorded all proposed interventions daily in Quality CompassR, a web based software program designed for structured patient care documentation along with patient's age, sex, length of stay, type of intervention, acceptance or decline of recommendation, physician, brief description, and other activities.

Results: During the 3-month period, 268 patient interviews were conducted. Student pharmacist's acceptance rate was 96 % (77 out of 80 recommendations). Of the 96% accepted interventions 38.9% were patient counseling, 27.2% were drug therapy add on, and the remaining 33.9% consisted of drug discontinuation, non-renal dose adjustments, medication reconciliations, allergy assessments, and drug re-scheduling.

Conclusion: This study demonstrated student pharmacists can be valuable members of a multidisciplinary team in the hospital setting. Student pharmacists provide a valuable service to patient care by identifying and solving drug related problems, including patient counseling, resolving medication discrepancies, allergy assessment, and add-ons to drug therapies.

Poster Title: Pharmacy technicians' assistance in pharmacist-delivered medication therapy management: A report from the ACO Research Network, Services and Education (ACORN SEED).

Primary Author: Myoanh Nguyen, Nova Southeastern Univeristy, Florida; **Email:** myoanh@nova.edu

Additional Author (s):
Sanna Siddiqui
Gregory Suhrheinrich
Stephanie Gernant

Purpose: Medication Therapy Management (MTM) is a pharmacist-provided service that improves clinical and economic outcomes. Knowledgeable and effective support staff is critical to the provision of MTM, As administrative support allows the pharmacist to dedicate more time to provide quality patient centered care.. Due to a wide variation in MTM delivery it is unknown how support staff, such as the pharmacy technician, could be best utilized. Therefore, the purpose of this research was to characterize existing literature describing pharmacy technician-provided support for MTM services.

Methods: In August 2016, A PubMed (MEDLINE) literature review was conducted by searching keywords such as pharmacy technician, medication therapy management, follow-up, communication, admission, discharge, patient education, drug therapy problem, motivational interviewing, medication history, disease management, and the MTM Core Elements Version 2.0 (medication therapy review, personal medication record, medication action plan, intervention, referral and documentation). Additional studies were identified by reference analyses. Included articles must have a description of pharmacy technician assistance in at least one MTM Core Element. Articles that described pharmacy technicians' assistance in theoretical scenarios or with mock patients were excluded. After title review, abstracts were independently reviewed by three researchers; researchers consulted on inclusion/exclusion discrepancies until consensus was reached. Descriptions of the pharmacy technician's function were characterized from each article and loaded into Research Electronic Data Capture (REDCap).

Results: A total of 217 articles were retrieved from the PubMed (MEDLINE) search. After duplicates were removed, a 159 abstracts were reviewed. 40 articles met inclusion criteria and were fully reviewed. 57.5% of articles had been published within the last two years. Articles were most likely to describe technician's assistance in MTM by completing medication reconciliation (77.5%). Articles were likely to describe patient education and monitoring (45%), documentation (30%) provider referral and communication (20%). Articles were least likely to describe follow-up (12.5%), patient information gathering (7.5%), personal medication record development (7.5%), and recruitment (2.5%). No articles described technicians' assistance in development of medication action plans.

Conclusion: Pharmacy technicians have most often being utilized to provide medication reconciliation, patient education and provider communication to support pharmacist-provided MTM. As medication action plan development requires precise clinical expertise only held by the pharmacist, it is expected pharmacy technicians would not provide administrative support for that MTM component.. Interventions, such as education and training programs, aimed at pharmacy technicians may improve support staff's efficacy and benefit MTM delivery in the future.

Poster Title: Stepping into the future: Incorporating chronic disease management into wearable technology

Primary Author: Doaa Alkiswany, Nova Southeastern University, Florida; **Email:** doaa.alkiswany@gmail.com

Additional Author (s):
Elena Pop
Jennifer Boisselle
Jennifer Le
Maria Pinto

Purpose: The purpose of our study is to report emerging trends and propose an idea of future blood glucose monitoring technology.

Methods: A literature search was performed using PubMed and EMBASE databases about health fitness trackers. Searches included only English language journals and full text studies published through March of 2016. An online search was conducted to inquire about health monitoring trackers currently available in the market. The search terms used were: heart tracker, monitor heart rate, activity, fitness tracker accuracy, blood sugar and health monitoring. Person interviews were conducted with over 100 people including patients, physicians, and pharmacists to assess interest and possible needs in an innovative health wearable tracker.
Example questions asked to patients: how you feel about having all in one future monitoring tracker that documents your information into one application/program? What are some features that you would like to have in such a product? Would you benefit from having your information automatically updated into a unified electronic system available to your healthcare team?
Questions asked to physicians: how would you benefit from a future product that loads patient's health information automatically into an easy accessible program? Finally, pharmacists were asked: would you benefit from monitoring patients who are on diabetes medications? Would it be easier to counsel patients knowing their glucose levels and medications?

Results: Health tracker devices currently on the market track number of steps, calories burned, distance traveled, and sleep habits. Approximately 69% of adults tracked a health indicator for themselves or loved ones, and 21% of them used technology to track. 40% of adults who track a health indicator, have one chronic condition and 62% have two or more chronic conditions. In order to better manage diabetes and minimize health care costs, a future noninvasive glucose monitor/tracker would be a great intervention for diabetics. Integrating "Reverse Iontophoresis technology", which uses electric current going through the sensors and collecting glucose samples from body fluids would be the ideal mechanism. Incorporating this technology into a wristband that would monitor patient's blood glucose, and combining other features such as blood pressure, calories burnt, activity/inactivity time and medication adherence alarm, will drastically impact diabetics lifestyle and future. Furthermore, the interview results showed that all patients, pharmacists, and physicians expressed a high level of enthusiasm regarding a future noninvasive technology tracker that could potentially lower the healthcare cost and prevent future health complications.

Conclusion: The innovation of noninvasive glucose monitoring has the potential to revolutionize diabetes care by improving adherence to blood glucose testing and providing continuous feedback to the patient and their physician. Such technology has the potential to drastically lower healthcare costs by eliminating the need for purchase of test strips, lancets, unnecessary doctor's visits, avoidable urgent care visits, and complications from diabetes.

Poster Title: A Retrospective Analysis of the Incidence and the Predictors of Hypoglycemia in Inpatients Receiving Insulin Glargine

Primary Author: Nour Samra, Nova Southeastern University, Florida; **Email:** ns957@nova.edu

Additional Author (s):
Dima Samra

Purpose: Hypoglycemia in the inpatient setting has been correlated to an increased risk of morbidity and mortality when diabetic patients are placed on an insulin regimen. The aim of this analysis is to evaluate incidence of hypoglycemia and related risk factors in a group of patients on insulin glargine admitted inpatient.

Methods: Following Institutional Review Board approval, a retrospective, single center electronic record review was performed on diabetic inpatients receiving insulin glargine during April 1, 2016 to June 30, 2016. Demographic information, feeding status, renal function, home diabetes regimen, fasting and non-fasting glucose levels and admission reason were collected through the electronic medical record. Patients were included in the study if they were diagnosed with diabetes, received at least one dose of insulin glargine, and had at least 24 hours of blood glucose data available. A hypoglycemic glucose level was defined as less than 70 mg/dL.

Results: A total of n=253 patients in the medical center were reviewed. Among those reviewed, 37.5% (n=69) exhibited hypoglycemic events. Among the patients that experienced hypoglycemia, 85.5% (n=59) were above 65 years of age, 89.9% (n=62) had a renal function CrCl< 30 ml/min, 29% (n=20) were NPO, and 77% (n=53) were patients that were continued on their previous home regimen when admitted inpatient.

Conclusion: Hypoglycemia in hospitalized patients with diabetes is associated with continuing home regimen of insulin glargine upon admission, decreased renal function, nutritional feeding status, and age above 65. Identification of patients at increased risk of hypoglycemia may be important for optimally adapting treatment and patient management.

Poster Title: Pharmacist's Role in HF patients Transition of Care: RCT

Primary Author: Fatimah Sherbeny, Nova Southeastern University, Florida; **Email:** fs423@nova.edu

Additional Author (s):
Barry Bleidt

Purpose: To assess the effectiveness of pharmacist-provided hospital discharge education, for heart failure patients, in improving patients' knowledge and self-efficacy. Also, to assess the impact of this intervention on the rate of hospital readmission and emergency visits at 30-days, 60-days and 90-days after discharge.

Methods: This study is a randomized, interventional, test-retest, control group clinical trial. We will compare HF patient's knowledge and self-efficacy, between a control and intervention groups, at baseline and at different time points after their discharge from the hospital. Both the control and intervention groups will follow the usual and standard care available at West Kendall Baptist Hospital, while the intervention group will receive:
1- A phone call 48h-72h after discharge from the hospital to ensure that the patient filled their prescriptions and started taking their medication.
2- A phone call five to seven days after discharge to reinforce the education using the "teach back technique" . Patients will be asked about their medications, what are they for, how to use them, and what side effects to watch for, based on the education and information that was provided to them at discharge.

Results: In progress

Conclusion: This study has the potential to significantly impact the transitional care of HF patients and positively affect the rate of readmissions for the better, and boost the role of the pharmacist as a key interdisciplinary team member. It also support the role of the pharmacist as a promoter of health and provider of tools to enable HF patients to care for themselves after discharge from the hospital.

If the hypothesis of the study holds true, the results can be shared outside of WKBH and BHSF to affect care of not only HF patients, but patients with other disease conditions.

Poster Title: Evaluating the need for interprofessional education among health care professional students

Primary Author: Vera Zaldivar, Nova Southeastern University, Florida; **Email:** vz35@nova.edu

Additional Author (s):
Leah Bensimon
Diana Hernandez
Giselle Farinas
Diana Christie

Purpose: The educational environment is the starting point of strong healthcare systems. In recent publications, the overwhelming need for collaboration amongst healthcare professionals was reported. In order to serve this need, we aim to evaluate the need for interprofessional education through hands on guided learning among a variety of health care professional students at Nova Southeastern University.

Methods: This study was completed at Nova Southeastern University (NSU) Health Professions Division (HPD) between January and March, 2016. Surveys were created by Google Forms © and advertised through social media and personal emails to assess several parameters necessary to incorporate an interprofessional course in each program's curriculum. Surveys were directed towards HPD students, Faculty members, Deans, and Interdisciplinary Curriculum Committee Members. Questions within the survey were strategically created to gather thorough responses regarding the need and feasibility of the course.

Results: More than 400 subjects were targeted and 80 responses were gathered overall. The majority of student responses were significantly in favor of the implementation of an interprofessional course that incorporates hands on training alongside other healthcare disciplines within a patient-centered environment. The responses from the curriculum, faculty, and interprofessional committee encourage the need of such a course, and they provided valuable data on suggestions and guidance for such initiative.

Conclusion: Given the need for an interprofessional course at NSU HPD, we envision building a course that will balance clinical skills as well as interpersonal strengths that will prepare students for their destined profession to ultimately maximize patient care. The key to a successful course will be collaboration between the different colleges within HPD.

Session-Board Number: 2-056

Poster Title: Effect of Interdisciplinary rounds on Enteral Nutrition in mechanically ventilated ICU patients

Primary Author: Jane Ai-Chen Ho, Nova Southeastern University, Florida; **Email:** ah1700@nova.edu

Additional Author (s):
Lori Milicevic
Jinesh Mehta

Purpose: The 2016 American Society of Parenteral and Enteral Nutrition (ASPEN) guidelines for the adult critically ill patient recommend that enteral nutrition (EN) to be started within 24-48 hours in patients who are unable to maintain volitional intake. EN maintains the integrity of the gut, modulates stress and attenuates disease severity. Interdisciplinary rounds (IDR) has shown improvement in length of stay in various studies, but not yet in EN starting time in ICU patients. The purpose of the study was to evaluate the effects of IDR in the hospital with regards to its effect on the initiation timing of EN therapy.

Methods: The institutional review board approved this quasi-experimental pre-post study design to evaluate the percentage of mechanically ventilated patients who started EN within 48 hours, before and after the initiation of IDR in the medical and surgical ICU patient population. Patients were included if they were greater than 18 years of age, admitted to the ICU and mechanically ventilated for greater than 48 hours. The "pre" data was collected from January 1 to May 22 of 2016 before the implementation of IDR. The "post" data was collected from May 22, of 2016 to July 29, 2016 after IDR were implemented. Statistical analysis was performed using the Fisher exact test.

Results: 41 patients (29 medical ICU, 13 surgical ICU) were evaluated in the pre group. Demographics: 46% female, 54% male, 39% below the age of 60, 61% above the age of 60, diagnosis: 46% respiratory failure, 27% sepsis, 4.8% cardiac arrest, 4.8% seizure, 4.8% chronic heart failure, 4.8% liver failure, 4.8% gastrointestinal bleeding, 3% coronary artery disease. The percentage of patients who started EN therapy within 48 hours was 27%, while 73% were started beyond 48 hours ($P < 0.05$). 28 patients (17 medical ICU, 11 surgical ICU) were evaluated

in the post group. Demographics: 46% female, 54% male, 29% below the age of 60, 71% over the age of 60, diagnosis: 57 % respiratory failure, 21% sepsis, 18% liver failure, 4% gastrointestinal bleeding. 71% of these patients started EN within 48 hours, 29% were started beyond 48 hours (P < 0.05).

Conclusion: Before the start of IDR in the medical and surgical ICU, close to three-quarters of the patients were started on EN beyond 48 hours. After IDR began, more than two-thirds of patients were started on EN within 48 hours. Interdisciplinary rounds significantly improves time to start EN in critically ill mechanically ventilated patients.

Submission Category: Ambulatory Care

Submission Type: Descriptive Report

Session-Board Number: 2-057

Poster Title: Innovating diabetic healthcare and mobile monitoring

Primary Author: Natalia Cadavid, Nova Southeastern University, Florida; **Email:** nc737@nova.edu

Additional Author (s):
Ariel Ferdock
Nicole Mahabir Herrera
Maritsa Monokandilos
Melanie Schreiber

Purpose: Diabetic monitoring is a difficult, yet necessary task in young patients. Standard blood glucose monitoring (SBGM) offers accurate, real time measurements, but requires multiple daily finger sticks and bulky, indiscreet equipment. Continuous monitoring systems (CMS) are able to track glucose levels without the use of finger pricking, allow for closer monitoring, and alert when substantial changes in levels are present. However, these are expensive and exhibit limitations in their monitoring capabilities. The objective of this study was to compare current blood glucose monitoring technologies for future development of an affordable, discreet, efficacious mobile application-linked monitoring system for adolescents with diabetes.

Methods: A survey was disseminated using potential stakeholders for the glucose monitoring prototype in order to identify desirable features and designs. Those surveyed included physicians, nurses, pharmacist, hypertensive patients, diabetic adolescents and their parents, and IT personnel. Questions addressed adherence, practicality of a new product, willingness to use a new products, and the estimated cost to make a product. This was followed by a literature review using EBSCOhost and PubMED databases from Nova Southeastern University (NSU) electronic library. The keywords searched were glucometer, diabetes, mobile, health application, continuous glucose monitoring system, bloodless glucose monitoring system, noninvasive, and technology. Inclusion criteria included full-text articles of randomized controlled trials, observational studies, review articles, or case reports written in English from 2000 to 2015. Exclusion criteria consisted of articles related to disease states other than diabetes. The primary objective was to compare the accuracy and efficacy of SBGM and CMS.

Results: Fifty-two articles were found. Of these, 44 articles met inclusion criteria. It was found that CMS provides more information regarding a patient's glucose trends and vital warnings; however, these are not reliable replacements for SBGM as hardware malfunctions have been documented causing false alerts, lag times, and usage difficulties. Current mobile application fell into four categories of available features that they offered: Decision Support (17%), Communication (83%), Patient Health Record (21%), and Education (18%). It was observed that only one mobile application was HIPAA compliant. Primary features of mobile applications included medication reminders, blood glucose monitoring, diet management, and a fitness tracker. Secondary features included education, weight/BMI, blood pressure, communication, social networking, and integration with patient health records.

Conclusion: Current mobile applications are not patient–centered and do not reliably relay blood glucose trends to healthcare providers. A prototype product that links SBGM and a mobile application capable of monitoring, trending, and warning a patient in real time would form a bridge between the two currently used systems to ensure positive outcomes for adolescent patients and their parents. NSU College of Pharmacy students are currently in development of a product, GlucoHealth, to fit these needs.

Submission Category: Automation/ Informatics

Submission Type: Descriptive Report

Session-Board Number: 2-058

Poster Title: Prevention of adverse drug events via a computerized monitoring system following pharmacy student intervention in a tertiary care teaching hospital

Primary Author: Justin Sterling, Nova Southeastern University, Florida; **Email:** js3611@nova.edu

Additional Author (s):
Suasy Acevedo-Muñiz
Marta Miyares

Purpose: Computerized monitoring has effectively detected and prevented adverse drug events in hospitals nationwide. Active daily interventions by a pharmacist are required to help provide optimal patient care. Pharmacy students are a valuable resource to aid in this patient safety initiative; allowing the pharmacist to focus on different aspects within their scope of practice. We assessed the ability of pharmacy students to identify potential adverse drug events in a tertiary care teaching hospital.

Methods: Pre specified safety alerts generated by a commercial surveillance application were prospectively evaluated. We examined predefined alerts based on the hospital's specific needs such as warfarin and international normalized ratio greater than 3, enoxaparin dosing according to creatinine clearance, elevated potassium greater than 5.5 millimoles per liter and culprit medications, and other alerts relating primarily to anticoagulation. The frequency, types of alerts produced, and medical records were examined by the pharmacy students on a daily basis and presented to the pharmacist in charge for evaluation of accuracy and causality. Verified potential adverse drugs events were subsequently presented to the medical team alongside a proposed intervention. All alerts, recommendations, and accepted interventions were documented in the electronic health record to ensure proper follow up. All institutional review board procedures were followed. Data was analyzed using descriptive statistics.

Results: Over a 4 week period 88 patients were screened and the system generated 192 alerts from the pre specified criteria of safety parameters. Among the 192 alerts, 23 (12 percent) were considered significant, warranting recommendations to the medical team. Of the 23 recommendations, 16 (70 percent) were due to warfarin and international normalized ratio

greater than 3, 2 were due to inappropriate concomitant use of warfarin and enoxaparin or heparin, 2 were due to incorrect renal dose adjustments of enoxaparin, 1 was due to the use of warfarin without proper indication, and 2 were related to medication adjustments due to hyperkalemia. Among the 16 patients found to have supratherapeutic international normalized ratio, 4 (25 percent) had an international normalized ratio greater than 4 and 2 patients were found to have significant warfarin drug interactions. All recommendations made were accepted by the medical team resulting in 23 preventable adverse drug events.

Conclusion: Screening for adverse drug events with a computerized monitoring system was effective at identifying these events when used as part of an active surveillance program. Anticoagulation resulted in 91 percent of overall recommendations, confirming a significant need for improvement in this area. Because of the high number of alerts relative to the number of significant interventions, an assessment of alerts will be conducted to disable those not clinically relevant. Due to understaffing coupled with the need to expand knowledge among pharmacy students, the incorporation of students plays an important role in ensuring surveillance programs are utilized to their maximum potential.

Poster Title: Improving chronic disease outcomes and lowering healthcare cost with the use of smart assistive technology

Primary Author: Emison Contreras, Nova southeastern university, Florida; **Email:** ec961@nova.edu

Additional Author (s):
David Pham
Akash Patel
Henry Pena
Armando Gil

Purpose: As the number of patients with chronic disease states grow, there provides a niche to help patients better manage their diseases with the help of a smart assistive technological tool. We propose said tool to monitor certain vital signs in addition to fall detection, medication and doctor appointment reminders and information storage so as to better target patient therapy.

Methods: A short 10 question closed-ended online survey questionnaire was shared within 7 Social media support groups and 2 Alzheimer's disease website forums. A sample (N=806) was collected

Results: Out of sample of 806, 99% of respondents had a friend or family member with Alzheimer's. The majority (95%) of the respondents were family members that provided care for their loved one afflicted by Alzheimer's disease. 802 (99%) respondents acknowledge Alzheimer's as a progressive disease and knew that it required monitoring. 598 respondents communicated with their family or friend with Alzheimer's disease every hour. 623 respondents are willing to purchase a device that would help monitor vital signs such as blood pressure, heart rate, sleeping patterns, medications, GPS tracking, fall monitoring and all while being recorded in the patient's electronic health record. 18% of respondents would first consider the price of the device before purchasing while 77% would purchase the device regardless of the price

Conclusion: Our short closed-ended question survey demonstrates the demand for a device that is able to monitor a patient's vital signs, location, medication reminders, doctor appointment reminders, sleeping patterns and the ability to detect and monitor falls.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Evaluative Study

Session-Board Number: 2-060

Poster Title: Adverse drug reactions and metabolic differences in patients receiving haloperidol decanoate every two weeks versus every four weeks in a long-term inpatient psychiatric facility

Primary Author: Sinziana Ungureanu, Nova Southeastern University, Florida; **Email:** su65@nova.edu

Additional Author (s):
Tiffany Harrison
Jose Rey

Purpose: Haloperidol decanoate, an intramuscular injection intended to be administered monthly, is a treatment option for chronically psychotic patients with non-adherence issues. In order to increase ease of administration, psychiatrists at a long-term inpatient psychiatric facility have been prescribing haloperidol decanoate every 2 weeks at half the maximum dose. Our primary objective was to document the differences in the adverse drug reactions for patients stabilized on either haloperidol decanoate 200 - 225 mg IM Q2weeks or 400 - 450 mg IM Q4weeks. Our secondary objective was to evaluate the differences in metabolic outcomes between the two dosing regimens.

Methods: A retrospective chart review was conducted evaluating the medical records between 2011 and 2013 of identified patients initiated on the maximum dose of haloperidol decanoate, 200 – 225 mg IM Q2weeks or 400 – 450 mg IM Q4weeks. Patients were included if they received at least 5 months of treatment on a stable dose of haloperidol decanoate. Demographic variables (age, gender, race and diagnoses) were collected. Per our primary objective, it was documented whether patients experienced one or more adverse events. Adverse events studied were restlessness, tremor, slow/slurred speech, unsteady gait, shuffling gait, mouth/tongue movement, fatigue, weight gain, and dry mouth. The secondary objective for this analysis was to compare the differences in the metabolic outcomes between the two treatment regimens. Liver function tests, hemoglobin A1c, total cholesterol, LDL/HDL, and triglycerides were collected at baseline and after 5 consecutive months on haloperidol decanoate.

Results: Overall, patients on the Q2 week dosing schedule experienced more side effects from haloperidol decanoate than patients on the Q4 week dosing schedule. In addition, more of these patients were treated with the EPS medications diphenhydramine and/or benztropine, which further implies that the movement ADRs were more prevalent in the Q2 week dosing group. In contrast, the Q4 week dosing group had a higher incidence of dry mouth and weight gain. There was no significant difference in metabolic outcomes, which included the average changes in liver function tests, total cholesterol, LDL/HDL and triglycerides.

Conclusion: For patients requiring a maximum dose of haloperidol decanoate, the Q2 week dosing schedule appears to be equivocal to the Q4 week dosing schedule. However, more movement-associated side effects were seen with the Q2 week dosing schedule, while more metabolic side effects were seen with the Q4 week interval. Physiologically based pharmacokinetic modeling is the next step in evaluating these two dosing regimens.

Submission Category: Emergency Medicine/ Emergency Department/ Emergency Preparedness

Submission Type: Descriptive Report

Poster Title: Evaluation of emergency department pharmacist involvement on medication reconciliation in an academic teaching institution

Primary Author: Shantal Alcoba, Nova Southeastern University, Florida; **Email:** sa745@nova.edu

Additional Author (s):
Aliercy Nunez Sanchez
Ramy H. Gabriel

Purpose: The impact of pharmacist involvement in a multi-disciplinary team has been well documented to improve patient outcomes. Furthermore, supporting research has demonstrated pharmacists conducting medication reconciliations in the emergency department (ED) reduce medication related adverse events and associated healthcare costs. As part of a hospital-wide safety initiative, pharmacy clinical services were incorporated into the emergency department to perform medication reconciliation upon admission. The purpose of this project was to validate the significance of having a pharmacist-led medication reconciliation program in the emergency department and utilize the results to help support the expansion of pharmacy services in the ED.

Methods: Medication reconciliations were completed during the initial triage for all patients by staff nurses. Pharmacists were assigned to the emergency department from 11am to 11pm Monday through Friday and 11am to 7:30pm on weekends. Once there was a disposition for admission, a review of the medication reconciliation was performed by the pharmacist and compared to the existing list. Sources for medication information included but not limited to: the patient, family or caregivers, nursing home or assisted living facility's medication administration record, phone call to patient's primary care provider and/or pharmacy. Updated medication list was placed in the chart before admission orders were given. Interventions were recorded under the following categories: wrong drug, incomplete medication information, medication omission, not on the medication or discontinued by provider, duplication of therapy and incorrect dose and/or frequency. Additionally, total number of medication discrepancies (by drug class) was documented.

Results: During a 6-month period (January 1, 2016 to June 30, 2016), the pharmacist completed medication reconciliation on 3,730 patients in the emergency room. The average number of home medications per patient was 10 (range 0 to 31). A total of 2,143 interventions were documented as follows: medication omission 835 (22.4%), incorrect dose/frequency 538 (14.4%), no longer on medication 395 (11.6%), medication information incomplete 229 (6%), wrong drug 88 (2.4%) and duplication of therapy 58 (1.6%). There was a total of 6,306 medication discrepancies of any kind; an average of approximately 2 per encounter. Top 5 therapeutic classes/ disease state involved were: Cardiovascular 1178 (18.6%), psychiatry/neurology 851 (13.5%), pain management 587 (9.3%), diabetes 452 (7.2%) and asthma/chronic obstructive pulmonary disease 360 (5.7%). Other significant discrepancies were documented with antiplatelet 189, anticoagulants 105, anticonvulsants 60, antineoplastic agents 54 and immunosuppressant 22. Estimated cost avoidance of $1,361,000 based on the average cost of an adverse drug event and the probability of occurring.

Conclusion: Pharmacists working in the emergency department identified medication discrepancies in a timely manner, reducing potential medication adverse events, and expenditures.

Poster Title: Assessing appropriateness of parenteral anticoagulants in a large academic tertiary medical center

Primary Author: Sukaina Taqi, Nova Southeastern University, Florida; **Email:** st964@nova.edu

Additional Author (s):
Sinziana Ungureanu
Marta Miyares

Purpose: According to the Centers for Disease Control and Prevention, each year approximately 1 to 2 individuals in 1000 may be affected by venous thromboembolism (VTE). VTE consists of deep vein thrombosis and pulmonary embolism, both of which are correlated with morbidity and mortality. VTE prevention and treatment are quality measures set forth by The Joint Commission together with the Centers for Medicare & Medicaid. The objective of this study was to examine the utilization and appropriateness of fondaparinux and enoxaparin in patients with an indication for VTE.

Methods: This was a retrospective study of 91 patients who received fondaparinux from April 1 to August 20, 2016 or enoxaparin from August 1 to August 31, 2016. At this hospital, fondaparinux is restricted for use in patients who have heparin induced thrombocytopenia (HIT) while enoxaparin may be used when appropriate and at the prescriber's discretion. The data collected was examined for appropriateness based on indication, dosing, frequency, and transitioning to other anticoagulants based on the hospital's protocols as well as clinical guidelines. All institutional review board procedures were followed. Data was analyzed using descriptive statistics.

Results: From the 91 patients assessed, 70 percent received enoxaparin and 30 percent received fondaparinux. Sixty eight percent of patients were male, had an average age of 58 years, and an average weight of 82 kilograms. The primary indication for patients on enoxaparin was VTE treatment which accounted for 63 percent. The predominant indication for fondaparinux was HIT which equated to 93 percent. The majority of anticoagulant orders followed protocols based on weight and renal function. Furthermore, 2 percent of patients on enoxaparin and no patients on fondaparinux experienced episodes of bleeding. Appropriate

duration of overlap for warfarin bridging occurred in 48 percent of patients on enoxaparin and no patients on fondaparinux. Fifty three percent of patients who had not achieved therapeutic INRs did not have a concomitant parenteral anticoagulant documented upon discharge.

Conclusion: Based on these results, we conclude that increased monitoring of patients receiving parenteral anticoagulant therapy would be beneficial in order to ensure correct administration as well as appropriate transition between anticoagulants.

Submission Category: Practice Research/ Outcomes Research/ Pharmacoeconomics

Submission Type: Evaluative Study

Session-Board Number: 2-063

Poster Title: Measuring knowledge and attitudes regarding the use of pharmacogenetic testing among physicians

Primary Author: Suhaib Muflih, Nova Southeastern University, Florida; **Email:** sm2341@nova.edu

Additional Author (s):
Barry Bleidt
Nile Khanfar
Ioana Popovici

Purpose: Pharmacogenetic (PGx) testing is a relatively new field in medicine. It has become increasingly significant to enhance patient outcomes. Various studies have recognized the importance of pharmacogenetics in personalized medicine and how the adoption of this new innovation will potentially improve the safety and efficacy of medication use; however, there is a paucity of information about pharmacogenetic testing acceptance among physicians. The objective of this study is to identify and evaluate the impact of physicians' knowledge and attitudes on their adoption of PGx testing as a diagnostic tool in the current clinical settings.

Methods: Nova Southeastern University (NSU) physicians and community physicians (currently involved in medication therapy decisions for patients) were asked to complete an online survey. The survey collected data on socio-demographics, prior experience, perceived need for innovation, and rurality as independent variables related to knowledge about PGx testing. Similarly, relative advantage, compatibility, complexity, triability, and observability were the independent variables that were correlated with attitudes towards PGx testing. A statistical program was utilized to calculate sample size. Using a medium effect size and significance of 0.05, the minimum sample size was determined to be 120. The study protocol has been approved by the NSU's Institutional Review Board (IRB Protocol # 2016-77).

Results: 148 physicians (60 percent male, 40 percent female) from different specialties participated in the study. Nearly 29 percent indicated that they have no time to practice PGx testing. The majority of physicians were uninformed or not sure about the availability of PGx testing, FDA-approved medications with PGx information in their package inserts, and PGx

information in Plavix package insert (90 percent, 49 percent, and 55 percent, respectively). A large percentage of physicians expressed general agreement about the need for PGx testing in 3 specific situations (60.1 percent to 83.8 percent [Mean=74 percent]) and its relative advantage in also 3 specific situations (71.6 percent to 85.1 percent [Mean=80 percent]). Only 19.6 percent, 7.4 percent and 8.1 percent of physicians learned about genetics and genetic testing during their undergraduate courses, graduate school, and residency, respectively. The majority of physicians rated their level of knowledge about PGx testing to be poor, fair, or good (25 percent, 42 percent, and 23 percent, respectively). Only 58 percent of physicians would recommend PGx testing. Self-reported reasons for not ordering PGx testing were concerns about patients' confidentiality (26.7 percent), delay in treatment (40 percent), insurance coverage issues (46.7 percent), and clinical utility of the testing (53 percent).

Conclusion: Several factors influencing the implementation of PGx testing in clinical practice have been identified, including physicians' low familiarity with and lack of knowledge of PGx testing, and their concerns about the clinical utility of PGx testing, patients' confidentiality, and insurance coverage issues. As the number of available FDA-approved drugs with pharmacogenetic information increases, it would be helpful for physicians to receive additional continuing education and training in the field of pharmacogenetics. As such, medical students need to receive coursework in the field of pharmacogenetics so they can learn and develop the necessary skills to effectively implement PGx testing in practice.

Submission Category: General Clinical Practice

Submission Type: Descriptive Report

Session-Board Number: 2-064

Poster Title: Association of ACEI/ARB use on cardio-metabolic markers in the US Adult population

Primary Author: Renu Bala, Nova Southeastern University, Florida; **Email:** balare12@gmail.com

Additional Author (s):
Camala Murry
Mohadissa Suchedina
Neisha Williams

Purpose: Angiotensin converting enzyme inhibitors (ACEI) and Angiotensin receptor blockers (ARB) have been used in clinical practice primarily for their antihypertensive properties. However, there is conflicting evidence on their effects on body mass index (BMI), hemoglobin A1c (HbA1c), waist circumference and fasting blood glucose (FBG). The purpose of this study was to compare these biomarkers in non-diabetic individuals taking ACEI or ARB to those who are taking other antihypertensives excluding ACEI/ARB.

Methods: A secondary data analysis was performed using the cross sectional survey and physical examination from The National Health and Nutrition Examination Survey (NHANES) database which includes health and nutritional status of civilian, non-institutionalized US population. This study included nondiabetic adults with HbA1c < 6.5% who were ≥ 20 years of age who were on antihypertensive treatment at the time of survey screening. The sample was divided into two groups; individuals who were on ACEI or ARB monotherapy (treatment Group) and those on non ACEI/ARB antihypertensive treatment. All estimates are nationally representative of the civilian, non-institutionalized US adult population, meeting the study criteria and have been adjusted for confounding factors and non-response bias. Chi-square test was used to compare the differences in categorical variables such as socio-demographic data (race, age, education, gender and marital status); study outcomes including clinical parameters (FBG and HbA1c) and biometrics (BMI and waist circumference) across study groups. The independent t-test was used to compare outcome differences in average HbA1c, BMI, waist circumference, and average FBG. Data was described using mean, percentage and proportion as is appropriate. A significance level (alpha=0.05%) was used for all comparisons.

Results: Among the subjects included in the study (N=1480), 33% were on ACEI or ARB monotherapy. The majority of respondents were non-Hispanic white. Mean average age was lower in treatment group (58 years) compared to the non-ACEI/ARB group (61 years; $p < 0.05$). Both groups comprised of higher proportion of female individuals and with greater than high school level of education. Marital status showed no significant difference among both groups. Average HbA1c was lower in the treatment group (5.5%) compared to the non-ACEI/ARB group (5.6%; $p=0.047$). No significant difference was observed for average BMI, waist circumference and FBG.

Conclusion: Individuals who were taking ACEI or ARB had significantly lower HbA1c when compared to those who were taking non ACEI/ARB antihypertensive therapy. Considering the limitations of this research, this association could expand the role of ACEI or ARB in not only treating hypertension but reducing specific cardio-metabolic risk factors.

Submission Category: General Clinical Practice

Submission Type: Evaluative Study

Session-Board Number: 2-065

Poster Title: Importance of implementing genomic and pharmacogenomic testing by healthcare professionals

Primary Author: Zejna Custovic, Nova Southeastern University, Florida; **Email:** zc63@nova.edu

Additional Author (s):
Tiffany Harrison
Laura Saladrigas
Carly Weisser
Lynn Lafferty

Purpose: Pharmacogenomics is the study of how DNA can affect a person's response to their medication. Most medications are hepatically metabolized by the cytochrome P450 (CYP450) enzyme system. An example is clopidogrel, which is a pro-drug that utilizes CYP2C19 metabolism to convert into its active compound. Utilizing pharmacogenomic testing may identify the patients who are poor metabolizers of the drug and help physicians choose an optimal regimen in order to prevent a potential adverse event from occurring. The purpose of this study was to determine the opinions of various physicians on the topic of pharmacogenomic testing.

Methods: After researching case studies on the importance of pharmacogenomic testing, current available courses offered on pharmacogenetics, insurance information, and legal aspects, a physician survey was conducted. The Institutional Review Board approved a survey that was sent out to fourteen faculty physicians at the Nova Southeastern University College of Osteopathic Medicine in order to gauge their knowledge and utilization of pharmacogenomic tests. The survey focused specifically on CYP2C19 enzyme tests and was developed by referencing a survey that was developed for pharmacy students in Canada. The primary outcome of this assessment was to determine the level of knowledge practicing physicians have in regard to pharmacogenomics testing and how, and if, they apply the testing to their practice. Secondary outcomes included whether or not the practicing physicians would be interested in having a pharmacist help facilitate and read the tests and if they would like additional training in the subject through a continuing education course. The inclusion criteria for physicians to participate in the survey was to be a practicing physician who was faculty at the College of

Osteopathic Medicine. This was conducted as a pilot study in order to assess the results and eliminate any unsuccessful questions before sending it to a larger group of physicians. The survey is intended to be sent to a larger population in the future. Data was analyzed using descriptive statistics.

Results: Out of fourteen surveyed physicians, only three physicians (21.4 percent) were very informed on pharmacogenomic testing and currently utilize it in their practice; six physicians (42.9 percent) were somewhat informed on the field; five physicians (35.7 percent) were not informed at all and wished to expand their knowledge on the subject. The results of the survey demonstrated the need for healthcare professionals to be educated on pharmacogenomics and there is a drastic need to enable collaboration between pharmacists and physicians in order to increase treatment outcome.

Conclusion: There is a drastic need for healthcare professionals to be educated on pharmacogenomics and it is essential to enable collaboration between pharmacists and physicians in order to increase treatment outcomes and decrease adverse events from these medications and improve patient outcomes by individualizing therapy. Based on the survey results, physicians are interested in collaborating with pharmacists for the utilization of pharmacogenomic testing and would like to participate in a continuing education course to learn more about the benefits of this testing. Further surveying is necessary.

Submission Category: General Clinical Practice

Submission Type: Evaluative Study

Session-Board Number: 2-066

Poster Title: Belatacept versus tacrolimus as first line immunosuppression maintenance therapy in patients with renal transplant

Primary Author: Leroy Koh, Nova Southeastern University, Florida; **Email:** lk627@nova.edu

Additional Author (s):
Leanne Lai
Simon Leung
Teresamari Pastrana-camacho

Purpose: Belatacept is a novel immunosuppressive drug designed to minimize toxicities associated with calcineurin inhibitors (CNI) like cyclosporine and tacrolimus. Clinical trials had showed first line belatacept based therapy resulting in superior cardiovascular and renal safety profiles but did not compromise graft failure rates as compared to CNI based therapy in renal transplantation. In addition, belatacept was compared against cyclosporine, which is not widely adopted as the CNI of choice. Therefore, the purpose of this study was to compare the difference in the occurrence of graft failure between belatacept and tacrolimus when initiated as first line immunosuppression therapy in renal transplantation.

Methods: A retrospective cohort study was conducted using the Organ Procurement and Transplantation Network (OPTN) database. The OPTN database contains data regarding every organ transplant event occurring in the US since October 1987. The data is collected through collection forms completed by transplant professionals and submitted via an online web application. Inclusion criteria was all renal transplants completed between September 2011 and March 2015 and documented hospital discharge of either belatacept or tacrolimus as immunosuppression therapy. All patients had at least one year of follow up. Exclusion criteria was the transplants with incomplete data on any study measure such as graft failure or other covariates. Univariate analysis between graft failure as defined by OPTN and immunosuppression therapy used was conducted using Pearson Chi-Square. Multiple logistic regression was conducted to compare the occurrence of graft failure after adjusting for potential confounders. Two tailed statistic with p value less than 0.05 was considered statistically significant. All data analysis described was performed using Statistical Analysis System (SAS) software 9.4.

Results: A total of 55,884 renal transplant patients met the study criteria and received either belatacept or tacrolimus. Of which, 521 (0.9 percent) received belatacept and 55,363 (99.1 percent) received tacrolimus. The average age (years old) and body mass index (BMI, kilogram per meter squared) of those receiving belatacept versus tacrolimus were 53.4 plus minus 14.1 versus 49.8 plus minus 15.5 and 28.2 plus minus 5.0 versus 27.6 plus minus 5.6, respectively. Sixty-five percent of males made up those receiving belatacept as compared to 61.3 percent of those receiving tacrolimus. The results from the univariate odds ratio (OR) showed no significant difference in graft failure occurrence between belatacept and tacrolimus (OR equal 0.92, 95 percent confidence interval; 0.69, 1.23). Total days on kidney waiting list, recipient education level at transplant, recipient BMI, primary payment source, recipient functional status at transplant, recipient age, recipient diabetes status at transplant listing, previous malignancy, recipient ethnicity, recipient gender and recipient serum creatinine level at discharge were included into the multiple logistic regression as covariates. After adjusting for potential confounders, the final multiple logistic model still did not show significant difference in the two treatment groups (adjusted OR equal 0.96, 95 percent confidence interval; 0.72, 1.28).

Conclusion: This study is one of few real world observational studies that compared the clinical effects between belatacept and tacrolimus as first line immunosuppression therapy. No significant difference in graft failure occurrence was seen between the two comparators, reinforcing the results of previously conducted clinical trials. It highlighted the potential role of belatacept to play a more important part in immunosuppression for renal transplant patients, as an alternative to the gold standard tacrolimus. Future analyses are needed to further assess the safety profile of belatacept.

Poster Title: InfaDose Pro: the ultimate dosing and over-the-counter medication guide for infants

Primary Author: Michelle Henninger, Nova Southeastern University College of Pharmacy, Florida; **Email:** mhenninger09@gmail.com

Additional Author (s):
Christina Llerena
Valerie Llerena
Vanessa Perez
Chloe Tamargo

Purpose: In the midst of complex over-the-counter products and ambiguous labels, children may be dosed inaccurately. Most products do not contain dosing information for children under the age of two. In fact, the most common medication errors in the outpatient pediatric population are due to dosing miscalculations. We designed a product, the InfaDose Pro, with the objective of reducing the risk of over-the-counter dosing errors in the infant population by providing parents with a reliable self-care resource. We modeled the product after the Broselow Tape, which has demonstrated value in preventing dosing errors in the emergency department setting.

Methods: There are about 1.5 million medication-related errors that occur each year of which, approximately one third are occurring in the outpatient setting. A further investigation was conducted by five researchers who found no evidence of a current product to address this need. As a result, interviews were conducted with the following potential stakeholders: consumers of childbearing age, pharmacists and pediatricians. After receiving suggestions and feedback, a prototype was created for an over-the-counter guide to aid parents. Inaccurate estimation of infant weight, can lead to dosing miscalculations. Thus, the researchers used the National Health and Nutrition Examination Survey to create a dosing measurement that accounted for the infant's potential weight. Using World Health Organization infant growth charts, estimated height and weights were calculated and recorded for infants under the age of two. Several sources were consulted to ensure accuracy of drug information and dosing. Doses were acquired and calculated primarily from The Pediatric & Neonatal Dosage Handbook.

Information was then cross referenced with the Handbook of Nonprescription Drugs to ensure safety of the product. Once doses were correct, appropriate, and safe; additional information regarding immunizations, vitamin use, diaper rash, and dosing techniques were collected. The additional information was obtained from the following resources: Center for Disease Control and Prevention immunization schedule, American Academy of Pediatrics, Journal of Clinical Medicine and the Pediatric Dermatology Handbook.

Results: The InfaDose Pro contains the most commonly misused over-the-counter products to treat infants such as acetaminophen, diphenhydramine, and ibuprofen. Additionally, it contains information on common concerns with newborn parents such as immunizations, diaper rash, and vitamins. The product was designed to be portable, educational and user-friendly. It is a double-sided, accordion dosing guide indicated for infants ages two and below which unfolds to approximately 47 inches or 120 centimeters long. Similar to the Broselow tape, the product includes color-coded weight brackets to correspond to an approximate dose for each medication. However, unlike the Broselow tape, which is used for emergency medications, the InfaDose Pro contains information regarding over-the-counter medications. The front side of the InfaDose Pro includes the color-coded measuring guide, along with appropriate estimations for previously mentioned medications. The back side of the InfaDose Pro, contains information on common concerns with newborn parents such as immunizations, diaper rash, and vitamins. Parents will use the InfaDose Pro to measure their infant's height and match it with the appropriate color bracket to estimate their weight. Once the appropriate color is identified, the dose is provided in milliliters and milligrams. Proper administration technique is on the guide to prevent dosing errors.

Conclusion: Eighty-five percent of parents in the United States treat their children with over-the-counter medications before seeking professional care. Pharmacists are the most accessible health-care professional and are responsible for the safety of the community. The InfaDose Pro was designed to address arising issues such as low health literacy and numeracy skills among the general public. The InfaDose Pro has the ability to ensure that parents are dosing their children correctly, thus reducing morbidity and mortality due to dosing errors.

Poster Title: Association of metformin use and vitamin B12 deficiency, peripheral neuropathy, and cognitive impairment in elderly patients with type 2 diabetes

Primary Author: Gabrielle Vaz, Nova Southeastern University College of Pharmacy, Florida; **Email:** gv178@nova.edu

Additional Author (s):
Damien Alpizar
Erin Scarpinato
Alexandra Perez
Lazara Cabrera Ricabal

Purpose: Metformin is a commonly prescribed medication to treat type 2 diabetes mellitus that has been associated with vitamin B12 deficiency in various studies. Vitamin B12 is involved in neurologic processes and deficiency may contribute to cognitive decline and neuropathic pain. The geriatric diabetic population is at a higher risk for these conditions. The primary objective of this study is to determine the association of metformin use with the presence of vitamin B12 deficiency in adults ages 65 or older with type 2 diabetes mellitus. Secondary objectives included determining if there were more peripheral neuropathy or cognitive impairment with metformin use.

Methods: Data were taken from the National Health and Nutrition Examination Survey (NHANES) using 3 cohorts spanning from 2001-2012. The inclusion criteria for this study were individuals who were ≥ 65 at the time of the NHANES survey screening and were diagnosed with type 2 diabetes mellitus by age ≥ 20. The sample was divided in two study groups: those on metformin and those that were not on metformin. Age, gender, race, household income, level of education, health insurance coverage, and HbA1c were among the descriptors used for sample characteristics. Three outcomes were evaluated: vitamin B12 deficiency (levels < 200ng/mL as a dichotomous variable), vitamin B12 average levels, cognitive decline, and peripheral neuropathy. NHANES data did not have a direct assessment for cognitive decline or peripheral neuropathy therefore use of acetylcholinesterase inhibitors, and pregabalin and gabapentin were used as surrogate markers for these outcomes, respectively. Mean, standard deviation, and percent (frequency) were used to quantify the data. Chi-square and independent

t-test statistical analysis were performed using IBM SPSS version 24 to determine significant differences among the two study groups. An alpha level of 5% was used in this study. Data have been adjusted for complex sample design and non-response bias. The data have been standardized to be representative of the national population.

Results: The study included a total of 491 patients. There were 315 patients in the non-metformin group, and 176 were in the metformin group. The mean age for patients in the non-metformin study group (74.55 +/- 6.094) was significantly higher than those in the metformin study group (72.9 +/- 5.2, p=0.003). The race distribution was significantly different across groups (p=0.031). The HbA1c values were not significantly different between the two groups. All other sample descriptives were the same between the two study groups (p>0.05). Average vitamin B12 levels (metformin 563.9 +/- 35.4 pg/mL; non-metformin 665.6 +/- 43.1 pg/mL; p=0.0018) were significantly lower in the metformin group. The proportion of Vitamin B12 deficiency (metformin 6.7%; non-metformin 4.0%; p-value=0.192) were not significantly different but were lower for the non-metformin group. Use of acetylcholinesterase inhibitors (metformin 1.7%; non-metformin 0.7%; p=0.219), and neuropathic pain medications (metformin 6.7%; non-metformin 5.6%; p= 0.818) was not significantly different.

Conclusion: While study limitations prevent determination of a causal relationship, there was an association found between lower B12 values and metformin use. Additional prospective research is needed to look at the duration of metformin therapy and the trends of B12 levels as this will provide useful clinical information regarding the use of metformin in patients. No significant association was found between the surrogate markers for peripheral neuropathy and cognitive decline in patients on metformin.

Submission Category: Geriatrics

Submission Type: Evaluative Study

Session-Board Number: 2-069

Poster Title: Use of select Beers list medications in white, black, and Mexican American geriatric patients

Primary Author: Abigail Narens, Nova Southeastern University College of Pharmacy, Florida; **Email:** an494@nova.edu

Additional Author (s):
Yulia Rybalka
Alexandra Perez Rivera
Richard Finkel

Purpose: One-third of all medications prescribed to the elderly may trigger serious adverse effects such as falls, hip fractures, or excess sedation, thus resulting in a lower quality of life and increased healthcare costs. The Beers drug list compiles medications that are potentially inappropriate for the geriatric population. While a few studies have quantified their use none have evaluated whether there are differences across race/ethnic groups in the United States. The objective of this study was to compare the use of commonly prescribed medications meeting Beers criteria across geriatric patients self-reporting as white, black, or Mexican-American.

Methods: This was a secondary database analysis using data from the National Health and Nutrition Examination Survey (NHANES) 2005-2012 cohorts. NHANES samples approximately 5,000 non-institutionalized U.S. civilians yearly through a series of cross-sectional studies comprising interviews and physical examinations. Subjects were included in the study if they were 65 years of age or older at the time of survey interview and who self-reported to be non-Hispanic white, non-Hispanic black, or Mexican-American. The main outcome was being on either long-acting benzodiazepines including clorazepate, chlordiazepoxide, clidinium-chlordiazepoxide, clonazepam, diazepam, flurazepam, and quazepam, the barbiturate agent butalbital, or pain medications such as meperidine and ketorolac. Sociodemographic, clinical, and medication and outcome data were compared across race/ethnic groups using chi-square and one-way analysis of variance (ANOVA) tests for categorical and continuous variables, respectively (alpha= 0.05). IBM SPSS Version 22 was used to conduct data manipulation and analysis. This study was exempt from institutional review board (IRB) review.

Results: Among the 4770 patients meeting inclusion criteria, the mean age was 73 (range: 72-75 across race/ethnic groups). Whites were more likely to be older and have higher income, show better renal function and were more likely to have 4 or more hip fractures than blacks and Mexican Americans ($p < 0.05$). Use of select Beers list drugs was low overall but significantly different across race/ethnic groups ($p < 0.011$). Use among whites was 2% (n=62), and 1.1% (n=10) and 0.5% (n=3) for blacks and Mexican Americans, respectively. Among those taking a Beers list drug, all (100%) were taking only one medication of interest. Clonazepam was the most used medication (0.84%, n=40) followed by diazepam (0.46%, n=22), chlordiazepoxide (0.15%, 7), clorazepate (0.10%, 5) and ketorolac (0.02%, 1). None were taking the other Beers drugs of interest.

Conclusion: Results indicated that the overall use of select Beers list drugs among a sample of geriatric patients was low but should ideally be zero. We also found their use to be highest in the non-Hispanic white group which was the most affluent group. Prescribers must be aware of the dangers of using these medications in a frail population and how it may be different across race/ethnic groups.

Submission Category: Infectious Diseases

Submission Type: Descriptive Report

Session-Board Number: 2-070

Poster Title: Review of tenofovir/emtricitabine for HIV pre-exposure prophylaxis in adolescent patients

Primary Author: Kamarena Sankar, Nova Southeastern University College of Pharmacy, Florida; **Email:** ks1064@nova.edu

Additional Author (s):
Saba Mahdavi
Elizabeth Sherman
Nathan Unger

Purpose: According to Centers for Disease Control and Prevention, in the United States in 2014, youth ages 13-23 accounted for 22% of new HIV diagnoses; as such, adolescents are a critical target to prevent the spread of HIV. Tenofovir/emtricitabine (TDF/FTC) is approved by the US Food and Drug Administration for use as pre-exposure prophylaxis (PrEP) in combination with safer sex practices to reduce the risk of sexually acquired HIV in high risk HIV-uninfected adults. When taken every day, PrEP reduces HIV infection in adults by more than 90%. While approved for adults, PrEP is not approved for use in adolescents.

Methods: To investigate efficacy and safety of PrEP use in HIV-uninfected adolescents, a literature review was conducted from inception through September 2016 in PubMed along with conference abstracts from International AIDS Society, Conference on Retroviruses and Opportunistic Infections, Infectious Disease Society of America, and International AIDS Conference. Terms used in the search included "PrEP," "pre exposure prophylaxis," "adolescents," "young adults," "TDF/FTC," "TDF", "tenofovir," "Truvada," and "uninfected."

Results: Two studies were identified on efficacy and safety of PrEP use in HIV-uninfected adolescents. The Plus Pills study followed 148 adolescents between 15-19 years of age (66% female, median 18) on PrEP with TDF/FTC for 12 weeks. At week 12, 72% of participants were adherent(pill count > 6 doses per week), and 76% were adherent (plasma TDF > 40 ng/mL). 15% of patients reported adverse effects, (mild headache and gastrointestinal side effects). No participants became infected with HIV during the study. 85% of patients continued PrEP after study conclusion. In the PrEPare (ATN 113) study, 79 adolescent men who have sex with men

(MSM) 15-17 years of age (mean 16.5) were provided PrEP with TDF/FTC and followed for 48 weeks. Adherence, defined by tenofovir level, was 60%(week 4), 55%(week 12), and dropped to 31.5%(week 24). Three participants (4%) seroconverted to HIV positive within the study, all with subtherapeutic tenofovir levels. The most serious adverse event attributed to use of TDF/FTC was weight loss of 10-19%, observed in 2.5% of patients. Compared to adherent subjects, non-adherent participants were more likely to cite concerns that others would think they are HIV-positive due to need to take pills (p = 0.03).

Conclusion: Use of PrEP in high risk adolescents appears safe and effective, however they should be monitored frequently to ensure adherence to optimize efficacy. Adherence was a key factor discussed in both studies, and in PrEPare in young MSM, when follow up frequency changed from monthly to every three months, PrEP adherence dropped over 20%. PrEPare found that youth need more frequent follow ups and supplemental reminders to enhance their adherence. Data on use of PrEP in adolescents for prevention of HIV infection is limited and additional studies should be conducted to illustrate its safety and efficacy specifically in this population.

Poster Title: Impact of monotherapy or combination use of antiarrhythmics and antimicrobials agents on hospitalization rates in adults.

Primary Author: Deandra Romero, Nova Southeastern University College of Pharmacy, Florida; **Email:** dr719@nova.edu

Additional Author (s):
Sose Tokatlian
Alexandra Perez
Nathan Unger

Purpose: Certain antiarrhythmic and antimicrobial agents have been linked with the potential of inducing QT prolongation. Consequently, some have been removed from the market or relabeled with warnings. However, there is a lack of quantifiable data measuring the association of these medications and hospitalization rates. There are case studies suggesting that the risk is minimal unless the individual has other risk factors. For example, electrolyte imbalance, increasing age, and concomitant QT prolonging medications. The purpose of this study is to assess the association of monotherapy or combination use of antiarrhythmics and antimicrobials agents on hospitalization rates in adults.

Methods: A secondary database analysis was conducted using cross-sectional data from the National Health and Nutrition Examination Survey (NHANES) database collected through interviews and surveys. Adults greater than or equal to 40 years of age from cohorts 2005 to 2006, 2007 to 2008, 2009 to 2010, and 2011 to 2012 were included in this study. Subjects were divided into two different study groups 1) subjects on either QT prolonging antiarrhythmics or antimicrobial agents, either as monotherapy or in combination and 2) subjects not on either medication class. Study outcomes included whether or not subjects were hospitalized and the number of annual hospitalizations visits. Results were generalized to the United States population. Descriptive and inferential statistics using chi-square and independent t-test analysis were performed using IBM SPSS statistics, version 24, to compare differences amongst the sociodemographic and hospitalization data across the two groups. Results were described using number (n), percent, means, and standard deviation where appropriate. An alpha level of 5 percent was used to determine significance.

Results: Of the 136,323,852 subjects included in the study, 878,388 were on QT prolonging antiarrhythmic or antimicrobial agents, as monotherapy or in combination, while 135,445,464 subjects were not on either medication class. The average age for those in the study group was 60.30 years in comparison to 57.29 years in the control group. Of the 878,388 subjects in the study group taking the specified medications, 44 percent were females. A higher prevalence of congestive heart failure, coronary heart disease, and other comorbidities was seen in the study group when compared to the control group. A statistical association was determined between QT prolonging antiarrhythmic and antimicrobial agents, either as monotherapy or in combination, and hospitalization rates. Specifically, yielding 203,095 (23.4 percent) hospitalizations and 16,799,509 (12.4 percent) hospitalizations in the study and control group, respectively (p equals 0.012). Furthermore, there was also clinical significance in the number of annual hospitalization visits, where the study group had more reoccurring hospitalizations in comparison to the control group despite there being no statistical significance (p equals 0.408).

Conclusion: Antiarrhythmic and antimicrobial use as monotherapy or in combination was significantly associated with hospitalization rates. Subjects were twice as likely to be hospitalized compared to those not on either medication class. There was no significant association with the number of annual hospitalization visits. Limitations included the inability to establish a direct temporal cause and effect relationship due to it being a cross-sectional analysis. Others include, potential for self-report bias, QT prolonging risk factors or comorbidities that were not controlled for, and reasoning behind hospitalizations being unknown. This study opens room for future studies on drug-induced QT prolongation.

Poster Title: Evaluating costs of influenza vaccines and the incentives offered for cash paying consumers at community pharmacies

Primary Author: Adam Steinberg, Nova Southeastern University College of Pharmacy, Florida; **Email:** as2726@nova.edu

Additional Author (s):
Eduardo Guizan
Dayana Martinez
Julio Simon
Lazara Cabrera Ricabal

Purpose: Currently, 11.5 percent of the United States adult population is uninsured. Average annual influenza complications have been attributed to approximately 2.5 million outpatient visits, 32,000 hospitalizations, and 680 deaths among adults. Lack of coverage may pose a significant barrier to influenza vaccination. For cash paying consumers, the cost and array of incentives to receive an influenza vaccination varies by pharmacy. Pharmacists providing medication therapy management services may find it difficult to provide information regarding the most cost effective influenza vaccination. Therefore, the primary objective was to investigate the cost of influenza vaccines and incentives offered by traditional and non-traditional pharmacies.

Methods: Online searches were conducted and data for influenza vaccine ("flu shot") costs were pulled from multiple pharmacy websites and/or online resources. Inclusion criteria included four traditional chain pharmacies (i.e., CVS, Navarro, Target-CVS, Walgreens) and six non-traditional pharmacies, located in supermarkets, big box department stores, or membership-only warehouse clubs (i.e., Costco, K-Mart, Publix, Sam's Club, Walmart, Winn-Dixie) common in south Florida. The costs of three different inactivated influenza vaccine formulations (two trivalent and one quadrivalent) offered from the various pharmacies were included. We excluded Fluzone High-Dose since this is reserved for older adults who may be receiving government coverage (e.g., Medicare). Various incentive programs were also included and evaluated for the aforementioned pharmacies and used to determine the most cost effective vaccine(s) offered. Descriptive statistics were used to evaluate the data.

Results: The cost of Fluvirin, a trivalent influenza vaccine, had the lowest price at an average of $21.25 and was available at four pharmacies. There are no incentives offered by Costco or Sam's Club but Fluvirin had the lowest cost at $14.99 and $20, respectively. Winn Dixie charges $25 for Fluvirin but offers a free "flu shot" on certain weeks, if the customer purchases $50 worth of groceries. Walgreens charges $32 for Fluvirin but may be reduced to $25 if the customer is a member of the Prescription Savings Club (PSC), which costs $20 a year. Afluria, a trivalent influenza vaccine, had an average cost of $30 and was available at three pharmacies. Publix and Walmart did not offer incentives; however, K-Mart offers $10 in reward points if a person fills 5 prescriptions at the pharmacy ("flu shots" count towards this prescription fill count). Fluarix was the only quadrivalent vaccine formulation offered by five pharmacies at an average cost of $38. However, Sam's Club offered Fluarix at $30 making it the lowest priced among the pharmacies evaluated. Overall, 40 percent of the pharmacies offered some form of incentive for consumers ranging from 20 percent off store coupons to $5 gift cards.

Conclusion: Many Americans are without coverage and may not be able to afford influenza vaccination. At this time, cash paying consumers may find their best option for influenza vaccination is Costco. Despite being a membership-only warehouse club, Costco does not restrict public access to their pharmacies and a non-member can simply approach the pharmacy and pay $15 for a "flu shot". Winn Dixie may be a better option only if the weekly special of spending $50 on groceries to receive a free "flu shot" is available and the consumer is willing to purchase this amount of goods from the store.

Poster Title: Outcomes of counseling patients with chronic obstructive pulmonary disease as part of a new transition of care program

Primary Author: Cindy Cuello, Nova Southeastern University College of Pharmacy, Florida; **Email:** cc2331@nova.edu

Additional Author (s):
Emison Contreras
Marlene Delavalle

Purpose: Patients with Chronic Obstructive Pulmonary Disease (COPD) are at a higher risk for hospital readmission which, in turn, increases the risk of mortality. One of the principal causes of readmission is medication non-adherence. Identifying the key healthcare barriers such as socioeconomic status, language, and literacy are also vital. This program seeks to assess if patients with COPD can benefit from transitional care counseling and help decrease the rate of readmission.

Methods: University of Miami Hospital is a 560-bed academic teaching hospital. This review has been submitted to the hospital's IRB. Patients were identified as having COPD by case managers who would then communicate a daily list to the multidisciplinary team. During the month of July 2016, patients were counseled for an average of 3 days. Fourth year pharmacy interns assessed home medications, health care barriers, current adherence, provided side effect counseling for new medications, and discharge counseling. A health confidence screening tool was used to assess patient's adherence and knowledge upon first encounter and at discharge. Based on the patient's knowledge and adherence to medications, a self-rated score was provided then utilized by the intern to facilitate which points to target during counseling. These scores, together with readmission data, were reviewed to determine potential impact of pharmacy involvement in patients with COPD.

Results: A sample size of n=19 consisted of patients with a diagnosis for COPD. Using a health confidence screening tool, the average patient baseline score upon admission was 5.21. Upon discharge, the health confidence average score was 6.89. Patients with a baseline score less than 5 were classified as high risk. Approximately, there was an increase in 1.68 points in

patients confidence score. UMH readmission data was collected a month prior and one month after the pilot program began, to serve as a comparison tool for the program outcome. The July readmission number was 7 patients and for August the readmission number was 3 patients.

Conclusion: On average, the health confidence screening score of patients increased by 1.68 points when comparing their baseline and discharge score. Effective use of patient medication, disease counseling in COPD patients, and other multidisciplinary efforts resulted in a 42.85% decrease in hospital readmission one month after beginning the program. COPD transitional care counseling is an effective tool that can used to reduce the rate of readmission and increase therapy adherence for this patient population.

Poster Title: Exploring the dual doctor of pharmacy/physician assistant degree: comparison and assessment of curricula

Primary Author: Danny Dinh, Nova Southeastern University, College of Pharmacy, Florida;
Email: dd1320@nova.edu

Additional Author (s):
Alexa Vyain
John Rafalko
Jenny DeRose
Joshua Caballero

Purpose: The movement for pharmacists' ability to prescribe has been met with resistance at varying levels. Several Doctor of Pharmacy (PharmD) programs offer varying forms of dual degrees. A dual PharmD/Physician Assistant (PA) degree may be beneficial to obtain prescriber status. Traditionally, PA programs range between 2-3 years and grant graduates prescribing authority as established providers. While one program offers a five-year dual PharmD/PA degree, not all pharmacy programs possess the same infrastructure. The objective of this study was to assess curricula between PharmD and PA programs. Secondary objectives were to identify opportunities for tailoring curricula for dual PharmD/PA degrees.

Methods: The 2016 US News and World Report top 25 ranked PharmD and PA programs were included. The authors reviewed program websites including course syllabi and descriptions. Authors independently identified course credit hours dedicated to pharmacology, pharmacotherapy, physical assessment, diagnosis, and clinical rotations. Data were reviewed by a secondary author (e.g., PA faculty member for PA programs) for accuracy. Schools without specific descriptions or lack of data were excluded. Descriptive statistics and independent t-test ($p < 0.05$) were performed.

Results: Twenty nine PharmD and 23 PA programs were included. PharmD curricula averaged a total of 151.3 credits vs. 123.4 credits for PA curricula ($p < 0.01$). Pharmacology credit hours were statistically greater for PharmD curricula (12.8 vs 4.3, $p < 0.01$). Physical assessment credit hours (6.1 vs 0.9, $p < 0.01$) and diagnosis credit hours (4.1 vs. 0, $p < 0.01$) were significantly

greater for PA curricula. Clinical rotation credit hours were also statistically greater for PA curricula (45.9 vs. 40.5, p< 0.044). Of note, average elective credit hours for PharmD curricula were 8.96 (± 4.8).

Conclusion: PA curricula appear to have an additional 10.2 credit hours of physical assessment and diagnosis combined. While the average PharmD curriculum has approximately one hour of physical assessment, the nine hours of elective credit hours may be utilized for physical assessment and diagnosis. Additional clinical rotation credit hours may be needed or clinical rotations modified to fulfill both accrediting body requirements. Study limitations include the lack of analysis of all existing programs and overall different focuses of the curricula. However, these data serve as a starting point for discussion into dual degree options and offering pharmacists the opportunity to prescribe.

Poster Title: Lumacaftor and ivacaftor for the treatment of cystic fibrosis in patients with homozygous F508del mutation.

Primary Author: Patricia Gonzalez-Abreu, Palm Beach Atlantic University, Florida; **Email:** patricia_gonzalez-abreu@pba.edu

Additional Author (s):
Andrea Mezentsef
Jennifer Mijares
Shara Parrish

Purpose: To evaluate the efficacy of the combination therapy of lumacaftor with ivacaftor at week 24 in participants aged 12 years and over with cystic fibrosis who are homozygous for the F508del mutation.

Methods: Two phase 3, randomized, double-blind, placebo-controlled clinical trials were conducted to assess the effects of therapy of lumacaftor in combination with ivacaftor. Both drugs work on the cystic fibrosis transmembrane regulator, lumacaftor works as a corrector and ivacaftor as a potentiator. The population on both trials consisted of patients 12 years of age or older who had cystic fibrosis and were also homozygous for the F508del mutation in the cystic fibrosis transmembrane regulator. In both studies, patients were randomly assigned to receive a 24 weeks treatment. Treatments consisted of 3 arms, either lumacaftor at doses of 600 mg daily or 400 mg twice a day, in combination with ivacaftor 250 mg every 12 hours, or a matched placebo pill. The primary objective of the trials was the absolute change from baseline in the percentage of predicted forced expiratory volume in 1 second (FEV1) at week 24. Secondary outcomes included, absolute change from baseline in body mass index (BMI), absolute change from baseline in Cystic Fibrosis Questionnaire-Revised (CFQ-R), respiratory score, and number of pulmonary exacerbations.

Results: A total of 1,122 patients, 553 from TRANSPORT trial and 559 from TRANSIT trial, were randomized to receive study drugs. The mean baseline FEV1 was 61% of the predicted value. In both studies, there were significant improvements in the primary end point in both lumacaftor–ivacaftor dose groups. In both studies, FEV1 improvements were observed as early as day 15

and were sustained through 24 weeks in both lumacaftor–ivacaftor dose groups. The difference between active treatment and placebo with respect to the mean absolute improvement in the percentage of predicted FEV1 ranged from 2.6 to 4.0 percentage points (P < 0.001). Pooled analyses showed that the rate of pulmonary exacerbations was 30 to 39% lower in the lumacaftor–ivacaftor groups than in the placebo group. The rate of events leading to hospitalization or the use of intravenous antibiotics was lower in the lumacaftor–ivacaftor groups as well. The incidence of adverse events was generally similar between the lumacaftor–ivacaftor and placebo groups. Finally, the rate of discontinuation due to an adverse event was 4.2% among patients who received lumacaftor–ivacaftor versus 1.6% among those who received placebo.

Conclusion: Both TRANSPORT and TRANSIT clinical trials show evidence that lumacaftor in combination with ivacaftor provided a benefit for patients with cystic fibrosis homozygous for the F508del CFTR mutation. Combination therapy with lumacaftor–ivacaftor has shown to improve FEV1, decrease pulmonary exacerbations and hospitalizations, as well as an improvement in patient's IBM in patients who suffer from cystic fibrosis.

Poster Title: Effect of heart rate reduction on outcomes in heart failure using ivabradine

Primary Author: Lisa Mella, Palm Beach Atlantic University, Florida; **Email:** lmella188@gmail.com

Additional Author (s):
Natalie Mella
David Dakwa

Purpose: Chronic heart failure is a disease associated with high morbidity and mortality. Elevated resting heart rate is a known risk factor for adverse outcomes in heart failure. Despite the mortality and morbidity benefit with beta blocker use in heart failure patients, a majority of patients in clinical practice are below the therapeutic beta blocker target dose thereby, limiting their beneficial effects. The purpose of this study was to assess the effect of heart rate reduction on outcomes in heart failure with the use of the selective sinus-node inhibitor, ivabradine.

Methods: The institutional review board approved this randomized, double-blind, placebo-controlled, parallel-group study. Patients 18 years and older were eligible if they had symptomatic heart failure and left-ventricular ejection fraction of 35 percent or lower, in normal sinus rhythm with a heart rate of 70 beats per minute or greater, previously hospitalized for heart failure within the previous year, and on stable background maintenance therapy including a beta blocker if tolerated. Those with congenital heart disease, recent myocardial infarction, atrial fibrillation, and symptomatic hypotension were excluded. Patients were randomly assigned to receive ivabradine titrated to a maximum of 7.5 mg twice daily or placebo. A total of 3268 patients were randomly assigned ivabradine and 3290 received placebo. The primary endpoint was the composite of cardiovascular death or hospitalization for worsening heart failure. Secondary endpoint was the composite of cardiovascular death or hospitalization for worsening heart failure for patients receiving at least 50 percent of target daily dose of a beta blocker. It was determined that 1600 first events were needed to provide 90 percent power with a treatment effect of 15 percent relative risk reduction for ivabradine. Time-to-event curves were estimated using the Kaplan-Meier method. A Cox proportional-hazards model was used to estimate the treatment effect.

Results: The major finding of this study showed 24 percent of patients receiving ivabradine and 29 percent of those taking placebo had a primary endpoint event (hazard ratio 0.82, 95 percent CI, 0.75 to 0.90, P less than 0.0001). The primary effects were mainly hospitalization and death due to heart failure, with 21 percent in the placebo group versus 16 percent in the ivabradine group (hazard ratio 0.74, 0.66 to 0.83, P less than 0.0001). There was no difference in cardiovascular deaths between groups, however deaths due to heart failure was significantly reduced (hazard ratio 0.74, 95 percent CI, 0.58 to 0.94, P is equal to 0.014). Serious adverse events were more frequently associated with the placebo group versus the ivabradine group (P is equal to 0.025). Five percent of patients in the ivabradine group had symptomatic bradycardia compared with 1 percent in the ivabradine group (P is less than 0.0001). Visual side effects were more frequently reported in the ivabradine group than placebo (3 percent versus 1 percent, P is less than 0.0001).

Conclusion: Study results support the use of ivabradine for the reduction of cardiovascular events or hospitalization for worsening heart failure. Ivabradine is a well-tolerated and safe add-on treatment for stable and symptomatic heart failure patients with a heart rate of 70 beats per minute or greater despite optimized heart failure therapy with a beta blocker, angiotensin converting enzyme inhibitor and aldosterone antagonist.

Poster Title: Successful Strategies of Maintaining a Mentorship Program for Pharmacy Students

Primary Author: Jocelyn Freimuth, Palm Beach Atlantic University, Florida; **Email:** jocelyn_freimuth@pba.edu

Additional Author (s):
Adam Remick
Barbara Kelly

Purpose: Most students feel there is a need for a mentor, but do not know how to initiate a relationship within the pharmacy field. Realizing the need for pharmacy mentors, a program was initiated of faculty and alumni members of Palm Beach Atlantic University to mentor students. The Mentor Match Program was started and is being developed to serve as a beneficial connection between the two parties.

Methods: This research took place from September 2013 –April 2016. A preliminary survey was given in September of 2014 and 2015 to the P2 students from the classes of 2016 and 2017 of Palm Beach Atlantic University. One hundred eleven students chose to participate and filled out a survey consisting of methods students used to contact mentors. Students who did not have contact with their assigned mentor were excluded from the study. After evaluation, the students were then matched, based on the results, with faculty and alumni in similar interests. A notification of contact information was given to each mentee and instructed to contact their mentor with their CV to start their relationship. Mentors were instructed to guide the mentee in their needs. A follow-up survey was given in April 2016 to reassess the relationship.

Results: There was 65% success rate of maintaining a mentor-mentee relationship when having at least 2 different means of contact. When only a single mean of contact was used, only 24% of relationships lasted after in as little as a year. Electronic communication, which included social media and email, had the lowest success rate of only 32% compared to face-to-face and verbal contact of 68%. The Mentor Match program most commonly allowed students to have guidance in jobs, curriculum vitae assistance, residency assistance, and future career plans. Alumni mentors have shown to have more of a lasting relationship over time than faculty mentors.

Conclusion: Providing pharmacy students with a matched mentor had most success in maintaining a relationship by using more than one mean of contact. Despite the growth of social media relationships, face-to-face and verbal contact was still shown to be more successful for the student's relationship. As the program grew, alumni who chose to be mentors allowed the students a more diverse group of mentors, aside from faculty members, which led to more information being discussed and longevity of the relationship. In the future, a goal of growing the program of alumni would allow for more targeted matches and even more opportunities.

Poster Title: Cardiovascular outcomes of semaglutide in patients with type 2 diabetes

Primary Author: Natalie Mella, Palm Beach Atlantic University, Florida; **Email:** n.mella@aol.com

Additional Author (s):
Lisa Mella
Stacy Tran

Purpose: Cardiovascular disease is associated with high morbidity and mortality in patients with type 2 diabetes. The use of glucagon-like peptide 1 analogue, liraglutide, showed improved cardiovascular outcomes in type 2 diabetes patients. The purpose of this study was to evaluate the cardiovascular safety of glucagon-like peptide analogue, semaglutide, for the treatment of type 2 diabetes, which was shown to have an extended half-life of approximately one week.

Methods: The institutional review board approved this randomized, double-blind, placebo-controlled, parallel-group study. Eligible patients included those with type 2 diabetes and a glycated hemoglobin level of 7 percent or greater, with or without previous antihyperglycemic treatment or received treatment with no more than two oral antihyperglycemic agents, with or without basal or premixed insulin. Patients included were aged 50 years or older with established cardiovascular disease, chronic heart failure, chronic kidney disease, or aged greater than 60 with at least one cardiovascular risk factor. A total of 3297 patients with type 2 diabetes were randomized in a 1:1:1:1 ratio received either 0.5 mg or 1.0 mg of once-weekly subcutaneous semaglutide or placebo for 104 weeks, with a 5-week follow-up period. The primary composite outcome was the first occurrence of death from cardiovascular causes, nonfatal myocardial infarction or nonfatal stroke. The primary hypothesis was for non-inferiority for the primary outcome. The non-inferiority margin was 1.8 for the upper boundary of the 95 percent confidence interval of the hazard ratio. It was determined that 3260 patients were required to provide a power of 90 percent to reject a hazard ratio of at least 1.80 at a pre-specified 0.05 level of significance.

Results: The primary composite outcome occurred in 6.6 percent (108 of 1648 patients) in semaglutide group versus 8.9 percent (146 of 1649 patients) in the placebo group (hazard ratio 0.74, 95 percent CI, 0.58 to 0.95, P is less than 0.001 for non-inferiority). Nonfatal myocardial

infarction occurred in 2.9 percent (47 patients) in semaglutide group versus 3.9% (64 patients) in placebo group (hazard ratio 0.74, 95 percent CI, 0.51 to 1.08, P equals 0.12). Nonfatal stroke occurred in 1.6 percent (27 patients) in semaglutide versus 2.7 percent (44 patients) in placebo group. The rate of cardiovascular death reported was 2.7 percent (44 patients) in the semaglutide group versus 2.8% (46 patients) in the placebo group (hazard ratio 0.98, 95 percent CI, 0.65 to 1.48, P equals 0.92). Adverse events associated with semaglutide use included gastrointestinal side effects such as nausea, vomiting and diarrhea.

Conclusion: The study results concluded that semaglutide had significantly lower rate of cardiovascular death, nonfatal myocardial infarction, or nonfatal stroke than patients receiving placebo with high cardiovascular risk. The risk reduction observed was similar with both doses of semaglutide. In addition, the study concluded that semaglutide was statistically noninferior to placebo for the rate of cardiovascular death.

Poster Title: The use of monoclonal antibodies for the prevention of recurrent Clostridium difficile infection: a systematic review of the use of bezlotoxumab.

Primary Author: Andrea Mezentsef, Palm Beach Atlantic University, Florida; **Email:** andrea_mezentsef@pba.edu

Additional Author (s):
Patricia Gonzalez-Abreu
Doaa Alkiswany

Purpose: To evaluate the efficacy and safety of bezlotoxumab for the prevention of CDI recurrence during the 12-week (day 85 ± 5 days) follow-up period after a clinical cure of the baseline CDI episode was established.

Methods: The terms "bezlotoxumab", "MK 6072", "Clostridium difficile" and "Clostridium difficile toxin B monoclonal antibody" were utilized to conduct a systematic literature search using PubMed, OVID MEDLINE, FDA.gov and ClinicalTrials.gov. Two phase III trials were found (P001 and P002), reviewed and evaluated.

Results: The P001 and P002 studies were randomized, multicenter, double-blind, placebo-controlled trials. Safety and efficacy of bezlotoxumab was observed in 2,655 participants assigned to receive actoxumab+bezlotoxumab, bezlotoxumab, actoxumab or placebo.
The primary efficacy objective in both studies was whether or not treatment with one single infusion of one or both of the individual mAbs given with SOC antimicrobials decreased CDI recurrence vs placebo and SOC therapy alone during the 12-week study period. In Study P001, the proportion of patients who experienced CDI recurrence was significantly lower in the actoxumab+bezlotoxumab group (15.9%) vs placebo (27.6%). The adjusted differences in CDI recurrence between actoxumab+bezlotoxumab and placebo were −11.6% (95% CI, −17.3% to −5.9%) and −10.1% (95% CI, −15.9% to −4.3%) between bezlotoxumab and placebo.
In Study P002, the proportion of patients who experienced CDI recurrence was significantly lower in the actoxumab+bezlotoxumab group (14.9%) and the bezlotoxumab group (15.7%) vs placebo (25.7%). The adjusted differences in CDI recurrence between actoxumab+bezlotoxumab and placebo was −10.7% (95% CI, −16.3% to -5.1%), and −9.9% (95%

CI, −15.5% to −4.2%) between bezlotoxumab and placebo. In regards to safety, < 1% of patients discontinued treatment due to the adverse effects. Commonly reported ADRs included nausea, diarrhea, headache and fever.

Conclusion: Bezlotoxumab has the potential of being the first monoclonal antibody indicated to prevent the recurrence of CDI, but approval from the FDA is currently pending. More studies need to be performed in order to prove bezlotoxumab's efficacy since additional data was requested by the FDA, resulting in the delay of bezlotoxumab's approval. An extension of the Prescription Drug User Fee Act (PDUFA) goal was given with an expected response date of three months. The assigned new goal date for review of supporting data will be on October 23, 2016.

Poster Title: Analysis of Clostridium difficile infections in a community health-system

Primary Author: Adam Remick, Palm Beach Atlantic University - Gregory School of Pharmacy, Florida; **Email:** adam.remick@gmail.com

Additional Author (s):
Abel Carranza
Aileen Martinez

Purpose: Clostridium difficile infections CDI remain a predominant problem in healthcare, despite precautions used to prevent contamination. Several contributing factors may include employee hygiene, visitor hygiene, or medications used that could increase risk of acquiring a CDI. Previous studies have shown an increase of CDI due to certain antibiotics used compared to others, as well as usage of gastric suppressing agents, particularly proton pump inhibitors (PPI). The purpose of this study is to analyze patients with CDI at Martin Health System.

Methods: Following Institutional Review Board (IRB) approval, a retrospective chart review was performed on patients who were tested positive for CDI from July 1, 2015 to July 1, 2016. A positive result for CDI was defined as a positive test for C. difficile toxin tested by in house microbiology lab. The primary outcomes include rates of infection related to antibiotic use, rates of infection related to certain antibiotic use, and rates of infection related to gastric suppression use. Secondary outcomes included antibiotics used to treat CDI infection and infection severity of the patient. Severity was calculated using the CDI severity index (CSI). End points were collected from the electronic medical record. The data collected included: patient age, gender, infection after admission (days), antibiotic usage within hospital for >3 days, which antibiotic was used for non-C. difficile treatment (if applicable) and duration, gastric acid suppression usage, white blood cell count, albumin level, temperature, C. difficile treatment and duration, and mortality. Following completion of data collection, all patient identifiers were removed. Descriptive statistics were utilized to assess results of the study.

Results: Over 22% of patients who were admitted > 3 days prior of C. difficile testing were taking antibiotic. For admitted patients, the percentages of the most common class of antibiotics taking by patients implicated for C. difficile were fluoroquinolones and

cephalosporins which accounted for a combined total of 66% (33% each). Among the fluoroquinolones, levofloxacin was the most prescribed.

Over 36% of patients were taking antibiotics 1 month prior to hospital admission. For individuals who were taking antibiotics 1 month prior of being admitted, fluoroquinolones were the largest antibiotic class implicated for C. difficile accounting for 31%, followed by cephalosporins accounting for 24%. Ciprofloxacin was the most commonly prescribed fluoroquinolone accounting for 70%. Patients who were taking gastric acid suppressing 1 week prior to admission accounted for 59% of patient admitted.

Conclusion: As the C. difficile severity score increased, the amount of patients taking antibiotics prior to admission lowered. Also, the likelihood of patients taking acid reducers prior to admission increased as severity scored increased. In addition, those who had higher severity scores were given more antibiotic combinations in the inpatient setting. In conclusion, fluoroquinolones were associated with more cases of C. difficile infections. Alternative antimicrobial therapy other than fluoroquinolones may reduce the incidence of C. difficile infections, as well as also reduce the acceleration of antibiotic resistance such as fluoroquinolone resistant pathogens.

Poster Title: Topical Atorvastatin to Reduce the Size and Severity of Stage I and II Pressure Ulcers in ICU Patients

Primary Author: Joshua Zecca, Palm Beach Atlantic University Gregory School of Pharmacy, Florida; **Email:** zeccaj@pba.edu

Additional Author (s):
Jocelyn Freimuth

Purpose: In acute care settings, reducing the length of stay and safely discharging or mobilizing the patient will continue to be a primary focus for health-systems management and patient-care teams alike. The innovative use of topical atorvastatin for the treatment of pressure ulcers in the ICU might help reduce the size of the ulcer and increase patient recovery. Pressure to an area of the skin for long or short periods of time can cause ischemia, which leads to damage of the tissue. In general, an estimated 2.5 million patients/yr are affected by pressure ulcers in just the United States.

Methods: Pharmacy researchers in a medical surgical teaching hospital in Tehran, Iran conducted a relatively novel study with compounded topically applied atorvastatin 1% ointment vs placebo, both in addition to standard care, in patients who were admitted to the ICU with a diagnosed stage I or II pressure ulcer. The study took place over 14 days had 104 patients in the final results, which were measured using the 2-Digit Stirling Pressure Score Severity Scale and measurement of surface area.

Results: Topical application of atorvastatin accelerated the healing of stage I and II pressure ulcers with statistical significance, compared to placebo. The change in pressure ulcer score and surface area showed statistically significant results in the study group compared to the control group.

Conclusion: Based on the results in this trial topical atorvastatin 1% ointment was beneficial in healing pressure ulcers and should be allowed for further exploration by practicing physicians in small cases to gather more evidence. More studies need to be done to solidify conclusiveness

and to increase its possible scope of application as an adjunct to stage III or IV pressure ulcers as well where applicable.

Poster Title: Evaluation of a procalcitonin guided algorithm on antibiotic utilization for lower respiratory tract infection in adults

Primary Author: Mary Skruck, Palm Beach Atlantic University Lloyd L Gregory School of Pharmacy, Florida; **Email:** skrucml@pba.edu

Additional Author (s):
Peter Duggan
Susan Tuttle
Harrison Bachmeier

Purpose: Procalcitonin (PCT) is a biomarker of bacterial infection, which rises and falls with the onset and resolution of infection, respectively. There have been multiple studies validating its use in the treatment of lower respiratory tract infections (LRTI), to guide antibiotic therapy and limit unnecessary use.

Methods: The institutional review board approved this retrospective chart review of patients admitted to a 356-bed community hospital between May and June 2016 with a suspected LRTI. Inclusion criteria included having at least one PCT serum level collected, age greater than or equal to 18 years, and a LRTI diagnosis upon admission. Exclusion criteria included patients with a primary diagnosis other than a LRTI, on antimicrobial therapy for a suspected non-respiratory infection, or immunocompromised. This analysis seeks to evaluate the use of a PCT-guided algorithm and subsequent antibiotic utilization in adult patients with suspected LRTI. Patient clinical stability was considered in the assessment of PCT results to direct antibiotic initiation or discontinuation as well. The primary outcome was the rate of PCT treatment algorithm recommendation acceptance. Secondary outcomes included the average hospital length of stay, average antibiotic treatment duration, and avoidance of antibiotic initiation.

Results: 124 patients were included in which 225 PCT serum concentrations were collected. 54.2 percent of the time the algorithm was followed, while 45.8 percent of the time it was not. Average antibiotic treatment days guided by the PCT algorithm included: chronic obstructive pulmonary disease (COPD) 1.8 , bronchitis 3.8, community acquired pneumonia (CAP) 5, hospital acquired pneumonia (HCAP) 9, unspecified pneumonia 6.8. Average antibiotic

treatment days not guided by the PCT algorithm included: COPD 6.2, bronchitis 4.8, CAP 7.75, HCAP 9.25, and unspecified pneumonia 5. The average length of stay was 7.4 days, and the percentage of avoidance of antibiotic initiation was 11.3.

Conclusion: In the setting of a suspected LRTI, antibiotic initiation, continuation, or discontinuation was determined by the PCT guided algorithm 54.2 percent of the time. Antibiotic usage was decreased as a result of testing PCT in LRTIs. Further studies would be beneficial to determine additional benefit in each type of LRTI.

Poster Title: Sofosbuvir and velpatasvir for the treatment of hepatitis C in genotypes 1-6: A comprehensive review

Primary Author: Andrea Blandon, Palm Beach Atlantic University Lloyd L. Gregory School of Pharmacy, Florida; **Email:** andrea_blandon@pba.edu

Additional Author (s):
David Dakwa
Donald Williams
Luis Galvan

Purpose: Hepatitis C is a viral infection of the liver that if left untreated can lead to inflammation, chronic hepatitis and other serious complications such as cirrhosis. This virus has six major genotypes that play a role in the prognosis of the disease as well as its treatment options. Despite current management for the specific genotypes, sofosbuvir-velpatasvir is the first available pangenotypic NS5A-NS5B inhibitor to treat all six genotypes. The purpose of this review is to evaluate the safety and efficacy of this single pill combination regimen with or without ribavirin for the six major genotypes of the hepatitis C virus.

Methods: Each trial was approved by the institutional review board or independent ethics committee at each participating study site. An open-label, phase II trial was conducted to evaluate three cohorts of eligible patients with or without compensated cirrhosis. Patients were randomized into 4 groups in a 1:1:1:1 ratio and received a 12 week regimen of a single oral daily dose of sofosbuvir 400 mg plus velpatasvir 25 mg, velpatasvir 25 mg with ribavirin, velpatasvir 100 mg, or velpatasvir 100 mg with ribavirin. A phase III (ASTRAL-1), double-blinded, placebo controlled trial was conducted to evaluate a combination fixed dose of sofosbuvir-velpatasvir versus placebo in hepatitis C genotypes 1, 2 and 4-6 over 12 weeks in patients with or without compensated cirrhosis. ASTRAL-2 and ASTRAL-3 are phase III randomized trials that were conducted to evaluate a fixed once daily oral dose of sofosbuvir-velpatasvir combination versus sofosbuvir plus weight based ribavirin for 12 weeks in hepatitis C genotype 2 and 24 weeks in genotype 3 in a 1:1 ratio. The primary end point for all trials was sustained virologic response at 12 weeks after the end of therapy. It was determined that 120 patients in ASTRAL-2 and 250 patients in ASTRAL-3 were needed to provide greater than 90 percent power to establish

noninferiority on the basis of sustained virologic response of 94 percent and 89 percent, respectively.

Results: In cohort one of the phase II trial, two groups reached 100 percent sustained virologic response while the other two groups reached an 85 percent and 96 percent, respectively. For cohort two, sustained virologic response rates were 58, 84, 88 and 96 percent. In cohort three, two groups reached 100 percent while the other two groups reached 97 percent and 96 percent, respectively. The ASTRAL-1 trial evaluating genotypes 1-2 and 4-6 was found to have a sustained virologic response of 99 percent in patients receiving sofosbuvir-velpatasvir (95 percent confidence interval, 98 to greater than 99) while patients who received placebo obtained no sustained virologic response. In the ASTRAL-2 trial evaluating genotype 2 infections, patients had sustained virologic response in the sofosbuvir–velpatasvir group at 99 percent (95 percent confidence interval, 96-100) compared to the 94 percent rate (95 percent confidence interval, 88 to 97) in the sofosbuvir–ribavirin group (P-value equals 0.02). In the ASTRAL 3 trial evaluating genotype 3 infections, patients had sustained virologic response in the sofosbuvir–velpatasvir group at 95 percent (95 percent confidence interval, 92-98) compared to the 80 percent rate (95 percent confidence interval, 75-85) in the sofosbuvir–ribavirin group (P-value less than 0.001).

Conclusion: Sofosbuvir-velpatasvir given as a once daily fixed dose combination for 12 weeks is a safe, well-tolerated and effective option for the treatment of hepatitis C infection in genotypes 1-6 in patients with or without compensated cirrhosis. All phase III trials demonstrated sustained virologic response rates at 12 weeks of therapy ranging from 94-100 percent with sofosbuvir-velpatasvir. Other studies also confirm its safety and efficacy in HIV co-infected patients as well as in decompensated liver disease.

Poster Title: Rolapitant for the prevention of delayed nausea and vomiting from emetogenic cancer chemotherapy

Primary Author: David Dakwa, Palm Beach Atlantic University Lloyd L. Gregory School of Pharmacy, Florida; **Email:** david_dakwa@pba.edu

Additional Author (s):
Natalie Mella
Lisa Mella
Beshoi Wahba

Purpose: Chemotherapy-induced nausea and vomiting is one of the most distressful side effects of anti-neoplastic agents and continues to have a negative impact on the quality of life in cancer patients receiving treatment. Seventy to eighty percent of cancer patients experience a form of chemotherapy-induced nausea and vomiting whether it is acute, delayed, anticipatory, breakthrough, or refractory. Despite current management, rolapitant has been developed to prevent delayed phase emesis. The purpose of this review is to evaluate the safety and efficacy of rolapitant for prevention of chemotherapy-induced nausea and vomiting in cancer patients receiving moderately or highly emetogenic chemotherapy.

Methods: The institutional review boards at every study site approved the protocol for each trial. Global, randomized, double-blind, active-controlled phase III studies were conducted with adult cancer patients who had not received moderately or highly emetogenic chemotherapy before. Patients were randomized in a 1:1 ratio in all trials to either one oral dose of rolapitant 180 milligrams or matching placebo 1 to 2 hours before chemotherapy administration on day 1. All patients received granisetron 2 milligrams plus dexamethasone 20 milligrams 30 minutes before chemotherapy and granisetron 2 milligrams was administered to all patients once daily on days 2 and 3. The primary efficacy endpoint for all trials was the proportion of patients achieving a complete response defined as no emesis or use of rescue medication greater than 24 to 120 hours chemotherapy initiation. It was estimated that 650 patients in each treatment group for moderately emetogenic chemotherapy would provide 90 percent power to detect an absolute difference of 9 percent in complete responses in the delayed phase between rolapitant and active control. It was determined that 257 patients in each treatment group for

highly emetogenic chemotherapy would provide 93 percent power to detect an absolute difference of 15 percent in complete responses in the delayed phase between rolapitant and active control. Each trial used Kaplan-Meier methodology to summarize time-to-first emesis or use of rescue medication.

Results: In regards to the moderately emetogenic chemotherapy regimen, a significantly greater proportion of patients assigned treatment with rolapitant had a complete response in the delayed phase than did those randomized to active control (475 [71 percent] vs 410 [62 percent], odds ratio 1.6, 95 percent confidence interval 1.2 to 2.0; p-value equals 0.0002). With highly emetogenic chemotherapy regimen in the HEC-1, HEC-2 and pooled studies, treatment with rolapitant also resulted in a significantly greater proportion of patients having a complete response in the delayed phase compared with active control (HEC-1: 192 [73 percent] versus 153 [58 percent]; odds ratio 1.9, 95 percent confidence interval 1.3 to 2.7; p-value is equal to 0.0006; HEC-2: 190 [70 percent] versus 169 [62 percent]; odds ratio 1.4, 95 percent confidence interval 1.0 to 2.1; p-value is equal to 0.0426; pooled studies: 382 [71 percent] versus 322 [60 percent], odds ratio 1.6, 95 percent confidence interval 1.3 to 2.1; p-value is equal to 0.0001). Rolapitant was well tolerated, with similar frequencies of treatment-emergent adverse events to those reported in the active control group such as constipation, fatigue, dizziness, and headache.

Conclusion: Both studies utilizing moderately emetogenic and highly emetogenic chemotherapy demonstrated statistically significant superiority of rolapitant over active control. A single oral dose of rolapitant 180 milligrams 1 to 2 hours before chemotherapy administration in combination with oral or intravenous serotonin receptor antagonists and dexamethasone is a safe and effective treatment for the prevention of delayed nausea and vomiting associated with initial and repeat courses of emetogenic cancer chemotherapy.

Poster Title: Empiric treatment of anti N-methyl-D-aspartate (NMDA) receptor encephalitis with intravenous immunoglobulin (IVIG) and corticosteroids

Primary Author: Rishita Patel, University of Florida, Florida; **Email:** rpatel38@ufl.edu

Purpose: This case study illustrates the empiric use of IVIG and corticosteroids for anti-NMDA receptor encephalitis. A 35 year old white female presented to the emergency department (ED) complaining of difficulty collecting her thoughts. She denied any personal or family psychiatric history. Patient had visited the ED three times within the previous week; once for fever, nausea, vomiting, and subsequently for insomnia and anxiety. She was treated adequately and discharged home. However, this time she was admitted to the psychiatry unit for further evaluation. Initial labs and computed tomography (CT) were unremarkable. However the urine drug screen was positive for cannabis. Patient initially denied using any substances, but later admitted to rarely using marijuana. The mental status exam performed by the psychiatrist indicated the patient had mixed hallucinations, delusions, and disorganized speech. She was diagnosed with acute psychosis; with a differential diagnosis of general medical condition, schizophrenia, and substance induced psychosis and was started on risperidone. Her psychosis, insomnia, and agitation worsened over the next week despite treatment, often requiring restraints and emergency doses of haloperidol, lorazepam and diphenhydramine. Olanzapine and valproic acid were added to her treatment. Ten days after admission, the psychiatrist noted symptoms of catatonia; including palilalia, verbigeration, mannerisms, and stimulus bound behavior. Lorazepam was initiated to break the catatonia and haloperidol was discontinued. However, there was no improvement in her psychotic symptoms. Neurology evaluation indicated no signs of cerebrospinal fluid (CSF) infection or encephalitis (no fever, decreased level of consciousness and/or seizures). Neurology ordered tests to rule out CNS vasculitis, seizure activity, systemic lupus erythematosus or paraneoplastic syndrome causing inflammation, Wilson disease, human immunodeficiency virus (HIV), or CNS lymphoma. A lumbar puncture (LP) was ordered to evaluate for herpes simplex virus (HSV) and blood samples were obtained for NMDA antibodies, glucose, protein, cell count, differential, and gram stain with culture. A LP was not obtained as the patient was extremely agitated. All other tests were negative/normal except for positive NMDA antibodies in the serum. It was suspected that the patient had NMDA receptor encephalitis, however a clear diagnosis could not be confirmed until CSF was evaluated. Twenty days after admission, the patient was transferred to a medical

floor and a LP was performed 5 days later. One week after the LP, the NMDA CSF sample was found to be insufficient. To prevent further delay in treatment, a second LP was performed and the patient was empirically treated with 0.4 g/kg IVIG every 24 hours for 6 days and methylprednisolone 500 mg IV three times a day for three days with tapering dose over next week. She started showing improvement within 24 hours of initiating empiric treatment. She slept better, was less agitated, did not require restraints and was able to hold a reasonable conversation. One week after initiation of empiric therapy, the LP results revealed NMDA semiquantitative 80 times upper normal limit, confirming the diagnosis of anti-NMDA receptor encephalitis. Another LP was performed the next day to evaluate the effect of treatment. Seven days later, NMDA semiquantitative was 20 times upper normal limit, indicating effectiveness of the empiric therapy. The patient was discharged home 18 days after initiating empiric treatment. This case study demonstrates a patient with atypical presentation of anti-NMDA receptor encephalitis, including normal EEG and MRI. The patient's agitation and subsequent delay in obtaining a sufficient LP further delayed firm diagnosis. This study proposes the option of empiric treatment with IVIG and corticosteroids in patients having severe symptoms of anti-NMDA encephalitis, a positive serum sample for NMDA antibodies with all other medical reasons ruled out, however, firm diagnosis is delayed due to lack of LP.

Poster Title: Nitroprusside: controlling blood pressure without bottoming out the budget

Primary Author: Mika Heister, University of Florida, Florida; **Email:** mikaheister1@ufl.edu

Additional Author (s):
Brian Brown
Amanda Mixson

Purpose: Lack of competition on the generic drug market has led to substantial price increases for a handful of generic drugs including sodium nitroprusside. The cost of one 50mg/2mL vial has increased from $6 per vial in 2012 to the current price of $830. Sodium nitroprusside, a potent intravenous vasodilator and venodilator, is routinely used in the cardiac operating room and cardiac intensive care unit. Last year, Johns Hopkins All Children's Hospital spent a calculated $633,290 on this medication. The use of nitroprusside was reviewed over one year to catalog current use, establish criteria for restrictions, and determine potential cost-effective alternatives.

Methods: A medication use evaluation identified 171 patients who received sodium nitroprusside from August 1, 2015 through July 31, 2016. The data collected included: patient demographics, indication, total number of orders (including orders from anesthesia), location of the patient at the time nitroprusside was ordered, and whether the dose was administered or wasted. The patients were then categorized into five age groups for further analysis. The age groups were as follows: neonate (< 28 days), infant (28 days – 1 year), toddler (1-3 years), child (3-12 years), and adult (≥ 12 years). A cost savings analysis was performed by comparing the cost of treatment with nitroprusside to the cost of treatment if an equivalent dose of nicardipine had been used.

Results: A total of 462 drip orders for nitroprusside were entered and prepared by pharmacy over the one year time period. An additional 184 drips were prepared by anesthesia. Of the total orders dispensed from the pharmacy, only 322 (69 percent) were administered to the patient and of the total orders entered by anesthesia, only 133 were administered to the patient (72 percent). The calculated waste came to a total of 218 vials of nitroprusside equating to $180,940. Furthermore, if a nicardipine drip had been ordered instead of a nitroprusside drip

in all age groups excluding neonates, the hospital would have saved an estimated $546,865. If the same number of vials were wasted over the year, the waste would equated to $3,270.

Conclusion: The results of this medication use evaluation demonstrate a need for the development of criteria for restrictions due to the large amount of waste. The goal of developing restrictions is to promote cost savings through decreased medication use by recommending lower cost alternatives such as nicardipine.

Poster Title: Repackaging otic ciprofloxacin and dexamethasone for use during myringotomy with tympanostomy tubes procedures in pediatric patients results in cost savings

Primary Author: Zuzana Blackwood, University of Florida College of Pharmacy, Florida; **Email:** zblackwood@ufl.edu

Additional Author (s):
Katie Namtu

Purpose: Ciprofloxacin and dexamethasone is an otic suspension that is used intraoperatively and post-operatively in patients with acute otitis media with otorrhea who undergo myringotomy with tympanostomy, as well as in patients with acute otitis externa. Given the high frequency of its utilization during ear nose and throat (ENT) procedures and the high cost burden, literature to support its use was evaluated, and a medication use evaluation was conducted.

Methods: A retrospective analysis of a sample of 49 patients who received ciprofloxacin and dexamethasone from January 1, 2016 through March 30, 2016 was performed to determine the most common dose, frequency, and the length of therapy. The data collected included the initiating service, the indication, the number of drops and doses administered to each patient, patient specific frequency of administration, the number of bottles purchased, and the cost per a bottle of ciprofloxacin and dexamethasone. The data was then analyzed to determine the number of doses dispensed, the total volume dispensed, the total volume administered, and the percent of the drug wasted. Further, the wastage percentage determined from the sample analysis was applied to the actual annual data to estimate annual wastage volume. Data was also collected on the number of bottles dispensed to the entire patient population between March 1, 2015 and February 29, 2016.

Results: Based on the findings of this MUE about 89 percent of ciprofloxacin and dexamethasone is utilized intraoperatively or postoperatively in patients with acute otitis media with otorrhea undergoing myringotomy with tympanostomy tubes. The conducted literature review supports the use of ciprofloxacin and dexamethasone for the above indication

in pediatric patients age 6 months or older. Further, it was found that the most commonly administered dose during or shortly after the procedure was 4 drops in each affected ear twice a day. The findings show that only about 6 percent of the 7.5 milliliter bottle was administered to inpatients, and the rest of it was wasted. Based on the above, a proposal was developed for alternative packaging of ciprofloxacin and dexamethasone that would result in yearly savings of 43,626 dollars.

Conclusion: This evaluation identified circumstances and procedures that resulted in ciprofloxacin and dexamethasone wastage, and led to an evaluation of an alternative protocol that would decrease drug wastage and result in cost savings. The department of pharmacy at Johns Hopkins All Children's Hospital is currently in the planning phase of a repackaging program to realize these savings.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Evaluative Study

Session-Board Number: 2-088

Poster Title: Retrospective review of aztreonam utilization and cost-analysis at a multi-center health system

Primary Author: Jillian Sullivan, University of Florida College of Pharmacy, Florida; **Email:** jillianksullivan@ufl.edu

Additional Author (s):
Merieme Drhouri-Bengara
Kimberly Hunger
Joseph Bratsch

Purpose: Aztreonam is a monobactam antibiotic that offers coverage of gram-negative bacteria, including Pseudomonas spp. It is commonly used for penicillin allergic patients due to its lack of cross-reactivity with penicillins. However, due to its high cost and narrow antibiotic coverage, use is intended to be limited. The primary endpoint of this study was to determine the appropriateness of aztreonam utilization at a multi-center health system; consisting of one level II trauma center and three community hospitals. Additionally, the secondary outcome was to assess potential cost-savings if alternative agents were substituted when the utilization of aztreonam was deemed inappropriate.

Methods: A retrospective patient chart review was conducted for the months of January through March 2016 to determine the appropriateness of aztreonam utilization. Patient-reported medication allergy data was collected, as well as culture and susceptibility results for indications besides empiric treatment. Aztreonam use was deemed appropriate for patients with documented severe penicillin/beta-lactam allergies (including anaphylaxis, urticaria, and angioedema) if the indication was for: (1) empiric coverage of gram-negative organisms, or (2) documented culture with susceptible organisms. Use was deemed inappropriate if aztreonam was used (1) without documentation of a severe penicillin/beta-lactam allergy, (2) when aztreonam was administered in combination with another beta-lactam antibiotic, or (3) for the treatment of suspected gram-positive or anaerobic organisms. Once the initial data was collected, cost analysis of aztreonam use was evaluated. This was performed through evaluating the drug of choice given patient specific characteristics, such as indication for antibiotic use, concurrent antibiotics, culture and susceptibility report data (when available),

and renal function. The acquisition cost of these alternative agents was compared to that of aztreonam when aztreonam utilization was deemed inappropriate. The course of the decided treatment for the alternative agents was adapted to mirror that of the same aztreonam treatment course to determine the total cost for the use of each of these agents. The cost-savings was then analyzed by comparing the costs of aztreonam with the alternative antibiotic.

Results: The results indicate that from January through March 2016, approximately 60% of all aztreonam utilization was deemed inappropriate per the criteria used in this study. The most common reason for inappropriate aztreonam utilization was due to allergy documentation with reactions listed as "unknown" or "other," which accounted for approximately 42.3% of all inappropriate aztreonam use. Of the patients who received aztreonam inappropriately, about one-third had no documentation of a severe penicillin/beta-lactam allergy, and roughly one-quarter had a reported penicillin/beta-lactam allergic reaction documented as a "mild" (i.e., rash, nausea, vomiting, or diarrhea). The total aztreonam cost across this health system was approximately $23,000 with almost $14,000 spent on inappropriate aztreonam use. When evaluating the patients that received aztreonam inappropriately, a cost-saving alternative could have been utilized with an estimated expense of $1,400. Overall, this would have provided an estimated cost-savings of over $12,000 for the quarter.

Conclusion: Overall the use of aztreonam across this health system was largely deemed inappropriate, and resulted in significant costs. The study results show that there were opportunities for cost savings demonstrated by the use of alternative agents and proper allergy evaluation. Moving forward, strategies to reduce the inappropriate utilization and avoidable costs associated with aztreonam will be implemented and their impact will be evaluated on a larger scale.

Poster Title: Evaluation of the use of a hyperkalemia order set in a community health system

Primary Author: Kristen Schwartz, University of Florida College of Pharmacy, Florida; **Email:** knschwar@ufl.edu

Additional Author (s):
Andrew Spiegel
John Armitstead

Purpose: Order sets are a type of clinical decision support tool that encourage evidence-based medical care and work to minimize adverse events and medication errors to support improved patient health outcomes. The purpose of this medication use evaluation (MUE) is to assess the extent of utilization of a recently implemented order set for the treatment of hyperkalemia in a community health system. This information could help to guide revisions to existing order sets and/or the creation of additional order sets to better provide clinicians with tools that encourage the practice of evidence-based, patient-centered care.

Methods: The Pharmacy Research & Scholarly Subcommittee approved this MUE. Patients with a serum potassium level greater than or equal to 6 mmol/L during the time frame of 1/1/2015 to 3/31/2015 were identified and evaluated for inclusion in this MUE. Patients were excluded if they were less than 18 years old, treated for hyperkalemia in the emergency department without subsequent inpatient admission, or had serum potassium levels that were indicated as being from a hemolyzed sample or otherwise invalidated through repeat laboratory testing. A total of 303 patients met these criteria and were included in the evaluation. The individual patients' electronic health records were then reviewed retrospectively to see if their hyperkalemia was or was not treated using the hyperkalemia order set, and if it was utilized, whether a pharmacist was involved in the process. Additional information was collected concerning: which medications from the order set were used to treat the hyperkalemia, whether general labs and monitoring were conducted per the order set protocol, whether medications and/or exogenous sources of potassium that can cause hyperkalemia were discontinued on the patient's profile, and whether other treatments were used to manage hyperkalemia (e.g. sodium polystyrene sulfonate, hemodialysis). Descriptive statistics were used to analyze the results.

Results: The mean serum potassium level was 6.58 plus or minus 0.607 mmol/L. The order set was used in 41.5 percent of cases and not used in 58.5 percent of cases. When the order set was used, pharmacists were involved in the process 40 percent of the time, either clarifying the order with the prescriber or entering the order set into the electronic order management system following a verbal order. Medication options from the order set and their usage were as follows: albuterol used in 26.1 percent of cases, calcium gluconate or calcium chloride used in 37.6 percent of cases, furosemide used in 13.9 percent of cases, insulin used in 50.5 percent of cases, and sodium bicarbonate used in 31.7 percent of cases. Two or more of these medications were used in combination to treat hyperkalemia 71.6 percent of the time. Non-order set options such as hemodialysis and/or sodium polystyrene sulfonate were used as part of the hyperkalemia management strategy 57.4 percent of the time. Hyperkalemia-causing medications and potassium supplements were discontinued from the patient's profile in 96.4 percent of cases. Laboratory monitoring was conducted in accordance with the order set's recommended frequency parameters in 28.4 percent of cases.

Conclusion: The hyperkalemia order set was used in over 41 percent of cases during the three-month study period following its implementation. Pharmacists were involved in the order set process in some way 40 percent of the time. Laboratory tests (e.g. BMP) and monitoring (e.g. finger stick blood glucose measurements) were usually completed more or less frequently than the general parameters from the order set. These results indicate that use of the order set was fairly common, though they highlight the opportunity to increase utilization. Pharmacists may continue to play an important role in the use of this hyperkalemia order set.

Submission Category: Cardiology/ Anticoagulation

Submission Type: Evaluative Study

Session-Board Number: 2-090

Poster Title: Bleeding complications due to direct oral anticoagulants at a large academic affiliated care center

Primary Author: Solomiya Virstyuk, University of Florida College of Pharmacy, Florida; **Email:** solomiyav@ufl.edu

Additional Author (s):
Marta A. Miyares

Purpose: Direct oral anticoagulants (DOACs) are common alternative anticoagulant agents to warfarin. These agents do not require routine monitoring and if prescribed properly have the potential to cause less major bleeding events versus warfarin. Jackson Memorial Hospital (JMH) has a pharmacist led prospective review system in place for approval of DOACs to assure appropriate prescribing and minimize adverse events. The purpose of this study was to investigate the rate at which inpatients prescribed either apixaban, rivaroxaban or dabigatran experienced a bleeding event compared to clinical trials.

Methods: This was a retrospective chart review of all admitted patients 18 years of age or older with an order for apixaban, rivaroxaban, or dabigatran. Charts of those who received at least one dose of a DOAC between October 2015 and May 2016 were screened for bleeding events using the 10th revision of the International Statistical Classification of Diseases and Related Health Problems codes. Bleeding events were classified as minor or major. Major bleeding events included fatal bleeding, and or intracranial, intraspinal, intraocular, retroperitoneal, intraarticular or pericardial, or intramuscular with compartment syndrome and or bleeding causing a fall in hemoglobin level of 2 grams per deciliter more, or leading to transfusion of two or more units of whole blood or red cells. Minor bleedings events were defined as any other bleeding such as hematuria, epistaxis and melena. Further investigation as attempted to determine if the DOAC was a probable cause of the bleeding event. Bleeding events were classified as occurring on admission or during the inpatient stay and stratified based on the DOAC used and indication it was used for. The primary outcome was the percentage of patient's who experienced a major or non-major bleeding event. Fisher's exact test was used to compare bleeding frequency at JMH to the bleeding frequency in each respective clinical trial. All institutional review board procedures were followed.

Results: Of the patients prescribed a DOAC 403 were included; 306 of these patients were prescribed apixaban, 82 rivaroxaban and 15 dabigatran. Overall bleeding rates were 3.6 percent in the apixaban group, 3.7 percent in the rivaroxaban group and none in the dabigatran group. In the apixaban group 11 patients experienced a bleed. Five of the patients that bled had an indication of venous thromboembolism (VTE); 3 major bleeds and 2 minor bleeds. The remaining six patients had an indication of atrial fibrillation. The bleeding rate was comparable to that in each respective clinical trial and the difference was not statistically significant. Of the rivaroxaban group 3 patients experienced a minor bleeding event and all had a VTE indication for the use of the DOAC. The difference between the JMH specific bleeding event rate identified in the rivaroxaban atrial fibrillation group was significantly lower from what was reported in the corresponding clinical trial. The statistical significance of this result is limited by small sample size of the cohort.

Conclusion: Results of this retrospective review indicate that with a pharmacist led prospective approval process the frequency of bleeding events can be kept similar if not lower to that of clinical trials. However, further studies are needed to confirm these findings.

Submission Category: Oncology

Submission Type: Case Report

Session-Board Number: 2-091

Poster Title: Dual sequential therapy with intraventricular cytarabine and rituximab in secondary CNS lymphoma

Primary Author: Jade Hefler, University of Florida College of Pharmacy, Florida; **Email:** jadehefler@ufl.edu

Additional Author (s):
Rebecca Nelson
Amy Browning
Rushang Patel

Purpose: This case report illustrates the potential role of sequential intraventricular rituximab and cytarabine administration for the treatment of refractory CNS lymphoma. A 52-year-old female with refractory diffuse large B-Cell Lymphoma developed recurrent CNS lymphoma following treatment with R-CHOP (6 cycles), high-dose methotrexate (2 doses), and radiation to the brain and mediastinum. She presented to the emergency department with altered mental status following an acute seizure. Computerized tomography (CT) of the brain demonstrated hypoattenuation concerning for advancement of tumor infiltration and edema. Subsequent brain magnetic resonance imaging (MRI) confirmed progression of lymphoma within the right aspect of the brainstem with vasogenic edema and a small subarachnoid hemorrhage. Brain imaging results were consistent with extensive lymphoma recurrence, warranting treatment with intraventricular chemotherapy.

Intraventricular rituximab may demonstrate clinical benefit in the setting of relapsed or refractory CNS lymphoma. Rubenstein et al. conducted a phase 1 dose-escalation study of intraventricular rituximab in patients with recurrent CNS Non-Hodgkin's Lymphoma. Complete response and cytologic response were demonstrated in over 40 percent of patients. A subsequent phase 1 multicenter study evaluated the safety and efficacy of intraventricular rituximab in combination with methotrexate for relapsed or refractory CNS lymphoma. Patients receiving 25 mg of intraventricular rituximab twice weekly for 4 weeks achieved 75 percent complete cytologic response and 43 percent overall complete response. Over 150 doses of intraventricular rituximab were administered without serious toxicity.

Intrathecal methotrexate was not chosen for treatment of this patient due to concern for methotrexate pneumonitis. The patient was given one dose of liposomal cytarabine and then

started on a modified CALGB (Cancer and Leukemia Group B) regimen consisting of intravenous rituximab and temozolamide. Based on the results from the Rubenstein et al. studies, biweekly intraventricular rituximab was started sequentially with intraventricular cytarabine. Throughout ten weeks of therapy, the patient remained confused, unable to follow commands, and combative with little to no change in condition. Analyses of cerebral spinal fluids were negative for malignancy and infection throughout the duration of therapy. After completion of two cycles of intraventricular rituximab and cytarabine, CT findings showed improvement in areas of pathologic enhancement including the supratentorial white matter, brainstem and left cerebellum with persistent hypoattenuation and vasogenic edema. MRI findings showed a decrease in size from 13 mm to 7 x 5.5 x 5 mm of the right brainstem mass lesion and improvement in surrounding edema. This response was maintained for approximately ten weeks at which point there was progression, and the patient was offered hospice care.

Submission Type: Evaluative Study

Session-Board Number: 2-092

Poster Title: Evaluating pain medication use patterns in patients undergoing total joint replacement surgery following a preoperative pain education seminar compared to the standard-of-care

Primary Author: James Alcorn, University of Florida College of Pharmacy, Florida; **Email:** jsalcorn@ufl.edu

Additional Author (s):
Carmen Trindade-Sueldo
Jim Goodwin

Purpose: Postoperative pain following orthopedic surgery is consistently cited as prevalent and problematic. Furthermore, pain after joint replacement is frequently undertreated. These facts lead to significant patient fear regarding postoperative pain. Our institution and staff orthopedic surgeon utilize a guideline-recommended multimodal approach to pain management following total joint replacement procedures. Additionally, we offer a similarly recommended preoperative education session that establishes appropriate pain management expectations, stresses the importance of rehabilitative therapy, and describes the multimodal approach employed at our institution. Existing literature has established the utility of these sessions in reducing lengths-of-stay and composite pain scores.

Methods: A retrospective chart review was conducted to identify patients who underwent total joint arthroplasty of their knee, shoulder, or hip between June 1, 2016 and August 31, 2016 at our suburban, 72 bed acute care hospital. Patients were then separated into groups based on their participation in a voluntary pre-surgical education session. Medication administration records were reviewed to identify the number of doses of targeted pain management medications administered during a patient's stay. These agents included acetaminophen, celecoxib, cyclobenzaprine, diazepam, fentanyl, gabapentin, hydrocodone-acetaminophen, ketorolac, hydromorphone, meperidine, morphine, oxycodone, oxycodone-acetaminophen, pregabalin, tapentadol, and tramadol. Patient length-of-stay was also compared between groups. Due to its design, this study is exempt from institutional review board approval.

Results: The mean number of doses administered to patients who attended the educational session was 13.5 ± 6.24 compared to 12.75 ± 5.33 (P=0.35) among those who did not attend such a session. The mean length-of-stay in the experimental group was 2.33 ± 0.675 and 2.36 ± 0.574 (P=0.453) in the control group.

Conclusion: Attendance of a voluntary pre-surgical educational session did not impact the number of doses of pain management medications a patient utilized while admitted. Further, there was no statistically significant difference in lengths-of-stay between groups. Limitations within this design include poor participation in pre-surgical education and a small sample size.

Poster Title: Serving the underserved population: A review of a community hospital prescription voucher program

Primary Author: Tyler Haney, University of Florida College of Pharmacy, Florida; **Email:** tylerdhaney@ufl.edu

Additional Author (s):
Kathleen Truelove

Purpose: A voucher program from Sarasota Memorial Hospital, a nonprofit hospital, offers free prescriptions for uninsured patients identified through case management. The voucher provides up to a 30-day supply. The hospital began participating in the 340B drug discount program in January 2015. In May 2016, it began participating in the contract pharmacy component of the program. This project was designed identify the disease states and the costs associated with those prescriptions by comparing the previously contracted price to 340B price. In addition, readmission rates of patients that received vouchers were assessed.

Methods: Prescriptions dispensed via the voucher program for patients 18 and older from January 1, 2016 to March 31, 2016 were reviewed after Institutional Review Board approval. Using retrospective chart review based upon the patients' hospital admission, the associated disease states and whether they were acute or chronic were identified. Patients were excluded if there was no disease state associated with the prescription. Readmission rates for these patients were reassessed after 30 days and 60 days. The previously contracted price of the prescriptions was compared to the 340B price during quarter three of 2016 and the prescription costs was ranked based on 340B price. The primary objective was to identify the disease states that present in our underinsured population and the costs associated with those disease states.

Results: Over three months, 204 patients received 529 prescriptions. Five disease states with the highest 340B prescription cost were identified: diabetes, asthma, heart failure, pneumonia, and deep vein thrombosis. There was a significant difference between the price of the previously contracted price and 340B price (p value less than 0.0001). There was no difference between readmission rates of acute and chronic conditions in either 30 day or 60 day

readmission rates (p values equal 0.45 and 0.46 respectively). The most common disease states to be readmitted were asthma and diabetes for 30 days, and asthma and COPD for 60 days. Only 57.2% of prescriptions associated with chronic disease states were written for a 30 days supply.

Conclusion: In the uninsured population that received prescription vouchers, diabetes, asthma, and COPD were the most frequently presenting conditions. Thirty and sixty day readmission occurred most often with asthma, diabetes, and COPD. These also represented the highest spending in the voucher program.

Submission Type: Descriptive Report

Session-Board Number: 2-094

Poster Title: Not so poor-phyria: Cost containment strategies for hemin

Primary Author: Megan Galarza, University of Florida College of Pharmacy, Florida; **Email:** mgalarza@ufl.edu

Additional Author (s):
Arielle Ruff

Purpose: Medication costs and utilization continue to rise, greatly impacting pharmacy health system budgets. Developing cost management initiatives are integral in maintaining the financial performance of the pharmacy department. Although drug expenditures are important considerations, patient outcomes and quality of care remain the top priority. Acute intermittent porphyria is a rare disorder that affects the production of heme and is treated with an orphan drug called hemin. The usual treatment course includes 4-5 doses of hemin, each dose costing institutions nearly $7,000. This project was designed to assess potential solutions for hospitals caring for patients requiring this high cost medication.

Methods: The institutional ethics committee approved this retrospective medication review. Inclusion criteria consisted of patients who received hemin administration over the course of approximately 2.5 years. Patient data collected included dose of hemin and number of doses received. The total number of doses over this time period had a significant impact on the pharmacy department's drug expenditures. Potential resources were researched and examined to offset this drug cost. The 340B program was identified as a drug discount program that offers hemin at a significantly lower cost than hospital pharmacy department purchase price. Additionally, the manufacturer of hemin (Recordati) offers a patient assistance program for uninsured patients who require hemin administration.

Results: During the 2.5 year time period analyzed, 155 doses were received by 4 patients. The approximate drug cost was $1,000,000. On average, most patients received 4-5 doses during their hospital admission. The cost of receiving the same course of treatment through the 340B drug discount program can be as low as approximately $25. The potential savings for an institution are robust, approximately $30,000 per treatment course for the drug alone.

Recordati provides hemin at no cost for uninsured patients who meet pre-specified requirements.

Conclusion: Hemin administration is a costly treatment that has a significant impact on a pharmacy department's expenditures. Although substantial savings can be obtained through the 340B drug discount program or manufacturer patient assistance programs, the process of obtaining these discounts can be intricate and labor intensive. The information and resources identified may be beneficial for any hospital also facing the repeated use of a high cost drug like hemin.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Evaluative Study

Session-Board Number: 2-095

Poster Title: Evaluation of intravenous unfractionated heparin use at a community health system

Primary Author: Arya Cader, University of Florida College of Pharmacy, Florida; **Email:** acader@ufl.edu

Additional Author (s):
Ryan Hire
Peter Duggan
Kristin Quarterman

Purpose: A lot goes behind the safe use of heparin; it requires weight-based dosing, frequent monitoring through activated partial thromboplastin times (aPTT), and rate adjustments depending on what the aPTT labs are. The aim of this evaluation is to examine the use of heparin within the health system in order to see if nuanced changes to protocol and best practice alerts (BPAs) have resulted in a reduction in heparin administration errors and an improvement in time to 2 consecutive therapeutic aPTT values.

Methods: The institutional review board approved a retrospective chart review that will evaluate the usage of intravenous heparin infusions in patients within the Lee Memorial Health System. Data will be collected from a maximum of 120 patients that were admitted to Cape Coral Hospital, Gulf Coast Medical Center, HealthPark Medical Center, and Lee Memorial Hospital that received IV heparin during the period of April to May 2016. Patients will be included if they were above the age of 18 years and received heparin for more than 24 hours. 15 patients on low dose heparin drips and 15 patients on standard dose heparin drips will be analyzed per hospital. Potential patients will be analyzed for inclusion via a report generated through EPIC ProDiver. The primary outcome for this MUE will be the elapsed time (in hours) to get 2 consecutive therapeutic aPTT levels. Statistics for each observational data measure collected will be descriptive in nature only.

Results: The last heparin use evaluation was conducted in 2013, as a health system the time to two consecutive therapeutic aPTTs was 38.4 hours. After all the data was collected for the

current heparin use evaluation the time to reach two therapeutic aPTTs was calculated to be 31.7 hours, which is a 6.7 hour reduction.

Conclusion: Best practice alerts and nuanced changes to the heparin protocol did reduce the overall time to two therapeutic aPTTs within the health system. However, there were several areas identified that seemed problematic with heparin administrations, these areas will need to be addressed and solutions will need to be discussed in future evaluations.

Poster Title: Establishing a comprehensive and efficient guideline for intravenous immune globulin preparation, dosage, and administration to be used by clinicians within a hospital setting.

Primary Author: Taylor Schenley, University of Florida College of Pharmacy, Florida; **Email:** tschenley@ufl.edu

Additional Author (s):
Mohammed Ibrahim

Purpose: Intravenous immune globulin is used to strengthen the body's natural defense system to decrease the risk of infection in persons with a weakened immune system. When given in the setting of hypogammaglobulinemia, antibody deficiency disorders, or other immunodeficiency states, intravenous immune globulin preparations act by providing antibodies against a broad range of pathogens. Currently, there are no specific guidelines published in the literature that outlines the appropriate administration and usage of immune globulin. This set of guidelines was created to provide clinicians with a quick and comprehensive reference on how to dose, prepare, and administer immune globulin.

Methods: A registered pharmacist with advanced clinical training in oncology devised an administration guideline and quick reference sheet for the appropriate preparation, dosage, and administration of intravenous immune globulin. The administration guideline includes appropriate evidence-based recommendations on rates of infusion, dose adjustments, and precautions with use. The quick reference sheet includes a list of popularly utilized immune globulin products and information outlining how the immune globulin product is supplied, infused, administered, dosed, and any additional notes regarding special populations and precautions to be taken. Additionally, a pharmacy student working with this pharmacist created an evaluation document to objectively determine the comprehensiveness and accuracy of these resources. This evaluation document was divided into multiple categories such as comprehensiveness, organization, and efficiency of use. Each category was graded with a corresponding numeric scale that represented the strengths or weakness of the resources. Clinicians were asked to appropriately identify patients that qualified for immune globulin therapy and properly categorize these patients according to patient specific factors (age,

immune status, pregnancy). The clinicians were then encouraged to use this guideline and reference sheet as their primary tool for decision making. Retrospectively, those who participated in using the guideline were given the evaluation form and asked to evaluate the overall comprehensiveness of these resources in aiding their ability to make clinical decisions regarding intravenous immune globulin usage.

Results: Two pharmacists successfully were evaluated after using the guidelines and reference sheets. Both pharmacists returned their evaluations and classified the documents as being comprehensive, organized, evidence-based, and efficient. All of the categories on the evaluation sheet received scores of five out of a possible five points. The clinicians using the document verbalized that they felt more comfortable using the comprehensive guidelines and planned to continue using the resources to make clinical decisions moving forward.

Conclusion: Comprehensive and efficient guidelines for intravenous immune globulin preparation, dosage, and administration proved to be a helpful tool in assisting specialized clinicians with their decisions making and may be a useful tool that can be expanded and utilized in additional practice settings within a hospital setting.

Poster Title: Pharmacy impact on 30-day readmission rates: Collaboration in a Heart Function Clinic

Primary Author: Kaitlyn Bice, University of Florida College of Pharmacy, Florida; **Email:** kmbice815@ufl.edu

Purpose: Heart failure is a serious epidemic, affecting as many as 5.8 million people in the US and 23 million people worldwide. High readmission rates, especially within the first thirty days, for patients with reduced ejection fraction (≤ 40%) calls for special interventions to help combat this problem. Patients with heart failure would benefit from having an interdisciplinary team that specializes on all aspects of the disease. Pharmacist involvement in heart failure clinics aims to target medication management as well as lifestyle modifications.

Methods: A retrospective study conducted at a single institution, which targeted patients that were discharged from the hospital with a primary diagnosis of heart failure from between February 1, 2016 to May 31, 2016. Inclusion criteria included age ≥ 18 years of age, a primary diagnosis of heart failure, and receiving guideline appropriate therapy. Exclusion criteria include ejection fraction > 40%, ECHO results unavailable, patients not admitted to the hospital, and patients admitted for a planned procedure such as pacemaker placement. Data collection included patient information, any previous diagnosis of heart failure, comorbidities, ejection fraction, Heart Function Clinic follow up post discharge, and if patient was readmitted to the same hospital within 30 days.

Results: During the four-month study period, 257 patients were discharged from the hospital with a primary diagnosis of heart failure. 130 patients were excluded for the following reasons: EF > 40%, preplanned procedures, patients not admitted, and duplicate date entry. Of the 127 included in the analysis, 24 patients followed up in the Heart Function Clinic and 4 (16.7%) of these patients were readmitted within 30 days. Additionally, 25 patients (24.3%) were readmitted within 30 days that did not follow up with the Heart Function Clinic. This resulted in a 31.3% relative risk reduction (7.6% ARR) with regards to readmission rates within 30 days for patients with a clinic follow up compared to those without.

Conclusion: In heart failure patients with reduced ejection fraction, upon hospital discharge, follow up in an interdisciplinary Heart Function Clinic resulted in a lower readmission rate within 30 days compared to those who did not. Heart Function Clinics offer bridging between hospital discharge and follow up appointments with cardiologists. This is important because such appointments often do not occur within the first 30 days leading to higher readmissions. Pharmacy partnership in such clinics stands to have a positive impact. Between medication optimization and patient education, pharmacists can become a crucial member of the interdisciplinary team increasing patients' overall quality of life.

Poster Title: Potential risk of accidental and fatal 5-FU (Fluorouracil) toxicity in patients using infusion pumps

Primary Author: Victoria Mottola, University of Florida College of Pharmacy, Florida; **Email:** vmottola99@ufl.edu

Additional Author (s):
Mohammed Ibrahim
Judith Bowden

Purpose: This case illustrates a potentially deadly drug overdose in a patient receiving a 5-FU (Fluorouracil) infusion for chemotherapy. The patient was a 69 year old female with a diagnosis of cancer of the appendix with peritoneal metastases and a BSA of 1.65 meters squared. She was initiated on Modified FOLFOX6 chemotherapy for cancer treatment. Modified FOLFOX6 consists of oxaliplatin 85 milligrams per meter squared IV over 2 hours concurrent with folinic acid 400 milligrams per meter squared IV over 2 hours followed by 5-FU (Fluorouracil) 400 milligrams per meter squared IV bolus on day 1, then 1,200 milligrams per meter squared per day times 2 days (total 2,400 milligrams per meter squared over 46 to 48 hours) IV continuous infusion. The cycle is repeated every 2 weeks. On Day 1 of Cycle 12 on 5/23/16, this patient received 5-FU (Fluorouracil) 400 milligrams per meter squared which equaled 660 mg IV bolus over 5 minutes followed by 5-FU (Fluorouracil) 2,400 milligrams per meter squared which equaled 3,960 milligrams at 30 milliliters per hour over 4.6 hours instead of 3 milliliters per hour over 46 hours. The infusion rate per hour was programmed incorrectly by the nurse at 30 milliliters per hour instead of 3 milliliters per hour and the infusion pump did not have safety options to prevent this error from happening. The WalkMed 350 VL infusion pump must be clicked once to erase the old rate and to bring the rate back to zero. If it is quickly clicked twice then it moves the decimal point to the right. The nurse entered the infusion rate per hour and quickly clicked twice to zero the pump, ultimately moving the decimal point to the right by mistake, and therefore entering the rate at 10 times the intended rate (30 milliliters per hour instead of 3 milliliters per hour). The patient was given the pump with the incorrect infusion rate and sent home for the night. The patient made a call to the emergency hotline that night at 2235 when she noticed the infusion stopped and the bag was empty. She was advised to call her physician immediately. The patient arrived at clinic the morning after her pump stopped

stating "the chemo on my pump completed last night." The pump was assessed and chemotherapy infusion had completed. The patient had turned the pump off and clamped the mediport line. The patient denied concerns or complaints, and just stated that she felt more fatigued than usual. The oncologist assessed the patient at chair side, pharmacy was made aware, and the patient was admitted to the hospital for supportive care and lab observation. The patient was started on uridine triacetate that night (05/24/2016) at 2000. The dose ordered was 10 grams given orally every six hours for a total of 20 doses. The last dose was given on 05/29/16 at 1400 and the patient was discharged with no overt problems from 5-FU (Fluorouracil) toxicity. She followed-up with the oncologist on Tuesday, 05/31/16. The pump manufacturing company was contacted and informed about the safety concern and they assured that they are working to develop a new pump that will have improved safety features. 5-FU toxicity is usually fatal as shown in the literature by other case reports. As this case suggests, WalkMed 350 VL infusion pumps, which are used commonly in many hospitals for drug infusion, have faulty safety options which make it simple for a decimal error to occur. It is imperative to double check infusion rate entry while using these types of pumps to prevent adverse or fatal medication related errors.

Poster Title: Evaluation of tolerability and side effects of inhaled epoprostenol in patients with high pulmonary arterial pressures

Primary Author: Samantha Parsons, University of Florida College of Pharmacy, Florida; **Email:** slparsons@ufl.edu

Additional Author (s):
William Kernan
Lori Milicevic
Jinesh Mehta

Purpose: A preferred pharmacologic treatment for management of acute high pulmonary pressures after surgery includes the administration of inhaled nitric oxide (iNO) and inhaled epoprostenol (iEPO). iNO requires frequent monitoring, is associated with toxicity and is expensive compared to iEPO. Two formulations of iEPO are available, Flolan® (iFLO) and Veletri® (iVEL). Studies to date compare iNO to iFLO and show the inhaled prostacyclin is an alternative to iNO, but studies using iVEL are lacking. The purpose of this evaluation is to determine the tolerability and side effects of iVEL as an option for use in patients with high pulmonary pressures.

Methods: The institutional review board approved this single center, retrospective drug-utilization evaluation. The electronic medical record was used to report all patients who were administered iVEL over a total of thirteen months (June 1, 2015 through August 31, 2016). All patients who received the medication were included to determine the primary endpoint of adverse event rate. Adverse events were determined by evaluation of inpatient notes through the duration of medication administration including nursing, medical, physical therapy, surgical, respiratory, pharmacy and inpatient healthcare provider notes. Bronchospasm adverse events were determined by initiation of bronchodilator medication after iVEL initiation. Secondary endpoints were pulmonary arterial pressure, mean pulmonary arterial pressure, and cardiac index. Duration of therapy and length of hospital stay were also reported. The primary endpoint of adverse event rate, as well as patient sex and ethnicity, are reported as a percent. All other secondary endpoints and baseline characteristics are reported as a mean plus or minus standard deviation.

Results: Six patients over the time period received iVEL. Of the six patients, only one (16.67 percent) experienced an adverse event. The adverse event noted was nausea and vomiting and was non-life threatening. No patient experienced life-threatening adverse events from the administration of iVEL, and no patients experienced bronchospasms. The average duration of therapy was 79 hours (median equals 82 hours). The average baseline pulmonary arterial pressure (mPAP) prior to iVEL initiation was 40.0 mmHg plus or minus 11.53 mmHg, while the average mPAP throughout the duration of medication administration was 26.97 mmHg plus or minus 8.72 mmHg.

Conclusion: The tolerability of iVEL is favorable and the side effects observed in this study proved to be non-life threating and amendable. Only one patient had an adverse event, the medication was continued and the reaction was treated with appropriate nausea medication. This evaluation shows that this medication is well tolerated, however larger evaluations over a more diverse population would be beneficial.

Poster Title: Review of antimicrobial stewardship in a level III neonatal intensive care unit (NICU)

Primary Author: Paige Bishop, University of Florida College of Pharmacy, Florida; **Email:** paigeajohns@ufl.edu

Additional Author (s):
Stephanie Spikes
Bill Renfro

Purpose: The University of Florida Health (UF Health) neonatology service began an antibiotic monitoring team in 1988 aiming to decrease antibiotic use and resistance. The neonatology providers believe that antimicrobial use should be formally reexamined and consequently enrolled in the Vermont Oxford Network (VON) for their 2016 continuous quality improvement initiative "Using Antibiotics Wisely." The initiative's long-term goal is to increase knowledge among staff and parents on best antibiotic practices and decrease the use of antibiotics. The objective of this study is to determine the baseline characteristics of antibiotic use in the NICU at UF Health before the VON initiative.

Methods: We compiled a 3-month retrospective review from November 1, 2015 to January 31, 2016 to determine pre-VON initiative characteristics for use of antibiotics in the UF Health Jacksonville NICU. Patient charts were reviewed in the electronic health record, and data was recorded regarding gestational age, gender, antibiotic agents used, indications for antibiotic use, number of antibiotic courses, culture results, and laboratory values including white blood cells (WBC), band neutrophils, platelets, and C-reactive protein (CRP) at the time of antibiotic initiation. The mean gestational age, percentage of males and females, mean number of antibiotic courses per patient, mean duration of antibiotic course, mean WBC, mean percentage of band neutrophils, mean number of platelets, and CRP range, was determined. The percentage of antibiotic courses for each indication out of the total number of courses was also determined. The percentage of courses lasting greater than 48 hours and percentage of courses lasting greater than 48 hours with positive cultures for all indications and for sepsis rule out only were determined. Days of therapy (DOT) were also determined and the antibiotic

utilization rate (AUR) was calculated as DOT divided by census for the same time period multiplied by 100 to equal 100 patient days.

Results: A total of 93 babies were reviewed with 56.99 percent males and an average gestational age of 31 weeks 5.5 days. Subjects received a total of 221 courses of antibiotic treatment with 940 DOT equaling an AUR of 26.8 (DOT/100) patient days. Each patient received an average of 1.16 antibiotic courses with average course duration of 4.52 days. The mean baseline WBC and platelets were 12.35 and 242.58 thousand per cubic millimeter, respectively. Mean percent of bands was 7, and baseline CRP ranged from 0.2 to 223.8 milligrams per deciliter. Of the antibiotic courses, 79 percent were indicated for sepsis rule out. 41.12 percent of courses had duration greater than 48 hours, and 27.27 percent of these had positive cultures. Of the positive cultures lasting greater than 48 hours, 25 percent were indicated for sepsis rule out. A total of 88 percent of antibiotic courses had negative culture results.

Conclusion: These pre-VON initiative baseline characteristics show that antibiotic use in the NICU needs to be reduced. This baseline data indicates that an antimicrobial stewardship initiative is necessary. This will provide a baseline for post-VON initiative data to be compared to in order to assess whether the initiative was successful in reducing antibiotic use in the NICU.

Poster Title: Virologic outcomes of antiretroviral therapy in human immunodeficiency virus (HIV) infected patients following bariatric surgery: A case series

Primary Author: Sally Kassem, University of Florida College of Pharmacy, Florida; **Email:** skassem@ufl.edu

Additional Author (s):
Melissa Badowski
Christopher Taylor
Kristen Bunnell
Emily Huesgen

Purpose: Alterations in the surface area and pH of the gastrointestinal tract following bariatric surgery may impact absorption of antiretroviral therapy (ART) and ultimately, virologic suppression. Data on the efficacy and tolerability of ART in HIV-infected patients who have undergone bariatric surgery are limited or lacking for newer antiretrovirals, such as dolutegravir (DTG). The aim of our analysis was to assess virologic suppression and ART tolerability following bariatric surgery. We report a retrospective case series of 7 morbidly obese HIV-infected patients receiving ART who underwent bariatric surgery. Of the 7 patients identified with a median treatment duration of 9 months, 3 underwent sleeve gastrectomy and 2 each underwent gastric banding or bypass. Virologic suppression was achieved with 8 out of 9 ART regimens (88.9%) administered following bariatric surgery with 1 patient experiencing virologic failure due to ART-intolerance (nausea/vomiting) requiring ART change. Six patients were on DTG-containing regimens and all achieved virologic suppression. In this case series, the majority of ART regimens administered after bariatric surgery were well-tolerated and effective in achieving virologic suppression. This is the first reported data on the efficacy of DTG-containing regimens in patients who have undergone this procedure. Further studies are needed to determine the pharmacokinetic and long-term virologic effects of ART following bariatric surgery.

Poster Title: Management of hypokalemia in post open heart surgical patients on continuous furosemide infusion

Primary Author: Alexis Hochstetler, University of Florida College of Pharmacy, Florida; **Email:** lexhoss24@ufl.edu

Additional Author (s):
Nova Krzyanowski
Anit Legare
Andre McMahon

Purpose: Patients undergoing cardiac surgery are at increased risk of experiencing hemodynamic instability, defined as systolic blood pressure less than 90mmHg or heart rate less than 60 or greater than 80 beats per minute. Furosemide infusions are used to maintain urine output and prevent edema; however, furosemide can lead to hypokalemia which can contribute to hemodynamic instability. The purpose of this study is to determine the incidence of mild (3.6 to 4 millimoles per liter), moderate (3.1 to 3.5 millimoles per liter), and severe (less than or equal to 3 millimoles per liter) hypokalemia and evaluate adherence with potassium replacement protocol.

Methods: The institutional review board at Sarasota Memorial Hospital approved this retrospective chart review study. The inclusion criteria for the study were post-cardiac surgery adult patients on a furosemide infusion who had at least one potassium level drawn during the infusion. There were no exclusion criteria. Data was collected from August 2015 to March 2016. The primary outcome of the study was to determine the incidence of hypokalemia (mild, moderate, and severe) in patients on a furosemide infusion. The secondary outcomes were to assess compliance with the potassium replacement protocol which included the number of potassium replacement doses given and the number of follow-up levels obtained, and to evaluate the incidence of hemodynamic instability while patients were hypokalemic.

Results: Of the 23 patients included in this study, 20 (87 percent) experienced hypokalemia while on a furosemide infusion. Of the 126 potassium levels drawn, 87 (69 percent) were low

and required replacement: mild 56 (64 percent), moderate 29 (33 percent), and severe 2 (2 percent). Adherence with the protocol was determined as follows: 81 of 89 (91 percent) replacement doses were given, repeat levels were obtained 39 percent of the time, and the majority of follow-up levels, 33 of 39 (85 percent), remained low. Fourteen of 20 patients (70 percent) experienced hemodynamic instability while hypokalemic on furosemide infusion.

Conclusion: Based on the results, the recommendations will be to add scheduled oral potassium doses, increase the doses in the replacement protocol, and start furosemide infusions only when potassium levels are greater than 4 millimoles per liter.

Poster Title: Evaluation of a pharmacist led QTc interval monitoring program in high-risk patients

Primary Author: Rachel Huhn, University of Florida College of Pharmacy, Florida; **Email:** rhuhn@ufl.edu

Additional Author (s):
Christina Martin
William Parker

Purpose: Medications that prolong the QTc interval are commonly used in the hospital setting. Patients are often placed on two or more of these medications during a hospitalization. Pharmacists do not routinely monitor the QTc interval in high-risk patients. The purpose of this study was to implement and evaluate the effectiveness of a QTc interval informatics alert and monitoring protocol. Effectiveness will be measured by number of abnormal intervals discovered, interventions made, and outcomes of these interventions.

Methods: Using Sentri-7 Software, a dashboard item was created that would generate a real-time list of patients that are on two or more selected QTc prolonging medications. Due to limitations in code capacity, twenty formulary medications were selected that have proven or probable risk of QTc prolongation. The medications selected were those that have a high degree of severity or incidence of QTc prolongation and that are commonly used in this institution. The QTc interval, as reported by the ECG technician, was recorded daily for a period of 5 weeks. The QTc interval was calculated following Bazett's formula. Interventions were made by the pharmacist based on the QTc interval that was calculated.
If the QTc interval was between 0.43s to 0.45s for males and 0.45s to 0.47s for females, it was considered borderline and these patients received continued daily monitoring. If the QTc interval was greater than or equal to 0.45s for males and greater than or equal to 0.47s for females, it was considered abnormal and these patients received interventions as deemed clinically appropriate and continued daily monitoring. If the QTc was greater than 0.5s, in either males or females, an intervention was made in order to remove a QTc prolonging medication or reduce the dose. Patients with atrial fibrillation were excluded from this program due to the high variability of readings in these patients.

Results: Out of ninety QTc intervals calculated, 49% were in the borderline or abnormal ranges, with the majority (79%) in the abnormal range. Eight readings above 0.5 seconds were discovered which required immediate interventions. No patients suffered arrhythmias related to QTc prolongation while on this monitoring program. The average was 2.7 medications that prolong the QTc interval per patient. The medications that appeared most for all high-risk patients were levofloxacin, citalopram, and amiodarone. Twelve interventions were made as a direct result of this monitoring program and included: discontinuing medications, making therapeutic interchanges, lowering doses of medications, and adding telemetry monitoring. These interventions were 91% successful in lowering the QTc below 0.5 seconds. One patient required two interventions to achieve a QTc below 0.5 seconds.

Conclusion: This program was successful in allowing pharmacists to monitor QTc interval in high-risk patients based on the numerous abnormal readings found and interventions made. The informatics alert and monitoring protocol were integral in identifying patients at risk for arrhythmias and aiding pharmacists to make meaningful interventions. This alert and protocol have proven to be useful to direct pharmacists' attention to the most at-risk patients, decreasing the risk of serious and fatal arrhythmias. This is a new clinical opportunity for pharmacists to provide patient care that may have life-saving results. These results are hypothesis generating for future research into pharmaceutical monitoring.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Evaluative Study

Session-Board Number: 2-104

Poster Title: Computer system creatinine clearance calculation assessment

Primary Author: Vanessa Toolsie, University of Florida College of Pharmacy Orlando, Florida;
Email: vanessat@ufl.edu

Purpose: Clinicians, including but not limited to physicians, pharmacists, and nurse practitioners, routinely use healthcare facility computer systems' patient creatinine clearance (CrCl) output to assess patient renal function, and to adjust medication doses to prevent toxic overdosing or suboptimal underdosing of medications. At many facilities, both inpatient and outpatient clinicians trust facility laboratory reported CrCl as the best available estimate of patient renal function.
The purpose of this study was to compare an inpatient institution computer system's patient CrCl output to pharmacy's patient CrCl algorithm output, and to assess the potential impact of these disparities on appropriate medication renal dosing.

Methods: This research was an ethics committee approved, randomized, observational quality improvement study. Data was collected from a randomized sample of 159 patients, including male and female adult patients, and excluding pregnant and trauma patients; patients without an available computer system calculated CrCl were also excluded. Computer system Sunrise Clinical Manager's CrCl output, "SCM-CrCl", was compared to clinical pharmacy's CrCl algorithm output, "Pharmacy-CrCl".
The SCM-CrCl calculation utilized ideal body weight (IBW) within the Cockcroft-Gault CrCl calculation, and did not implement clinical adjustments for overweight or geriatric patients. The Pharmacy-CrCl algorithm also utilized IBW within the Cockcroft-Gault formula, additionally adjusting for both weight and age to aim for a more accurate patient renal function estimate. Actual body weight was used for patients weighing at least 20% below IBW, and adjusted body weight was used for patients weighing at least 20% over IBW. Serum creatinine (SCr) was adjusted via a rounding algorithm in geriatric patients aged at least 65 years.
A sample of medications which may have dangerous adverse effects if overdosed or underdosed (levofloxacin, ciprofloxacin, dabigatran, and rivaroxaban) were hypothetically assigned to each patient. The primary endpoint was cumulative SCM-CrCl renal dosing error rate, measured by total disparities between SCM-CrCl directed and Pharmacy-CrCl directed

medication doses. CrCl differences between SCM-CrCl output and Pharmacy-CrCl output, regardless of whether these differences resulted in medication dosing disparities, represented secondary endpoints.

Results: Patient demographics included 48.4% geriatrics, 58.5% males, and 41.5% females. Regarding the primary endpoint of cumulative SCM-CrCl renal dosing error rate, the individual medication dosing error rates were as follows: levofloxacin 6.92%, ciprofloxacin 8.18%, dabigatran 2.52%, and rivaroxaban 5.03%. The cumulative total SCM-CrCl medication renal dosing error rate was 22.65%, only taking these four medications into account.
Regarding secondary endpoint differences between SCM-CrCl output and Pharmacy-CrCl output, the SCM-CrCl overdose risk (percentage amount of SCM-CrCl values at least 5% above Pharmacy-CrCl) was 18.87%, and the SCM-CrCl underdose risk (percentage amount of SCM-CrCl values at least 5% below Pharmacy-CrCl) was 54.09%. SCM-CrCl output ranged from 73.36% below Pharmacy-CrCl output to 48.76% above Pharmacy-CrCl output. The Pharmacy-CrCl algorithm made adjustments for geriatric patients in 28.30% of the sample, whereas the SCM-CrCl calculation made zero adjustments in this patient subgroup to decrease the risk of geriatric medication overdose. Additionally, the Pharmacy-CrCl algorithm made adjustments for underweight patients in 3.14% of the sample, and also made adjustments for overweight patients in 52.83% the sample, while the SCM-CrCl calculation made zero adjustments in the overweight patient subgroup to decrease the risk of suboptimal renal dosing in overweight patients.

Conclusion: The computer system's SCM-CrCl led to a cumulative medication dosing error rate of 22.65%, as compared to Pharmacy-CrCl medication dosing. This statistic considers only four medications, which is just a small sampling of the multitude of medications that require renal dose adjustments; therefore, SCM-CrCl may actually lead to an even greater cumulative medication dosing error rate, which may endanger patients.
To ensure patient safety by decreasing this dangerous risk of inappropriate medication dosing, which could lead to potentially fatal adverse events, the researcher suggests that pharmacy collaborate with information technology (IT) to refine the computer system's clinical CrCl calculation algorithm.

Session-Board Number: 2-105

Poster Title: Reactivation of chronic Chagas disease post heart transplant: Implications of therapeutic management

Primary Author: Sidorela Gllava, University of South Florida College of Pharmacy, Florida;
Email: sgllava@health.usf.edu

Additional Author (s):
Julian Jolly

Purpose: Chagas disease (American Trypanosomiasis) is a disease that affects 8-11 million people worldwide and approximately 300,000 people in the United States. It is caused by infection with Trypanosoma cruzi, commonly acquired in the Americas by vectorborne transmission via insects called the triatomines that act as vectors for the protozoan parasite. The disease can also result from congenital transmission, transfusion of contaminated blood products, and transplant from an infected donor. Chagas disease has two phases, acute and chronic. Many patients with chronic Chagas disease are unaware of their infection and remain asymptomatic. Reactivation of chronic Chagas disease can occur if infected individuals become immunocompromised. There are currently only two treatment options available for Chagas disease, benznidazole and nifurtimox. Although these medications have been used for more than 30 years in Latin America, they are not FDA approved and are available in the United States only from the Centers for Disease Control and Prevention (CDC) for use under an Investigational New Drug (IND) protocol for compassionate treatment. The patient presented in this case review is a 61 year old female, originally from Brazil. Infection with T. cruzi was hypothesized to have occurred through vectorborne transmission during the time she lived in Brazil or through congenital transmission. The patient moved to the United States and developed severe chagasic cardiac disease during the 40 years she resided here. In November 2015, she received a heart transplant and was treated with anti-rejection medication, including tacrolimus. Serial PCR testing was performed weekly after the procedure to detect presence of T. cruzi genome in the peripheral blood; increasing levels were detected starting two weeks post-transplant, leading to the diagnosis of reactivation of Chagas disease. Staff at CDC's Parasitic Diseases Branch authorized the release of benznidazole by CDC's Drug Service and the patient was started on benznidazole 150 mg twice a day for 60 days. During this time, the patient was monitored closely to determine the safety and efficacy associated with

benznidazole treatment. Testing by T. cruzi PCR reverted to negative by week two of treatment and remained negative two months after completion of therapy. Adverse side effects reported by the patient included fatigue, malaise, and anorexia, which resolved four weeks post-treatment. Nausea, disorientation, and an abnormal taste were also reported and these symptoms did not resolve four weeks post-treatment. Patient also reported severe, painful, bilateral peripheral neuropathy below the knees. This side effect is frequently reported with benznidazole treatment and the severity of the symptoms sometimes leads to discontinuation of the medication or therapeutic management of the symptoms. The patient was started on gabapentin therapy and the symptoms resolved approximately 5 weeks into therapy. The patient also experienced a venous clot while on benznidazole therapy. Consideration of treatment options for this condition proved to be difficult as there is not sufficient relevant published information discussing the use of new oral anticoagulants (NOACs) with benznidazole. In order to avoid possible drug-drug and drug-disease interactions, warfarin therapy was recommended for this patient to properly monitor how it would react with the patient's anti-rejection medication as well as her benznidazole treatment. The patient completed treatment for reactivation of Chagas disease early in 2016 with no further complications, other than the ones listed above. Although most health care providers are not familiar with Chagas, there is growing awareness of the disease. This patient case presented a challenge and an opportunity for pharmacists to use their knowledge and clinical experience to determine appropriate medication management strategies.

Poster Title: Using discount drug lists to promote patient access

Primary Author: Benjamin Groves, University of South Florida College of Pharmacy, Florida;
Email: bgroves@health.usf.edu

Additional Author (s):
Nathan Thompson

Purpose: More than 1-in-6 patients report high drug costs as a barrier to medication access.1 Discount medication lists aim to remedy barriers to therapy by offering affordable prescriptions to uninsured patients at outpatient pharmacies. Furthermore, 90-day supplies of chronic medication have been attributed to high rates of adherence due to increased convenience. The purpose of this poster is to describe updating and expanding, then assessing utilization of the new Medication Access List to include more medications and offer 90-day supplies to patients at 11 outpatient pharmacies operated by the Johns Hopkins Outpatient Pharmacy (JHOP) department.

Methods: The approach we took to expanding access included: considering medications currently available in the market place on discount lists, gathering feedback from stakeholders across the health system to identify patient need, assessing long-term financial sustainability. The first step in updating the discounted list was to assess the current list offered by the Johns Hopkins Outpatient Pharmacy department and compare the market offerings of other retail pharmacies. Based on this comparison, a preliminary list of medications was created as a basis for the new medication list. Purchasing information was used to determine which medications could be offered at a discount to patients while providing financial sustainability to the pharmacy department. Finally, several medications were added despite not meeting our predefined performance measures to ensure the list reflected the needs of the patient population. Promoting the list to patients in need took place by communicating directly to patients, and to other stakeholders in the health system (e.g., physicians, nurses, social workers). Data analysis is in-progress to determine use of the new list and patient savings.

Results: A market comparison of several pharmacy chains led to a preliminary medication list of 222 items. Through an analysis of the market, an assessment of financial viability, and

stakeholder feedback, a new medication list of 207 items was developed, offering most medications in both 30- and 90-day supplies. In total, 44 medications were subtracted from the original list and 84 medications were added. Large increases were seen in the number of medications added in several categories, including a net increase in heart and blood pressure medications by 25 medications, arthritis/pain by 13 medications, and diabetes by 7 medications. Data collection is in-progress to determine use of the new list and patient savings

Conclusion: By performing a market comparison of pharmacy discount medication lists followed by a financial analysis to determine economic feasibility, patient access to commonly used generic medications was increased by updating and increasing the medications offered by the outpatient pharmacies operated by the Johns Hopkins Outpatient Pharmacy department.

Poster Title: Risk of euglycemic diabetic ketoacidosis in a patient treated with sodium-glucose co-transporter 2 inhibitor for diabetes

Primary Author: Danielle Dantuma, University of South Florida College of Pharmacy, Florida; **Email:** ddantuma@health.usf.edu

Additional Author (s):
Danielle Gagne
Pooja Patel

Purpose: This case highlights the risk of euglycemic diabetic ketoacidosis (euDKA) in a patient treated with a sodium-glucose co-transporter 2 (SGLT-2) inhibitor. The patient is a 78-year-old African American male with a past medical history of type 2 diabetes x 18 years, hypertension, nephrotic syndrome, and a history of venous thromboembolism. He has previously tried numerous sulfonylureas and insulin therapy during his course of treatment but discontinued when his diabetes was better controlled. His A1C goal was set at < 8% due to multiple coexisting chronic illnesses, and past surgical history of amputation, vascular surgery, thrombectomy, stent placement, eye surgery, and foot surgery. While taking metformin 850mg by mouth twice daily, sitagliptin 100mg by mouth daily, and pioglitazone 30mg by mouth daily, the patient still had not reached his goal A1C. With an A1C of 9.9%, canagliflozin 100 mg PO daily was prescribed by the provider. Two weeks later, pioglitazone was discontinued, sitagliptin and metformin were combined, and canaglifozin was increased to 300 mg PO daily by the clinical ambulatory pharmacist. A basic metabolic panel (BMP) and c-peptide were also ordered during the encounter; all labs came back within normal limits. During his two week follow up, the patient complained of hematuria, diarrhea, fatigue, and weakness. The urine analysis (UA) returned negative for red blood cells, however it did reveal trace ketones. BMP also revealed low bicarbonate (12 mEq/L), anion-gap metabolic acidosis (23 mEq/L), and a normal BG level (133 mg/dL). Canagliflozin was subsequently discontinued as it was the suspected offending agent for the euDKA and a repeat UA, BMP was ordered.
The Food and Drug Administration's (FDA) safety announcement released in May 2015 stated that use of SGLT-2 inhibitors may be associated with diabetic ketoacidosis (DKA). This was based on 20 reports of DKA in patients that were treated with SGLT-2 inhibitors from March 2013 to June 2014. The majority of cases were in type 2 diabetics (T2D) with only a slight

increase in blood glucose, suggesting euDKA, but not clearly defined. DKA is typically characterized by increased blood glucose levels (> 250 mg/dL), high anion gap, ketonemia, and ketonuria. According to the latest European Medicines Agency announcement on June 12, 2015, there was a total of 101 cases of DKA in T2D patients treated with SGLT-2 inhibitors reported worldwide in the EudraVigilance adverse event reporting system as of May 2015. This announcement mentions that all of the cases required hospitalization and a number of them were euglycemic with only a moderate increase in blood glucose. A meta-analysis by Erondu et al. assessed 15 randomized, controlled studies of canagliflozin to determine the incidence of serious adverse events of DKA in patients with T2D. This analysis included 17,596 patients and found that 0.07% (n=12) of the patient population experienced a serious DKA event. Additionally, only 0.017% of the patients (n=3) had a euDKA event with a blood glucose level of < 250 mg/dL. This study suggests that DKA occurs at a low rate in T2D patients treated with canagliflozin, and euDKA has an even lower rate of occurrence. Although the currently available evidence suggests that the rate of euDKA in patients with T2D is very low, patients and healthcare providers need to be educated about this issue since it is serious and life threatening. Since a precipitating factor includes the discontinuation or inadequate use of insulin therapy, ordering c-peptide routinely prior to initiating SGLT-2 inhibitors may be warranted if patient is not currently on insulin therapy. Most importantly, educating the patient to monitor for signs and symptoms of DKA such as nausea, vomiting, abdominal pain, difficulty breathing, confusion, and unusual fatigue is vital.

Poster Title: Pediatric immunization: Resources used to seek information, and their influence on the decision-making process

Primary Author: Alyson Lozicki, University of South Florida College of Pharmacy, Florida; **Email:** alozicki@health.usf.edu

Additional Author (s):
Sidorela Gllava
Jessica Johnson
Mary Soliman

Purpose: The frequency of parents refusing to vaccinate their children is continuing to increase, and misinformation from the media and other sources is perpetuating this choice. An increasing reliance on online sources for health information makes it difficult for pharmacists and other healthcare providers to dispel rumors about immunizations without knowing whether or not the information that is causing concern is accurate. The purpose of this study is to determine which resources are most frequently used by parents/caregivers seeking information about pediatric immunizations, and to evaluate how much influence these resources have on the decision-making process of parents/caregivers.

Methods: This study is a qualitative observational cross-sectional survey, and has obtained Institutional Review Board (IRB) approval. A questionnaire was created and administered to a randomly selected sample of men and women, and an agreement of consent was collected for every participant that submitted a response. In order to be included in the study, participants had to be 18 years of age or older, and incomplete responses were excluded from the data set. The questionnaire included both open-ended and close-ended questions and was administered via Qualtrics Survey Software. The study and survey were advertised through different social media posts including Facebook, Twitter, LinkedIn, and Reddit. Completed questionnaires were received via Qualtrics Survey Software and checked for completeness. Inclusion/exclusion criteria were applied, and all completed surveys were logged into an Excel spreadsheet. Preliminary statistical analyses of the data included mean average of baseline characteristics to quantify the patient population, and percent agreement with survey questions.

Results: A total of 137 responses were received, with 111 (81 percent) of the participants being female and 26 (19 percent) male. The mean age was 53 years old and 97 (70 percent) of the participants were Caucasian. Doctor's offices and medical websites were the most frequently used sources for vaccine information, with 97 (78 percent) and 87 (64 percent) respectively. Approximately 61 (45 percent) of the participants considered pharmacies as their primary source of information. Schools, friends/family, television, and newspapers were not reported to be used as a primary source of information. "Reliability of Social Media" was measured on a scale of 1 to 5, with 1 being "not reliable at all" and 5 being "very reliable". This resulted in an average rating of 1.77. Among various common concerns for participants, the most noted were concerns regarding ingredients found in vaccines and possibility of autism.

Conclusion: Parents/caregivers are turning to multiple sources to obtain immunization information. Understanding which health information resources are used by caregivers, and how much they trust that information, is crucial for health care practitioners in order to determine the most effective and empathic way of providing education. This study revealed that pharmacists are one of the most reliable and frequented sources for immunization information. This further supports how profound an opportunity exists for pharmacists to educate patients and address any potential concerns they may have regarding pediatric immunizations.

Poster Title: Sugammadex for the reversal of residual neuromuscular blockade after neostigmine administration

Primary Author: Giovanna Middlebrook, University of South Florida College of Pharmacy, Florida; **Email:** giovanna@health.usf.edu

Additional Author (s):
Deanna Boone
Shannon Weinstein

Purpose: Neuromuscular blockers are commonly used to facilitate intubation, optimize surgical conditions, and ensure fewer complications. However, studies have demonstrated that neuromuscular blockers are associated with negative and lingering side effects and can result in residual neuromuscular blockade in the recovery room. For decades, neostigmine has been utilized for the reversal of non-depolarizing neuromuscular blockers. However, a newly approved drug, sugammadex, is now also commonly used for the reversal of neuromuscular blockade induced by rocuronium and vecuronium in adults undergoing surgery. This case illustrates the potential use of sugammadex for adequate recovery of residual paralysis after neostigmine administration has resulted in residual neuromuscular blockade. The patient is an 89-year-old female admitted for a computerized tomography guided right lung biopsy due to a lung mass. She is 156.2 centimeters tall and weighs approximately 50 kilograms. She has a past surgical history of tonsillectomy and adenoidectomy, as well as thyroidectomy. She reports no prior reactions to anesthesia but states that her father once became apneic after it's administration. On the day of surgery, the patient received ondansetron 4 mg IV preprocedurally. The patient was intubated by anesthesia and received the following drugs: midazolam 2 mg IV, lidocaine 40 mg IV, propofol 100 mg IV, and rocuronium 30 mg IV. The patient also received continuous oxygen and 75 mcg of IV fentanyl spaced out into 3 doses throughout the procedure. The patient was on a continuous electrocardiogram and remained in sinus rhythm throughout the procedure. After the completion of the procedure, the patient was given neostigmine 2 mg IV, glycopyrrolate 0.4 mg IV, and ondansetron 4 mg IV. The patient was then extubated and received by the post-anesthesia care unit for recovery. Although her oxygen saturation remained at 100%, the patient remained unresponsive. She displayed no movement, was unable to speak, and displayed total sensory loss. Her score was a 35 on the

National Institutes of Health Stroke Scale and therefore a stroke alert was called. The patient was taken to receive a computed tomography scan of her head by the emergency response team. A stroke was ruled out as the scan only showed age related atrophy. The patient was transferred to the emergency department as part of the admission process and although there were hopes that she would awake, she began to deteriorate. She required more oxygen as her oxygen saturation began to trend downward, reaching 91%. The decision was made to intubate the patient and transfer her to the intensive care unit. It is at this time that the pharmacy team in the emergency department decided to intervene. Studies have demonstrated that sugammadex is faster than neostigmine in achieving recovery from rocuronium neuromuscular blockade. Sugammadex has also been shown to reduce the incidence of residual blockade compared to neostigmine in the operating room. The pharmacy team presumed that the patient was experiencing residual neuromuscular blockade and recommended the use of sugammadex for moderate block. The physician agreed to their recommendation and the family was made aware of the situation. The pharmacy team rushed to the pharmacy and retrieved a vial of sugammadex 200 mg/2 mL. The patient was given a dose of 100 mg/1 mL IV by her nurse and monitored for side effects. Within 15 minutes the patient's oxygen saturation had reached 99% and she was talking, alert, and oriented. As this case illustrates, sugammadex may have the potential to reverse persistent neuromuscular blockade, prevent intubation, and aid in patient outcomes. However, further research and clinical trials are needed to demonstrate the safety and efficacy of sugammadex for the reversal of residual neuromuscular blockade after neostigmine administration.

Poster Title: Attitudes and perceptions regarding patient centered mobile health applications supporting dynamic, interdisciplinary interventions

Primary Author: Rowshan Chowdhury, University of South Florida College of Pharmacy, Florida; **Email:** rchowdh3@health.usf.edu

Additional Author (s):
Christopher Konig
Aimon Miranda

Purpose: Mobile health (mHealth) technologies provide unprecedented opportunities for patients to actively take charge of their health. These applications give healthcare providers the ability to monitor and observe changes and trends of key markers in patients with chronic diseases. Pharmacists and physicians may capitalize on rich, longitudinal data by mining for actionable insights in the context of patient centered, interdisciplinary interventions. The purpose of this study was to assess patients', pharmacists', and physicians' attitudes and perceptions within USF Health towards mHealth applications that support dynamic, interdisciplinary interventions.

Methods: The institutional review board approved this survey assessment. Eligible participants age 18 and older were recruited and enrolled following a waiver of informed consent. Surveys were developed based on the Agency for Healthcare Research and Quality's (AHRQ) Health (Information Technology) IT Survey Compendium, administered via Qualtrics, and distributed electronically to conduct a descriptive assessment. Three different surveys were created and distributed to each study population (i.e. patients, physicians, and pharmacists). A 7-point Likert scale (1 = absolutely disagree, 7 = completely agree) was utilized to address areas of use related to willingness and ability, comfort, frequency, and sharing of information. The primary outcome was to provide an analysis of these survey questions. Statistical analysis was conducted in Microsoft Excel 2016 with Real Statistics Resource Pack add-in.

Results: Among the 26 total participants, 44 percent of physicians are completely willing to recommend a mHealth application (n=16), 100 percent of patients agreed they are willing to use an mHealth application to collect their health information (n = 4), and 83 percent of

pharmacists feel that they have the proper knowledge to interpret and evaluate mHealth data (n=6). The Mann-Whitney U test was used to compare physician and pharmacist willingness to recommend applications, access data, use and input data, and allow patients to have more responsibility for their health. There were no significant differences in median response to each item (U and U critical values were 38 and 21, 46 and 21, 38 and 21, and 39.5 and 21, respectively). When asked about their ability to use mHealth applications, no significant difference was found in any of the questions on the survey related to this measure including: understanding what mHealth is and why it is important, having the proper knowledge to evaluate data from a mobile application, and believing their patients have adequate health literacy to use mHealth (U and U critical values were: 32.5 and 21, 34.5 and 21, and 22.5 and 21).

Conclusion: These results indicate strong positive attitudes and perceptions towards mHealth applications in clinical practice with a strong willingness and ability to partake in such an opportunity by both physicians and pharmacists.

Poster Title: Evaluation of timing of culture collection to determine need for antibiotic stewardship program at a small regional health center.

Primary Author: Sarah Cooper, University of Kansas, Kansas; **Email:** s498c201@ku.edu

Additional Author (s):
Molly Pham

Purpose: At least two million people become infected with antibiotic resistant bacteria annually. According to the CDC, some of the best ways to combat such resistance are to order cultures before antibiotics are given, and start drugs promptly. Make sure indication, dose, and expected duration are specified in the patient records. It is also important to reassess antibiotic treatment within 48 hours and adjust the antibiotic if necessary or stop the antibiotic if indicated. This study was done to review procedures at Newman Regional Health in terms of culture collection to determine the need of an antibiotic stewardship program.

Methods: Retrospective review of inpatient charts. The inclusion criteria were patients who received one or more of the following antibiotics over the course of March 1st – August 31st 2016:
Ampicillin, Ampicillin/Sulbactam, Nafcillin, Zosyn, Cefazolin, Ceftriaxone, Cefepime, Aztreonam, Meropenem, Ertapenem, Levofloxacin, Doxycycline, Azithromycin, Gentamycin, Vancomycin, and Daptomycin.
The exclusion criteria were patients under the age of 18; cultures drawn more than 7 days before or after antibiotic therapy; and patients seen as outpatient treatment, same day surgeries and wound care. There were 33 cases of patients whose files could not be accessed in MediTech because their last stay fell out of the previous 6 months range at the time of information retrieval.
The study entailed whether or not cultures were collected and if so, were cultures drawn before or after start of antibiotic regimen. Length of antibiotic use was also recorded. From this information, estimated costs were calculated based on pharmacy contract prices obtained on September 22nd, 2016. Each estimated dose was calculated by cost per vial plus an overall charge of $50 for the IV supplies. Estimated total and average cost per admission were based

on the assumption that current dosing guidelines from Lexicomp were followed. Appropriate changes to antibiotic therapy based on the cultures were assumed in terms of de-escalation and discontinuation. A further study would need to take place to test these assumptions.

Results: There were a total of 684 admissions that fell under the study parameters. The total number of antibiotics used was 1,021 which averaged to 1.49 antibiotics per admission. Out of the sixteen antibiotics monitored, six of them were used more than 10% of the time. These were: Ceftriaxone (34.94%), Levofloxacin (19.88%), Cefazolin (16.52%), Azithromycin (16.37%), Vancomycin (16.08%), and Zosyn (12.57%). All of these antibiotics have broad-spectrum coverage, except for Vancomycin. The estimated total cost was $344,008.53. The estimated average cost per admission ranged from Ampicillin at $64.40 to Daptomycin at $2,343.03 per admission. Out of 684 admissions, 115 (17%) did not receive any cultures. Out of the 684 admissions, 47 (7%) cases did not have a blood culture drawn. Of the cases where blood cultures were drawn, 324 (47%) were taken before start of antibiotics. Out of these cases, 313 (46%) cases had blood cultures drawn after start of antibiotics. Other cultures included CSF, joint fluid, nasal/respiratory panels, sputum, stool, urine, and wound samples. Of the 684 cases, 224 (33%) did not have these cultures collected. Of those collected, 265 (39%) were collected before start of antibiotics while 195 (29%) cases had these cultures drawn after start of antibiotics.

Conclusion: Almost all of the antibiotics used were broad spectrum or powerful antibiotics. Although most antibiotic regimens involved culture samples, less than half were drawn before start of therapy. This conclusion does not account for prophylactic antibiotic use like surgical procedures or labor which could skew the results. However, this conclusion would still indicate a higher risk for antibiotic resistance. An antibiotic stewardship program would monitor culture collection as well as verify that antibiotics are used appropriately by verifying the culture results and either de-escalating or discontinuing inappropriate therapies. These actions would lower the risk of antibiotic resistance and improve care.

Poster Title: Evaluation of sleep agent use for the treatment of insomnia in suicidal patients

Primary Author: Georgia Luchen, University of Kansas School of Pharmacy, Kansas; **Email:** gina.galanou@gmail.com

Additional Author (s):
Manpreet Kaur
Brittany Melton
Amad Din
Karen Moeller

Purpose: Insomnia has been linked to suicidal thoughts and behaviors. As a result, it has been theorized that effectively treating insomnia can potentially lead to a reduction in suicidal risk. This study sought to evaluate the prescribing patterns for sleep medications in the adult psychiatric unit between suicidal and non-suicidal patients.

Methods: A retrospective chart review was conducted for patients admitted to the adult psychiatric unit of a Midwestern academic hospital between July 1st 2014 and June 30th 2015. Patients were identified through the Healthcare Enterprise Repository for Ontological Narration (HERON) database. Patients were included in the study if they were 18 years of age or older, and had a length of stay between 2 and 14 days. Data collected were compared between suicidal and non-suicidal patients, and included: patient demographics, suicidal attempts, behaviors or ideation, primary discharge diagnosis, and the number and class of sleep medications patients received prior to admission, during admission and at discharge. Data analysis was conducted using SPSS v.23. Chi-square was utilized to assess differences in race, diagnosis, gender, and medication class, while independent t-tests were used to assess differences in length of stay, age, and number of medications, between suicidal and non-suicidal patients with an a-priori a=0.05. The institutional review board at the University of Kansas Medical Center approved the study.

Results: Four hundred and fifteen patients met the inclusion criteria for this study, of which 262 (63.1%) had an admission for suicidal ideations or behaviors. Demographics for suicidal and non-suicidal groups varied significantly for race (71.8% vs 60.1% white for suicidal and non-

suicidal, respectively; p=0.02), and length of stay (6.43 days vs 4.87 days; p < 0.01, suicidal and non-suicidal, respectively). Suicidal patients were more likely to have a primary diagnosis for mood or anxiety disorders (p < 0.01, 0.04, respectively), while non-suicidal patients were more likely to have a thought disorder primary diagnosis (p < 0.01). The most commonly prescribed sleep agents amongst all patients during hospitalization were sedating antidepressants (69.1% in suicidal and 64.1% in non-suicidal patients), benzodiazepines (31.3% and 39.9% respectively), and sedating antihistamines (24% and 22.9%, respectively). In both groups, the number of medications received at discharge was larger than the number received prior to admission (0.85 vs 0.43 for suicidal, and 0.66 vs 0.36 for non-suicidal; p < 0.01 for both groups). Upon discharge suicidal patients were prescribed a larger number of sleep agents than non-suicidal patients (0.85 vs 0.66; p < 0.01), and class-wise received a greater number of sedative antipsychotics (7.3% vs 2.6%; p=0.046).

Conclusion: Overall, use of sleep medications was similar between suicidal and non-suicidal patients during hospitalization. However, suicidal patients were more likely to continue on their sleep medication at discharge. This may suggest suicidal patients' insomnia symptoms were more prevalent or severe during hospitalization and required on-going treatment. Regardless of suicidal status, patients on average received more than one sleep agent during admission and were prescribed significantly more sleep medications upon discharge than prior to admission. Further studies are required to evaluate the effectiveness of sleep medications in suicidal patients and their potential in decreasing suicidal risk.

Submission Type: Descriptive Report

Session-Board Number: 2-113

Poster Title: Evidence for compounded topical agents used for the treatment of neuropathic pain

Primary Author: Angela Sanders, University of Kansas School of Pharmacy, Kansas; **Email:** asanders@ku.edu

Purpose: Approximately 3.8 million patients in the United States suffer from neuropathic pain. Despite the availability of numerous oral options, adverse events such as drowsiness, dizziness, impaired cognition, and nausea often limit their use. In addition, less than 50% of patients with neuropathic pain experience satisfactory pain relief, and over 45% of these individuals already take two or more medications to manage their pain. This project assessed the clinical evidence for use of compounded topical agents for the treatment of neuropathic pain as an alternative to oral products.

Methods: An initial PubMed search was conducted to identify commonly used topical pain medications for neuropathic pain. From the search, medications used most frequently in studies were determined to be ketamine, amitriptyline, gabapentin, and baclofen. A second literature search was conducted within the databases of the University of Kansas Library, as well as Google Scholar, with search terms "neuropathy" or "neuropathic pain" plus "topical" and/or "compounded" both with and without medication names through the date of July 21, 2016. There were 26 studies identified to be relevant to the topical treatment of neuropathic pain with one or more of the four medications studied. Elements of each study were categorized by number of medications in product, the medication(s) and their concentrations, study design, number of patients studied, indication, dosing and administration, duration of treatment, and safety. The data was then analyzed to determine whether these elements impacted the efficacy of the product studied.

Results: The efficacy was conflicting for three of four drugs with exception of gabapentin which had 60/60 patients report improvement in four non-randomized studies. There were 11 studies that evaluated ketamine with varying concentrations. Ketamine/amitriptyline combinations were assessed in five trials with three times the number of patients studied for the other topical therapies, although efficacy was low (140/700).

Medical conditions varied between and within studies. Post-herpetic neuralgia patients from eight trials responded consistently (146/172). Vulvodynia/vestibulodynia (73/73) and complex regional pain syndrome (27/27) exhibited consistent results, although only two studies included each condition. Chemotherapy-induced neuropathic pain was studied in three trials with the largest patient population, although efficacy was low (209/671).

Formulations differed by medication(s) and number of medications, concentrations of medication(s), compounding vehicle used (lipoderm and pluronic lecithin organogel were the most common), and properties of penetration enhancers used. The definition of efficacy differed between studies based on reduction of a varying number of symptoms including pain, numbness, and tingling. The only study with an oral comparator (gabapentin) determined topical ketamine to be non-inferior. At least some symptom improvement was reported in 43% of patients overall. Patients reported minimal side effects, with mild skin irritation being the most common.

Conclusion: Topical gabapentin generated the most consistent results compared to the other three medications in addition to medication combinations. At this time, the clinical evidence is inconclusive and cannot be used to predict a benefit for any of the four medications used topically; however, adverse events were minimal among all of the evaluated products.

Poster Title: Discontinuation rates of oral P2Y12 inhibitors in end-stage renal disease patients on chronic dialysis

Primary Author: Margaret Hansen, University of Kansas School of Pharmacy, Kansas; **Email:** mlhansen@ku.edu

Additional Author (s):
Rafia Rasu
Busuyi Olotu
Nishank Jain

Purpose: The purpose of this study is to describe the characteristics and medication discontinuation rates of patients with end-stage renal disease (ESRD) in an academic medical center who have been prescribed clopidogrel, prasugrel or ticagrelor. Furthermore, it was hypothesized that physicians would have prescribed prasugrel or ticagrelor more frequently than clopidogrel to patients with established cardiovascular disease due to the reported superior antiplatelet effects of the newer agents. Patients with ESRD and on dialysis are commonly excluded from clinical trials for these medications, leaving clinicians with little guidance for the use of oral P2Y12 inhibitors in dialysis patients.

Methods: The electronic medical records (EMR) of 85 ESRD patients on dialysis who were prescribed clopidogrel, prasugrel or ticagrelor between July 20, 2011 and December 31, 2015 were reviewed to collect baseline characteristics and determine medication discontinuation dates. Baseline characteristics included age, sex, race, body mass index, comorbid conditions, current medications and history of cardiovascular disease. A medication was considered prematurely discontinued if the patient was on the medication less than 330 continuous days following percutaneous coronary intervention (PCI) with a drug eluting stent. Patients with a history of myocardial infarction, coronary artery bypass graft (CABG), coronary stent, any amputation or diagnosis of coronary artery disease prior to the inciting event requiring medication with an oral P2Y12 inhibitor were considered to have established cardiovascular disease. Ischemic stroke or transient ischemic attack (TIA) were excluded from the definition of established cardiovascular disease because prasugrel is contraindicated in these patients. Outcomes included all-cause death, gastrointestinal bleeding rates and major adverse cardiac

events (MACE). MACE was defined as occurrence of new coronary artery stent, heart valve replacement, CABG, any amputation and all-cause hospitalization following the inciting event. Data analyses were performed using IBM SPSS Statistics Version 23. An alpha value was set a priori at less than 0.05 to be statistically significant.

Results: Of 848 ESRD patients on dialysis who were prescribed an oral P2Y12 inhibitor between 2011-2015, 785 were prescribed clopidogrel (92.6%), 46 were prescribed prasugrel (5.4%) and 17 were prescribed ticagrelor (2.0%). From the 63 EMR of patients who received either prasugrel or ticagrelor, only 48 EMR contained adequate information to collect all required baseline and outcome data. A convenient sample of 54 EMR of ESRD patients on dialysis was randomly selected from the 785 EMR of patients who received clopidogrel, and yielded 37 complete clopidogrel entries. The charts of 85 patients, or 10% of ESRD patients on dialysis who were identified to have been prescribed an oral P2Y12 inhibitors, were reviewed.
No statistically significant differences were observed in baseline characteristics or outcomes between the clopidogrel and prasugrel/ticagrelor groups. However, there was a difference in medication discontinuation rates between the clopidogrel group (13.5%) versus the prasugrel/ticagrelor group (35.4%) (p=0.022). While more patients prescribed prasugrel or ticagrelor met the definition of established cardiovascular disease (91.7%) compared to the clopidogrel group (81.1%), these findings were not statistically significant (p=0.20).

Conclusion: The large majority of ESRD patients on dialysis who needed antiplatelet therapy were prescribed clopidogrel, indicating that it is the medication that prescribers are most comfortable using in dialysis patients. Reasons for discontinuation of prasugrel or ticagrelor were not captured in this study, but could include high cost, lack of insurance coverage, or higher rates of adverse effects such as bleeding. Larger studies are needed to evaluate contemporary use of P2Y12 inhibitors in dialysis patients and investigate their association with clinical outcomes.

Poster Title: Comparing allogeneic red blood cell transfusion practices before and after provider education

Primary Author: Anna Boyd, University of Kansas School of Pharmacy, Kansas; **Email:** annaboyd@ku.edu

Additional Author (s):
Shawn Giess
January Fields-Meehan
James Meier
William Cadoret

Purpose: The practice of allogeneic red blood cell transfusion, although common, differs greatly amongst providers. Although potentially lifesaving, transfusions also come with significant health risks. Recent guidelines suggest that restrictive use of transfusion (only patients with hemoglobin values 8 grams per deciliter (g/dL) or less) decreases harm and improves patient outcomes. Education was provided to prescribers at Hays Medical Center regarding these guidelines. In order to identify compliance, and to evaluate the effect of provider education on transfusion practices, a retrospective analysis was begun to identify provider trends in ordering blood transfusions at Hays Medical Center from 2012 to 2016.

Methods: Following the guideline updates for red blood cell transfusions, education was administered to prescribers by physician and pharmacy staff. This education, begun in February 2014, highlighted the appropriate hemoglobin thresholds to initiate transfusion in order to ultimately reduce the total number of transfusions and to ensure a less than five percent monthly and annual incidence of transfusion in patients with a hemoglobin value of 9 g/dL or greater. To analyze the effects of provider education on transfusion practices, patient charts from January 2012 to June 2016 were retrospectively analyzed via retrieval from the hospital's MEDITECH electronic health record system. Records of those patients who received blood transfusions were retrieved and the hemoglobin values at which transfusion occurred were subsequently recorded. Data were analyzed for monthly and yearly trends. The total number of transfusions per month and year were also calculated. Data were analyzed for the two years

prior to the intervention and for two years following the intervention for comparative purposes.

Results: The total number of transfusions decreased yearly, with 788 transfusions in 2012, 772 in 2013, 747 in 2014, and 679 transfusions in 2015. From January to June of 2016, 296 transfusions were completed. Additionally, following prescriber education, the percentage of transfusions at elevated hemoglobin values decreased. In 2012 and 2013, 3.04% and 3.10% of transfusions occurred at hemoglobin values greater than or equal to 9 g/dL, respectively. In 2014, transfusions given at hemoglobin values 9 g/dL or above accounted for 5.20% of the total transfusions. For every month after June 2014, the incidence of transfusion for a hemoglobin 9 g/dL or greater was below the 5% goal. In 2015, 2.50% of transfusions occurred at hemoglobin values at or above 9 g/dL, with only one month above the 5% goal. In 2016, for the data analyzed between January and June, transfusions occurring at a hemoglobin 9g/dL or greater accounted for only 1.40% of the total yearly transfusions, with zero months above the 5% threshold.

Conclusion: Physician- and pharmacist-driven education proved efficacious in altering allogeneic red blood cell transfusion practices in prescribers at Hays Medical Center. Collaboration between multiple disciplines can provide improved patient and hospital outcomes and may be considered for future interventions.

Poster Title: Institution wide evaluation of medication overrides from automated medication dispensing cabinets after process improvement changes: One year later

Primary Author: Chenshan Zhou, University of Kansas School of Pharmacy, Kansas; **Email:** chenshanzhou@gmail.com

Additional Author (s):
Megan Penner
Jeff Pierce
Heather Smith
Patrick Parker

Purpose: Overrides from medication dispensing cabinets are necessary for emergent and urgent patient care, but should be limited to ensure patient safety and drug security. It was found that there is little consensus across the region for standards of overrides. Lawrence Memorial Hospital is a 176-bed community hospital using automated dispensing cabinets for the bulk of patient medications. Lawrence Memorial Hospital revised its medication override policy by limiting the overridden medications to those only approved by the institution as safe for emergent use. Limiting the number of medications should reduce the total number of overrides and improve patient safety.

Methods: A Plan-Do-Check-Act cycle was used for process improvement. A previous study provided the baseline for the cycle of improvement by providing definitions of appropriate and inappropriate overrides as well as a frequency of occurrence by nursing unit. Improvement plans included establishing a list of approved override medication approved by the Medication Use Team and the Pharmacy and Therapeutics committee and only allowing charge nurses access all of the institution's formulary for emergency override. The available reasons for override include removing refrigerated med, Douglas Fire and Med, kits, medication order reviewed by qualified healthcare professional, urgent situation, and enter free text reason. Medication overrides were approved for emergency use for any product in the cabinet. Retrospective data review was collected from August 1, 2016 to August 15, 2016. The ratio of overrides to total doses removed was compared to the previous improvements and baseline project. The overrides were stratified by reason for override and nursing unit. Nursing unit data

were stratified by "inappropriate" (if there was either no physician order, no pharmacist verification, or if they were assessed by the pharmacist as not meriting override) or "appropriate" (if all criteria were met). Overrides for supplies, kits, and refrigerator access to obtain IVs are also deemed appropriate so excluded from the total count because these are not a concern.

Results: In the two week period examined, there were 275 (1.7 percent) overrides out of 15,940 removals (baseline 1079, 5 percent, overrides out of 21,645 removals). Overall, the number of medication overrides decreased as did the percentage of medication overrides compared to previous years after process improvement changes. Of these overrides, 190 (86 percent) were appropriate compared to a baseline of 858 (81 percent). Thus, only 30 (14 percent) were inappropriate compared to a baseline of 198 (19 percent).

The number of data excluded increased from baseline of 23 to 55. All of the excluded data were due to no medication removal found, versus previous year's data included both no medication removal found and incomplete patient information and thus inability to assess appropriateness of medication override removal.

A chi squared test was used to evaluate statistical significance. With 1 degree of freedom, the critical value is 2.706 for a probability 0.1. The chi squared value (3.24) exceeds the 2.706 indicating departure from expectation. The chance of this result occurring by change is less than 7 in 100. We can be 93% confident that our changes are due to the process improvements.

Conclusion: The process improvement changes of limiting the number of medications reduced the total number of overrides and improve patient safety. All overrides threaten patient safety by omitting safety parameters in place, such as avoidance of look-alike/sound-alike drugs and multiple drug strengths. Areas with less critically ill patients, such as internal medicine, had fewer overrides, compared to ICU, due to decreased emergent situations with the exception of LDR. The list of inappropriate medication overrides and the current list of appropriate medications for overrides will be presented to the Medication Use Team for assessment and further improvements.

Poster Title: Trazodone utilization for insomnia in the adult psychiatric hospitalization

Primary Author: Manpreet Kaur, University of Kansas school of Pharmacy, Kansas; **Email:** manpreet.sandhu91@gmail.com

Additional Author (s):
Georgia Luchen
Brittany Melton
Amad Din
Karen Moeller

Purpose: Trazodone, a sedating antidepressant, is commonly used off-label for the treatment of insomnia. However, there is little clinical evidence to support it use as a sleep agent. This study evaluated prescribing practices related to trazodone utilization for the treatment of insomnia in an adult inpatient psychiatry unit.

Methods: A retrospective chart review was conducted using inpatient medical records from a Midwest academic medical center. Patients were identified through The Healthcare Enterprise Repository for Ontological Narration (HERON) database. Patients included in the study were at least above 18 years of age or older, prescribed trazodone, and admitted to the inpatient psychiatry unit between July, 1 2014 to June, 30 2015. Patients were excluded if their hospital length of stay was less than two days or greater than 14 days or if they were prescribed trazodone for the treatment of depression. Indications for trazodone were evaluated for trazodone's use if the dosage was above 200 mg to determine study inclusion. Records were reviewed for demographics, dosages, regimens (scheduled versus as needed), discharge diagnosis, and other hypnotic medications. Additionally, trazodone use prior to admission, during hospitalization, and at the time of discharge were evaluated. Data analysis was conducted using SPSS v.23. Descriptive statistics were used for continuous values, and chi-squared analysis was done to assess trazodone utilization prior to admission and at discharge. Statistical significance was defined as $p < 0.05$. This study was approved by the University's institutional review board.

Results: Four hundred and fifteen patients were admitted to the psychiatry unit between July, 1 2014 to June, 30 2015. Demographics for both trazodone and non-trazodone groups varied based on age, gender, race, length of stay, and primary discharge diagnosis. Overall, 248 patients (58%) were prescribed trazodone as a hypnotic during hospitalization. Only 44 patients (17.7%) had a trazodone prescription prior to admission. However, trazodone was prescribed to an additional 204 patients (82.2%) during hospitalization. Upon discharge trazodone was prescribed to 128 patients (51.6%), despite only 31% of patients receiving trazodone having a documented insomnia complaint ($p < 0.05$). On average, each patient was prescribed at least two hypnotics, for instance, trazodone, benzodiazepines, melatonin, etc. Trazodone was most commonly started on the first day of hospitalization.

Conclusion: This study found high utilization of trazodone among psychiatric patients. There was a significant increase in trazodone prescribing at discharge as compared to prior to admission. Based on limited clinical evidence regarding trazodone usage for insomnia, the overall utilization of trazodone should be evaluated.

Submission Type: Evaluative Study

Session-Board Number: 2-118

Poster Title: Intravenous iron sucrose order set compliance within a multi-hospital regional health system.

Primary Author: Jacqueline Pyle, University of Kansas School of Pharmacy, Kansas; **Email:** jmpyle10@gmail.com

Additional Author (s):
Breanna Clark
Paige Melling
Leigh Ann Milburn
Sarah Roth

Purpose: An electronic order set is available to prescribers within Saint Luke's Health System (SLHS) to ensure intravenous (IV) iron sucrose is ordered and administered in a cost-effective and safe manner. When IV iron sucrose is ordered within the SLHS computerized physician order entry (CPOE) system, the verifying pharmacist ensures each of the required elements within the order set have been completed by the prescriber. The purpose of this study was to conduct a medication utilization evaluation to ensure IV iron sucrose is being ordered in compliance with parameters set forth within the SLHS order set.

Methods: This study was granted exemption by the health system's investigational review board. A retrospective patient chart review was performed on IV iron sucrose orders that were placed between July 2015 and December 2015. A random sample of 100 inpatient orders, generated electronically, was selected for evaluation across four hospitals. The selected orders were divided proportionally amongst the four hospitals relative to patient volume. Outpatient orders and orders for hemodialysis patients were excluded given that separate order sets are utilized for these populations. Patient charts were reviewed using the electronic health care record to collect the following: location of patient, dose and frequency ordered, order set utilization, prescriber, verifying pharmacist, estimated glomerular filtration rate (eGFR) and corresponding stage of chronic kidney disease, presence of contraindications, diagnosis/indication for IV iron sucrose, and laboratory values as follows: hemoglobin, serum ferritin, and transferrin saturation (Tsat). The primary outcome measured was overall

compliance rate with adherence to order set criteria. Secondary outcomes measured included reasons for noncompliance and compliance rates categorized by hospital location.

Results: Of the 100 IV iron sucrose orders evaluated, 15 were originally determined to be noncompliant with the order set, which equaled an overall compliance rate of 85 percent. Of those 15 noncompliant orders, six orders were determined to be clinically appropriate upon further independent review by a pharmacy clinical coordinator despite exceeding the 72 hour time parameter set forth on the order set for obtaining labs prior to IV iron sucrose administration. This led to an overall adjusted compliance rate of 91 percent. Of the remaining nine noncompliant orders, four orders did not have any or all of the necessary labs drawn to meet criteria, four orders consisted of a relative contraindication (uncontrolled bacterial infections), and one because it had lab values that did not warrant IV iron sucrose usage. Compliance rates categorized by hospital location were 92 percent for the largest urban hospital, 90 percent for the largest suburban hospital, and 90 percent at each of the two smallest suburban hospitals.

Conclusion: Compliance with the IV iron sucrose order set within SLHS was 85 percent. The exclusion of six additional orders originally deemed noncompliant but later deemed to be clinically appropriate, led to an overall adjusted compliance rate of 91 percent. Recommendations for potential areas of improvement in the future included implementing a hard stop within the CPOE system which would prevent physicians from ordering IV iron sucrose without the appropriate iron studies being available. Also, including the iron study results within the order verification screen so that verifying pharmacists would be able to view those results immediately.

Submission Type: Evaluative Study

Session-Board Number: 2-119

Poster Title: Evaluation of Kansas pharmacy students' perspectives on physician-assisted suicide and the demographic factors that influence those perspectives

Primary Author: Chelsea Zipse, University of Kansas School of Pharmacy, Kansas; **Email:** clzipse@gmail.com

Additional Author (s):
James Kleoppel
Barbara Woods

Purpose: A controversial issue in pharmacy practice today is physician-assisted suicide, which is defined in this study as self-administration of a lethal drug dosage prescribed by a physician. Currently physician-assisted suicide is legal in five states. Four states have legalized it due to legislation, and one state has legalized it via a court ruling. A survey was conducted to determine general views and demographic factors that may influence the opinions of pharmacy students in Kansas, a state where physician-assisted suicide is not currently legal.

Methods: This survey was sent out to 603 Kansas pharmacy students. Two hundred and eighty one students submitted surveys with 279 surveys having completed responses, leading to a response rate of approximately 46 percent. The survey assessed demographics, including: gender, age, religion and the level of religious belief, political views, enrolled year in pharmacy school, current and/or past pharmacy work experience and the pharmacy setting, and whether students knew of or have witnessed a family member and/or friend suffering from a terminal illness. The other questions asked related to students' opinions on physician-assisted suicide, such as the morality of suicide, under which medical conditions or circumstances physician-assisted suicide should be limited to, willingness to dispense a lethal drug dosage, et cetera. The survey was administered and analyzed using REDCap (research electronic data capture). Means were calculated and responses for each question were compared between the different demographic groups to determine which factors had the greatest influence on a variation from the overall mean response. The institutional review board of the University of Kansas approved this study.

Results: It was found that 50 percent of pharmacy students would support legalizing physician-assisted suicide for terminally ill patients in Kansas. Twenty four percent of students said their support would be conditional, and 26 percent said they would not support the legalization. Several demographic factors were found to be more or less in favor of physician-assisted suicide, with a 10 percent difference or more in their categorical mean from the overall mean response. Students were more likely to support a bill legalizing physician-assisted suicide from the overall mean if atheist (35 percent more likely) and liberal in their political views (24.1 percent more likely). Students were less likely to support the legalization if Christian (10.5 percent less likely) or considered themselves to be religious (23.3 percent less likely) or very religious (24.3 percent less likely). Students were less likely to support the legalization if conservative (15.5 percent less likely) or very conservative in their political views (39.7 percent less likely). First year pharmacy students were 17.8 percent less likely to support the legalization.

Conclusion: This study found that the majority of Kansas pharmacy students would support legalizing physician-assisted suicide. The most influential demographic factors that determined views towards physician-assisted suicide were: being 30 years of age or older, religion and the level of religious belief, political views, enrolled year of pharmacy school, and current and/or past pharmacy work experience and the pharmacy setting. However, due to the small sample size, further research is needed to establish more comprehensive results.

Submission Category: Geriatrics

Submission Type: Evaluative Study

Session-Board Number: 2-120

Poster Title: University of Kansas geriatrics champions program (GCP): Assessment of interprofessional competence

Primary Author: Jiabao Christina Yuan, University of Kansas School of Pharmacy, Kansas; **Email:** christinayuan92@gmail.com

Additional Author (s):
Crystal Burkhardt
Shelley Bhattacharya

Purpose: The purpose of this study was to investigate if knowledge gained by learners during the Geriatrics Champions Program (GCP) 1) was applied in advanced pharmacy practice experiences (APPE), 2) equipped students with the ability to communicate with geriatric patients comfortably, and 3) prepared students for interprofessional teams. Additionally, information for potential areas of program improvement was obtained.

Methods: GCP was a 12 month, 6 professional curriculum designed to teach geriatric content in an interprofessional manner using a team-based learning format at the University of Kansas Medical Center.
A retrospective survey study was developed using a likert scale to assess the eight learning domains achieved with the GCP program. The surveys were completed online through Google Forms, and answers were 100% anonymous without any link to the preceptor. Preceptor practice background was collected, which included years of practice, setting, and scope of geriatric practice.
Inclusion criteria included preceptors of GCP students during August-September 2016. The exclusion criteria included students directly involved with the research process as well as students who participated in an additional geriatrics elective.
The intervention group included preceptors of students who had completed the GCP program in 2015-16 and the control group included preceptors of students who were randomly selected in the months of August-September 2016 and had not completed the GCP program. Once both groups were established, separate surveys were emailed to preceptors of the identified students.

The primary outcome measured the demonstration of eight learning domains and the secondary outcome measured specific areas for potential improvement while on APPEs. Descriptive statistics and student T-Test of quantitative data were employed to report trends in responses.

This study has been approved by the institutional review board (IRB).

Results: There were a total of 23 (42.6%) responses in the intervention group and 19 (35.2%) responses in the control group out of 54 surveys sent to both groups. Preceptors came from a variety of backgrounds including critical care, corporate management, ambulatory care, and research. Preceptors indicated medication management as the most prevalent learning domain as well as the strongest area for both groups. However, the exposure and opportunities students had while on rotation were lacking in a few of the learning domains for both groups such as special considerations in geriatric care, cognitive, affective, and behavioral health, end of life care, and ambulatory care of older adults. Preceptors also identified complex/chronic illnesses in older adults and end of life care as the weakest areas for students in both groups. The intervention versus control group showed differences in the ability to participate on an interprofessional team [21 (91.3%) and 16 (84.2), respectively, p=0.9695], comfort in geriatric patient communication [14 (60.9%) and 8 (42.1%), respectively, p=0.6227], and previous possession of clinical knowledge regarding geriatric patients [14 (60.9%) and 12 (63.2%), respectively, p=0.6405].

Conclusion: Our analysis showed similar conclusions with primary and secondary outcomes across groups; however, the intervention group had higher percentages of interprofessionalism and geriatric communication. Due to small sample size, statistical differences did not emerge in this study. These results furthered assessment insight through the preceptor's perspective on students' abilities and the correlation with interprofessional programs, which can inform educational governing bodies such as the Center for the Advancement of Pharmacy Education (CAPE) and the Accreditation Council for Pharmacy Education (ACPE). Further data from additional years of study or input from other professions would strengthen the results of this study.

Submission Type: Evaluative Study

Session-Board Number: 2-121

Poster Title: Evaluation of enoxaparin dose adjustments in renally impaired or obese patients in a medium-sized community hospital

Primary Author: Alaina Linafelter, University of Kansas School of Pharmacy, Kansas; **Email:** lainiej7@gmail.com

Additional Author (s):
Patrick Parker
Christina Graham
Christina Lawrenz
Derrick Eddy

Purpose: Enoxaparin is a commonly used anticoagulant for venous thromboembolism (VTE) prophylaxis in the inpatient setting with benefits such as reduced laboratory monitoring and a relatively quick onset of action. The Pharmacy & Therapeutics (P&T) Committee created guidelines for dosing at-risk populations with renal impairment (bleeding risk from reduced clearance) or obesity (thrombosis risk from inadequate dosing). Pharmacists have a collaborative practice agreement to adjust for renal dosing, but not for obesity. The purpose of this study was to determine the frequency and accuracy of dosing adjustments in these at-risk populations.

Methods: All inpatients age 18 or older with an order for enoxaparin over a three-month time frame were included in this retrospective, chart review. Patients receiving enoxaparin for an indication other than VTE prophylaxis or patients currently receiving dialysis were excluded. Patient's concurrent weight, height, and estimated creatinine clearance were used to evaluate the initial doses ordered by the practitioner, the doses verified by the pharmacist, and the dose adjustments made later in therapy.

P&T guidelines recommend enoxaparin 30 mg subcutaneously daily for individuals with renal impairment, defined by an estimated creatinine clearance less than 30 mL/min, and a dose of 0.5 mg/kg subcutaneously daily for obese individuals, defined by a body mass index of greater than or equal to 40 kilograms per square meter.

The primary outcome measure was the percentage of patients whose renal function or body mass index warranted dosing alterations per P&T guidelines. The secondary outcome measures

were the percentages of accurate dose modifications made by the pharmacist or prescriber. The study received an expedited approval from the Institutional Review Board and P&T committee.

Results: A total of 450 encounters were screened for this study. Sixty-six patients were excluded. Of the remaining 384 encounters, 111 patients met criteria for dose alterations per P&T guidelines. The patients were further divided into those with renal impairment (48, 12.5 percent), obesity (66, 17.2 percent), or both (3, 0.8 percent). Overall, 56.3 percent of patients with renal impairment and 25.8 percent of obese patients had doses correctly modified according to P&T guidelines.

The prescriber accurately modified the first dose in 5 (10.4 percent) of the renal patients and 10 (15.2 percent) of the obese patients. Pharmacists correctly modified the doses of an additional 22 (45.8 percent) patients with renal impairment, but incorrectly modified the dose for 1 (2.1 percent) patient. Pharmacists correctly modified the doses of an additional 7 (10.6 percent) obese patients, but incorrectly modified 6 (9.1 percent).

Estimated creatinine clearances improved from initial calculations for 16 (33.3 percent) of the 48 renally impaired patients to the point where dose adjustments would no longer be required. Of these 16 patients, only 5 received dose adjustments based on their initial creatinine clearance, and 2 of these 5 patient's doses were readjusted to normal following their improvement in renal function.

Conclusion: A significant number of patients required dose adjustments of enoxaparin for renal impairment (12.5 percent) and obesity (17.2 percent). The collaborative practice agreement increases P&T guideline adherence in adjusting for renal impairment; however, there is room for improvement. Education of pharmacy staff may be of value. The P&T Committee may reconsider the addition of obesity dosing to the collaborative practice agreement.

Submission Type: Evaluative Study

Session-Board Number: 2-122

Poster Title: Developing and piloting a model to improve geriatric chronic care management outcomes

Primary Author: Paria Kalantari, University of Kansas School of Pharmacy, Kansas; **Email:** pariabk@gmail.com

Additional Author (s):
Crystal Burkhardt
Brittany Melton
Deon Hayley

Purpose: About 5% of Medicare beneficiaries account for approximately half of Medicare expenditures. These high-cost beneficiaries tend to be older, disabled and more likely to have multiple chronic conditions, which have high symptom burden and functional impairment. The purpose of this study was to explore an alternate model of delivering chronic care management (CCM) to a geriatric population while assessing the impact on patient satisfaction, patient perceived health status, and use of hospital and emergency department services as compared to usual care.

Methods: A prospective cohort study was designed to evaluate a geriatric population enrolled in the care of an interprofessional chronic care management (IP-CCM) service. Three study arms were established to assess the study outcomes. The primary outcome was to reduce preventable hospitalization and emergency department (ED) service utilization. The secondary outcomes were to improve patient perception of care and self-assessed health status and to reduce use of potentially inappropriate medications. Intervention arms included patients who received the IP-CCM service and the clinic's standard CCM service. The control arm included patients who continued to receive usual care. Descriptive statistics were used to assess baseline characteristics of the study population to ensure similar groups were enrolled in each study arm. This study was approved by the IRB.

Results: A total of 448 patients were enrolled which included, 58 IP-CCM patients, 160 CCM patients, and 230 standard care patients at baseline. IP-CCM patients had an average age of 75.5 years, and were 86.2% Caucasian, 12.1% African American, and 1.7% other race. The

average CCI of the IP-CCM group was 5.65, with 29% diagnosed with dementia. The baseline possibly preventable rate for hospitalizations was 11 of 28 total hospitalizations, and for ED use was 15 of 28 total ED visits. CCM patients had an average age of 75.3 years, and were 68.8% Caucasian, 27.5% African American, and 3.8% other race. The average CCI of the IP-CCM group was 6.3, with 23% diagnosed with dementia. The baseline possibly preventable rate for hospitalizations was 26 of 53 total hospitalizations, and for ED use was 34 of 50 total visits. Standard care patients had an average age of 74.3 years, and were 74.4% Caucasian, 12.2% African American, and 10.4% other race. The average CCI of the Standard Care group was 5.5, with 21% diagnosed with dementia. The baseline possibly preventable rate for hospitalizations was 27 of 59 total hospitalizations, and for ED use was 37 of 62 total visits.

Conclusion: There were no significantly different trends noted between the study arms in this study. Lessons gained from this study will inform the best practices of how to administer Chronic Care Models in large academic ambulatory care settings.

Submission Type: Descriptive Report

Session-Board Number: 2-123

Poster Title: Value of Sequencing-guided Treatment in Breast Cancer Patients

Primary Author: Kelsie Fiss, University of Kansas School of Pharmacy, Kansas; **Email:** kmfiss@kc.rr.com

Additional Author (s):
Tessa Reynolds
Katelyn Zink
Brian Leyland-Jones
Casey Williams

Purpose: Breast cancer patients who have under gone molecular profiling and utilized sequence-guided treatment have lead to 55% of advanced breast cancer patients responding to either a complete response or partial response. Using sequence-guided therapy instead of just traditional chemotherapy is often reserved as last line use due to cost. The value of sequence-guided treatment is often overshadowed by the price so this study was designed to show the value in the added cost of the sequence-guided therapies.

Methods: This was a single center retrospective observational study including patients diagnosed with breast cancer between 1991 and 2016 at Avera Cancer Institute in Sioux Falls, South Dakota. All patients were sequenced after consultation with the genomic sequencing team at Avera Cancer Institute. Tissue for sequencing was obtained from the original diagnostic biopsy or re-biopsy of primary tumor. Sequencing treatments were based off designated targets determined from the FoundationOne and Garden360 or Theralink genomic analysis. A review of all patients past documents were used to collect all past and current cancer regimens including traditional therapy and sequence-guided therapy. Therapy costs were determined based on AWP pricing and a standard patient size of 180lbs and BSA 1.8m2

Results: Cancer treatment costs for thirty-six total patients were collected. Twelve patients were neoadjuvant, 12 patients were adjuvant, and 12 patients were metastatic. The primary outcome was cost of sequence-guided cancer treatment and response to cancer treatment. In all three categories, the sequence guided therapy made up the majority of the total cost for the patients' treatment. In metastatic patients the total cost tripled the total cost of neoadjuvant or

adjuvant patients. This is due to the one drug at a time, trial and error standard treatment carried out in metastatic disease. So by giving patients sequence guided treatment up front they can receive greater outcomes while also exposing the patient to a less toxic side effect profile. This can help improve the quality of life while on treatment and to better prevent metastatic disease where the total cost of treatment can triple the total cost seen in neoadjuvant or adjuvant disease.

Conclusion: Sequence guided therapy early in the neoadjuvant of adjuvant setting provided patients with an overall reduced cost of care throughout their therapy while delaying the progression of disease. If patients pay the up front cost of sequence guided treatment in neoadjuvant or adjuvant disease, there is a greater chance of complete or partial response. With an improved outcome compared to traditional therapies, we found there is value for paying for sequence-guided therapy early on in the neoadjuvant or adjuvant setting.

Poster Title: Complicated Pregnancy Due to Prolonged Fetal Exposure to an Angiotensin-Converting Enzyme Inhibitor

Primary Author: Monica Saha, University of Kansas School of Pharmacy, Kansas; **Email:** mds2008@ku.edu

Purpose: This case report details ACE inhibitor fetopathy. Baby boy T 's mother has a history of chronic hypertension reports using her mother in laws Lisinopril/HCTZ 20 mg/12.5 mg during pregnancy when her blood pressure was high. She reports stopping the medication 12 weeks into her pregnancy. Prenatal ultrasounds noting enlarged, echogenic kidneys. There was a 3-4 week period of anhydraminos, but the fluid level returned to normal prior to delivery. Prenatal ultrasound at 24 weeks noted anhydraminos when fluid has been previously noted on 20 week ultrasound. Infant was born via C-section due to complication of advanced maternal age, severe pre-eclampsia, placental insufficiency, and ductus elevations. Baby Boy T has large anterior and posterior fontanelle with significantly separated sutures. Small sutures with significant portion of the head unprotected with skull bones consistent with hypocalvaria. This warrants concern for ACE inhibitor fetopathy. Along with skull malformations, the infant has congenital anomaly of kidney. Subsequent basic metabolic panel shows a rise in anion gap, serum creatinine, and phosphorus, albumin, and potassium with peaked T wave. This is likely underlying chronic kidney disease. Impaired renal concentrating ability has also polyuria. Daily monitor of I/Os and hemodynamic status as well as replenishing fluids as needed. One dose of Lasix 2mg/kg PO was given and potassium began to trend down. Baby boy T's kidneys and brain will be carefully monitored throughout his first year of life. This case study suggests the harmful toxicity of taking medication prescribed for another individual without provider consent.

Poster Title: Pharmacy discharge medication counseling: An analysis of the impact on chronic obstructive pulmonary disease and asthma readmission rates in an academic, tertiary-level institution

Primary Author: Bethany Crotts, Sullivan University College of Pharmacy, Kentucky; **Email:** bcrotts18@gmail.com

Additional Author (s):
Logan Roberts
Ryan Vogt
Madeline Moses
Brette Conliffe

Purpose: Both chronic obstructive pulmonary disease (COPD) and asthma can cause frequent readmission to hospitals nationwide. Readmission can be directly linked to failure to properly adhere to a medication regimen and incorrect use of prescribed maintenance inhalers. Through a "Meds 2 Beds" program at an academic, tertiary-level institution, pharmacy-led discharge medication counseling integrated with medication delivery was implemented to provide patient education and follow-up in order to improve adherence and outcomes and decrease same-cause readmission. This study seeks to evaluate the impact of the Meds 2 Beds program on readmission rates for patients readmitted with either COPD or asthma exacerbations.

Methods: This study is a retrospective, observational chart review to evaluate if patients who were admitted for a COPD or asthma exacerbation between April 1, 2016 and August 1, 2016 and then participated in the Meds 2 Beds program had a decrease in same cause readmission. Patients who participated in the Meds 2 Beds program during this time period were compared to those patients who did not participate in the program. The primary outcome for this study was 30-day readmission for COPD or asthma exacerbations, as defined by ICD-10 codes. Secondary outcomes included 7-day readmission rate.

Results: For this time period, a total of 120 qualifying patients were admitted to the hospital with COPD or asthma exacerbations and, of these, 8 participated in the Meds 2 Beds program. Thirty-day readmission occurred in 15 of the patients who did not participate in the program

(13.3%) and only one (12.5%) occurred in the Meds 2 Beds participant group (p=01.0). Rates of 7-day readmission rates were non-significantly reduced (5 [4%] in non-participant group, 0 [0%] in participant group, p=1.0).

Conclusion: As this study shows, innovative pharmacy services such as a medication delivery and education service like the Meds 2 Beds program have the potential to decrease 30-day and 7-day readmission rates for chronic conditions like COPD and asthma, which would lead to increased positive patient outcomes while decreasing hospital costs. Further study is warranted with a larger study population to determine the exact effect of this type of program.

Poster Title: Innovative activities used to educate high school students on preventing the spread of sexually transmitted infections

Primary Author: Maria Masood, Sullivan University College of Pharmacy, Kentucky; **Email:** masoodmaria@yahoo.com

Additional Author (s):
Catherine Serratore
Megan Staples
Cathy Spencer
Stacy Miller

Purpose: Healthy People 2020 describes the need for further education on prevention of sexually transmitted infections (STIs), as well as promotion of STI screening in the adolescent population. Given this, Sullivan University College of Pharmacy started a new project titled Operation Protect Yourself, allowing student pharmacists to use innovative strategies to educate high school students about STI transmission and prevention. The purpose of this study was to assess the effectiveness of teaching methods used to deliver STI education to high school students. This project involved the use of an anonymous pre- and post-program quiz for high school students.

Methods: This multicenter observational study was approved by the Sullivan University Institutional Review Board. Subjects were high school students, ages 14 to 19, who were in attendance of the Operation Protect Yourself program. Operation Protect Yourself is a student pharmacist run program that goes to various high schools in the Louisville Metro area and teaches a 50-minute STI presentation to 6- 8 classes in one day. Along with a PowerPoint presentation, multiple active learning strategies (two games and a classroom discussion) are employed to help the students conceptualize the prevalence and transmission of STIs, the signs and symptoms of STIs, and preventative strategies. Students complete a pre-program quiz, which includes five knowledge-based questions. After the program, students complete a post-program quiz containing the same five knowledge-based questions, plus five additional questions assessing the students' perceptions of the program. The primary outcome of this study was students' confidence in their ability to protect themselves against STIs after the

presentation. To assess knowledge gained, a secondary outcome was change in score from pre-quiz to post-quiz for knowledge-based questions. Pre- and post-program quiz scores were analyzed and compared using a paired t-test, with students serving as their own control group. Other secondary outcomes included student perceptions of knowledge gained, likelihood of discussing STIs with their parents after the program, and students' preferred learning styles.

Results: A total of 1,663 students were educated on STIs and completed a survey; 137 of the surveys were excluded due to insufficient completion. Results from the primary outcome showed 91.9 percent of high school students felt confident in their ability to protect themselves from STIs after attending the programming. Students scored 25 percent higher on knowledge-based questions on the post-program quiz compared to the pre-program quiz (3.78 versus 3.02 out of 5.0 total; mean increase of 0.76, 95 percent CI 0.67-0.85, p less than 0.0001). Additionally, 88.6 percent of high school students felt the presentation improved their knowledge of STIs. Despite encouragement to discuss STIs with their parents from the presenters, only 31.7 percent of high school students said they were likely to discuss STIs with their parents after completing the program. When asked about their favorite part of the STI education program, 83.9 percent of students identified an active learning strategy.

Conclusion: This study found that the Operation Protect Yourself STI education program was effective at increasing confidence and knowledge regarding STI prevention among high school students. The program did not effectively motivate high school students to discuss STIs with their parents; therefore, other methods should be utilized in the future if aiming to increase STI discussion among students and parents. This cohort of high school students preferred to use active learning strategies to learn about STIs; therefore, other groups aiming to provide STI education to youth should consider incorporating active learning into their teaching.

Poster Title: Evaluation of crosstalk between clinical and pharmaceutical sciences departments

Primary Author: Emily Jones, Sullivan University College of Pharmacy, Kentucky; **Email:** ewimbe4347@my.sullivan.edu

Additional Author (s):
Kathryn Bandy
Cathy Spencer
Emily Esposito
Arthur Cox

Purpose: Currently, clinical and basic sciences are not integrated at Sullivan University College of Pharmacy. A method, referred to as "crosstalk" was implemented, with the goal of improving the consistency of information taught, as well as to improve application skills. Prior studies have evaluated integration of courses in a traditional four-year pharmacy curriculum; however, to our knowledge, no studies exist evaluating crosstalk in a three-year accelerated program. The purpose of this study was to evaluate student perceptions of lectures taught via the crosstalk method, as well as student performance on material taught via this method.

Methods: Lecturers for the therapeutics, pharmacology, and medicinal chemistry portions of Parkinson's Disease met prior to class and discussed the delivery and focus of the disease. During the "crosstalk" session, lecturers focused on four main points: 1) eliminating or reducing contradictions in material taught; 2) reducing redundancy; 3) applying active learning strategies to improve application of basic sciences to clinical sciences; and 4) standardizing the slides (i.e., cover the drug classes in the same order, choosing the same drugs to highlight from each class). The primary endpoint was change in student performance on assessments, before and after crosstalk implementation. Exam scores for the Class of 2016 (with crosstalk) were compared retrospectively to the Class of 2015 (without crosstalk), using a two-sample independent t-test with an online software program, OpenEpi. After the lectures, second-year students at Sullivan College of Pharmacy participated in a survey evaluating the effectiveness and clarity of Parkinson's disease lectures taught via the crosstalk method. Secondary objectives included student perceptions of consistency of information delivered, student understanding of the rationale for the information delivered, and student perceptions of active learning on their

ability to apply information learned. An anonymous survey was delivered through Survey Monkey and included nine questions, with the options based on a four-point Linkert-type scale. Descriptive statistics were used for the secondary endpoints.

Results: A total of 73 students in the Class of 2016 (with crosstalk) and 91 students in the Class of 2015 (without crosstalk) were compared for the primary endpoint. Students scored significantly higher when taught via the crosstalk method in medicinal chemistry (88.3% vs. 76%; $p < 0.001$) and pharmacology (86.8% vs. 78.6%; $p < 0.001$). There was not a significant difference in the therapeutics scores (82% vs. 85.3%; $p=0.116$). Of the 73 students taught via the crosstalk method, 43 completed the anonymous survey. The secondary outcomes, survey data, reported that 97.73% (n=43) thought that compared to other lectures, the Parkinson's Disease lecture had more consistency and fewer contradictions between therapeutics, medicinal chemistry, and pharmacology. Compared to other lectures, 97.73% also reported that they were better able to understand the rationale taught in each subject: pharmacology, medicinal chemistry, and therapeutics. All survey participants claimed that it was evident that the lecturers coordinated and intentionally sequenced their lecture materials for this lecture. In addition, 100% students reported that the active learning and patient case were helpful and effective.

Conclusion: The significant improvement in exam scores for medicinal chemistry and pharmacology suggest crosstalk method had a positive impact on student learning. The survey results indicated students perceived benefit from this teaching style, including improvement in their ability to apply the basic sciences into clinical practice. Future studies will focus on evaluating a larger cohort, as well as the impact of crosstalk on multiple disease states. The 2016 Accreditation Council for Pharmacy Education standards emphasize the need to integrate content and incorporate active learning into didactic courses; crosstalk is one potential method to assist in achieving this standard.

Submission Category: General Clinical Practice

Submission Type: Evaluative Study

Session-Board Number: 2-128

Poster Title: Perceived benefits and motivations of students who may enroll in a landmark trials elective course

Primary Author: Abby Taylor, Sullivan University College of Pharmacy, Kentucky; **Email:** ataylo5662@my.sullivan.edu

Additional Author (s):
Ashley Potts
Emily Frederick

Purpose: Landmark Trials is a course designed to reinforce current clinical evidence-based medicine and allow students to practice evaluating literature and creating and presenting clinical trial data and analyses. Preliminary data revealed that students who took the class may have performed better on a standardized exam; however, student motivation for electing this learning opportunity as well as perceived benefits remain unclear. This project was designed to determine student motivations and perceived benefits from taking the course, and if it or its components should potentially be incorporated into the core curriculum at a college of pharmacy.

Methods: A 10-item survey was designed to capture the reasoning behind why students did or did not take landmark trials and any reported benefits from taking the course. The survey included questions regarding why or why not the student chose to take the course, the extent he/she did or did not benefit from taking the course, and if he/she feels this course should be a requirement in the core curriculum. Sections were also available for further comment. The survey link was sent via email to students in the immediate past graduating class, the current graduating class, and the class currently enrolling in elective courses. This study was submitted to and approved by the University's Investigational Review Board.

Results: The survey received 75 responses. Of the 40 students that had already taken the class or were signed up to take it, 39 (97.5%) believed it helped them feel more confident while on rotations, and 40 (100%) believed they felt more prepared for journal clubs and literature evaluation. Of note, 10 of these 40 students (25%) took the course to improve necessary skills

for residency training. Out of all of the survey respondents, 47 (62.7%) either agreed or strongly agreed that the landmark trials elective should be a required course in the curriculum.

Conclusion: The landmark trials course was perceived to be of value to the students that took the elective. Based on previous data and positive student response, it may be beneficial for the college of pharmacy to incorporate this course or its most meaningful components into the required part of the curriculum and further disseminate its design and outcomes.

Poster Title: Advancing pedagogy in pharmacy for learning excellence.

Primary Author: David Eigsti, Sullivan University College of Pharmacy, Kentucky; **Email:** deigst3420@my.sullivan.edu

Additional Author (s):
Veraporn Jerus
Barbara Jolly
Amber Cann

Purpose: Sullivan University College of Pharmacy (SUCOP) is an intensive 3-year program, as such professors' time with students must be focused and effective. Literature currently suggests that there is a variance in the learning style preferences of pharmacy students. Furthermore, we may infer that students may not experience success with the more traditional teaching style of lectures. This study was designed to identify the variance, and implement new tools to improve student test scores.

Methods: Over a period of several years, the Health Professionals' Inventory of Learning Styles survey was administered to students during the pharmacy year 1 at the college. It became evident that every year the majority of students are "Assimilators," meaning they prefer to study alone, ask few questions in class, and learn best through observing others. Previous exams were evaluated for core concepts that students failed to master. Enhanced learning styles such as screencasts, videos, and self-paced learning tools were prepared and evaluated by two focus groups of 7-10 students who had completed courses from which these core concepts had come. With the guidance of the focus groups and with the understanding that the majority of students are Assimilators, new education methods were implemented, notably 3-5 minute instructional videos that can be accessed outside of the classroom. The Class of 2016 was then evaluated based on the same core concepts in which previous classes had struggled. In the following years, SUCOP has continued to administer the H-PILS survey.

Results: H-PILS survey classifies students as Accommodators (prefers group work), Assimilators (studies alone and asks few questions), Convergers (leadership qualities), or Divergers (resourceful and tries to impress others). In the Class of 2015: 57.7 percent of students were Assimilators, 20.2 percent Convergers, 5.8 percent Accommodators, and 3.8 percent Divergers. Class of 2016: 65 percent Assimilators, 15 percent Convergers, 5 percent Accommodators, and 4 percent Divergers. Class of 2017: 61.5 percent Assimilators, 17.9 percent Convergers, 5.1 percent Divergers. Class of 2018: 51 percent Assimilators, 21 percent Convergers, 5 percent Accommodators, and 3 percent Divergers.

Core concepts evaluated in the class of 2014 and class of 2015 included the dilution of sterile powder calculation, drip rate calculations, basal energy expenditure calculation, and body surface area calculation. The average percentage of students to answer questions in each of these categories correctly was 84.8. The class of 2015 had a fifth category added for calculation of osmolarity with only 57.8 percent of students correctly answering that question. After the addition of the enhanced learning tools, the Class of 2016 answered the first four core concepts with an average of 98.5 percent correct, and the fifth category with 84.0 percent.

Conclusion: Pharmacy students have a predictable learning style profile that does not fit the traditional lecture format. The University of Louisiana Monroe has also begun administering the H-PILS survey and have found strikingly similar results. They have agreed to a joint continuation of this study. With rapid changes happening to the world of pharmacy, including those to the North American Licensure Examination, it is no longer feasible to expect students to be able to learn solely through standard lecturing, and hope to see improvements. We suggest learning tools and lectures be formatted or altered to better cater to students' needs.

Poster Title: Integrase inhibitor verus Protease inhibitor-based Therapy for treatment of HIV-1 infection in patients presenting with Acquired Immunodeficiency Syndrome

Primary Author: Lucy Nguyen, SULLIVAN UNIVERSITY COLLEGE OF PHARMACY, KENTUCKY;
Email: lnguyen1080@gmail.com

Additional Author (s):
TARA YEGANEH
CATHERINE SPENCER
DANIEL TRUELOVE
MARY BISHOP

Purpose: Acquired Immunodeficiency Syndrome is a complication resulting from the human immunodeficiency virus (HIV) that attacks the body CD4 cells. The preferred antiretroviral regimens (ART) are 2 non-nucleotide reverse transcriptase inhibitors (NNRTI) in combination with a third active drug such as a protease inhibitor (PI) or an integrase inhibitor (INSTI). Most studies comparing INSTI and PIs have either excluded patients with low CD4 counts (< 200) or have limited patients included. The purpose of this study is to investigate the efficacy between PI-based and INSTI-based regimens in patients presenting to clinic with CD4 ≤ 200 cells/mm3, with or without an opportunistic infection.

Methods: In this retrospective, non-inferiority, matched-cohort study, patients with HIV were selected via the Careware® database from a Ryan-White funded HIV clinic. The inclusion criteria included males and females≥18 years old who were treatment naïve with CD4 counts ≤ 200 cells/mm3 or ≤ 14%. The exclusion criteria included pregnant women, age < 18 years, CD4 count ≤ 200 cells/mm3 with or without opportunistic infections. The selected patients were then screened and divided in a 1:1 ratio into 2 groups: PI-based regimen and INSTI- based regimen. Groups were matched based on sex and age. Within these two groups, the patients were then stratified based on presence of opportunistic infection and baseline viral load (< 100,000 copies/mL vs. >100,000 copies/mL). Data points were collected to determine effectiveness among this patient population of PI-based regimens vs. INSTI-based regimens on ability to reach viral suppression.

Results: The primary outcome of the study was the proportion of patients that reached viral load suppression (defined as RNA viral load of < 50 copies/mL). We screened a total of 134 patients and 88 patients met the inclusion criteria. The results showed that there is no significant difference between the PI-based regimen vs INST-based regimen in viral load suppression; the p value was greater than 0.05, 95% CI (0.73 – 2.55).

Conclusion: There is no significant difference between the PI-based regimen vs. INST-based regimen in viral load suppression. Additional outcomes will be presented at the Midyear.

Poster Title: Analyze Drug Enforcement Administration 106 Report of Theft or Loss of Controlled Substance

Primary Author: Zarreen Ahmad, Sullivan University College of Pharmacy, Kentucky; **Email:** zahmad3910@my.sullivan.edu

Purpose: In order to decrease the amount of thefts and loss of controlled substances in Kentucky, we need to identify risk factors for pharmacies. Information in the Drug Enforcement Administration (DEA) 106 forms can be used to identify trends and patterns in the theft and loss of controlled substances. This information will help pharmacists in Kentucky take precaution to prevent theft and loss of controlled substance. Phase I of the study will focus on identifying the amount of DEA 106 forms submitted to Kentucky Board of Pharmacy based upon pharmacy setting and identifying the number of thefts involved in Hospital/Clinical Setting.

Methods: The study design is a retrospective study and will be analyzing data from the DEA 106 reports between the years of 2014-2016. The DEA 106 report is sent directly to the Kentucky Board of Pharmacy. The study population will include pharmacies.

Results: According to 304 DEA 106 forms submitted to the Kentucky Board of Pharmacy between the years 2014-2016, we found pharmacies identified as "Retail" settings submitted 267 DEA 106 forms, pharmacies identified as "Hospital/Clinic" submitted 27 DEA 106 forms and pharmacies identified as "Distributors" or "Mail Order Pharmacy" submitted 10 DEA 106 forms. Hospitals/Clinics DEA 106 forms were further analyzed and found "Employee Pilferage" was mentioned in 17 out of 27 forms.

Conclusion: In conclusion, the DEA 106 reports contain a lot of beneficial information that can be used to identify trends and patterns on the theft and loss of controlled substances, which can help pharmacies take precaution and prevention as needed. This study is an ongoing study and will be further investigating and identifying trends and patterns of theft and loss of controlled substances utilizing the DEA 106 reports.

Poster Title: Impact of Home SSRI/SNRI Continuation on Sedation Outcomes in Medical Intensive Care Unit Patients

Primary Author: Jenee Gisewhite, UKHealthCare Good Samaritan Hospital, Kentucky; **Email:** jenee.cousineau@uky.edu

Purpose: Limited clinical data exists regarding the impact of restarting home neuropsychiatric medications and sedation-related outcomes in the ICU. The purpose of this study was to compare sedation-related outcomes between patients restarted on their home SSRI/SNRI in the first 5 days of their ICU stay versus those who were not.

Methods: The institutional review board approved this single center retrospective chart review. Adult patients admitted to the medical ICU (MICU) at University of Kentucky Chandler Hospital between January 2011 and January 2015 taking an SSRI or SNRI prior to admission were included. Patients had to be intubated prior to or on admission to the MICU and must have received benzodiazepine based sedation from admission to >/= 5 days. Those admitted to the MICU for overdose, who were extubated in < 72 hours within admission, or were receiving high-dose benzodiazepines for deep sedation were excluded . Patient The primary objective was to compare the median daily RASS scores observed in each cohort. Secondary objectives included the average total daily dose of benzodiazepine sedation during the first 5 days of the ICU stay between the cohorts, rates of new-start anti-psychotics as a surrogate outcome for delirium, and lengths of stay and ventilator days between cohorts.

Results: A total of 67 patients were included in the study on a home medication regimen consisting of one or more antidepressant medications associated with serotonin reuptake such as the SSRIs or SNRIs. The baseline age, Charlson Comorbidity score, UHC predictor of mortality, and midazolam requirements during the first 2 days were comparable in both sets of patients. More patients who had their home SSRI/SNRI restarted within 5 days (early restart group) had median RASS scores within goal range , compared with those who had their home SSRI/SNRI started back after 5 days or not at all (late restart group) (73% vs. 46% respectively; p=0.04). Median RASS scores were lower in the early restart group (1.5 (-2.0 to -1.0)) compared to those in the late restart group (-2 (-3 to -1.5), p = 0.01). There were no differences between early and late restart cohorts in cumulative benzodiazepine dose received (median 297.5 mg vs. 213.5

mg, p = 0.27), ventilator days (median 7 days vs. 8 days, p = 0.65), or rates of new- start antipsychotics (30% vs. 11%, p = 0.49).

Conclusion: Re-starting home SSRI/SNRIs within 5 days of ICU admission was associated with patient's maintenance of lighter levels of sedation within the goal RASS range while intubated in the MICU. While restarting these medicines may facilitate light sedation, they were not associated with a reduction in cumulative BZD dosing, mechanical ventilator days, or surrogate markers for delirium.

Poster Title: Characterization of opioid overdose at an academic medical center

Primary Author: Jessica Bugg, University of Kentucky, Kentucky; **Email:** jessi.bugg@uky.edu

Additional Author (s):
Kate Morizio
Abby Bailey
Regan Baum
Julia Martin

Purpose: Prescription opioid abuse has been a pervasive problem in the United States. In Kentucky, laws have been passed to decrease access to prescription opioids. As a by-product, rates of heroin abuse have increased. As heroin and prescription opioids very in their pharmacokinetics and routes of administration, they may require different treatment modalities. Most information related to overdose comes from monitoring systems, not medical centers, where treatment occurs. The goals of this study are to describe heroin and non-heroin overdoses at an academic medical center and the dosing schemes of naloxone used to treat overdose events.

Methods: 926 patients presenting to the emergency department with a diagnosis of opioid overdose were retrospectively reviewed between January 1, 2005 and September 15, 2015. Patients were excluded if the overdose was due to non-opioids or an unknown substance, if pregnant, or if transferred from an outside hospital. The primary objective was to characterize patients who present with heroin and non-heroin overdoses and identify differences in demographics and past medical history between the groups. Secondary objectives were to determine whether there was any significant difference in the management of these patients, especially with respect to naloxone use. Data collected included patient demographic information, chief complaint upon admission, pertinent past medical history and social history, pertinent home medications, date and time of presentation to the institution, mode of arrival, length of stay in the ED, intensive care unit, and overall hospital length of stay, days of mechanical ventilation, and in-house and 28-day mortality. Data collected related to the use of naloxone included: whether the patient required naloxone administration en route or upon

arrival, whether continuous infusion or bolus naloxone administration was used, and cumulative dose of naloxone required.

Results: 482 patients were included in the non-heroin group, and 444 patients were included in the heroin group. Over the study period, the number of heroin overdoses seen per year steadily increased as non-heroin overdoses steadily decreased over the study period. The heroin group contained more patients who were younger by comparison to the non-heroin overdose group. In addition more patients had a diagnoses of hepatitis C. Patients in the heroin group were also more likely to have had a previous overdose event (p=0.007), history of injection drug use (p= < 0.0001), and prescription opioid abuse (p= < 0.0001). The non-heroin group contained more patients with a history of benzodiazepine abuse (p= < 0.0001). Treatment also varied between heroin and non-heroin groups, with the heroin group being more likely to receive naloxone en-route to the hospital (p= < 0.0001), but less likely to receive it upon admission (p=0.0017). The non-heroin group was more likely to receive significantly more total naloxone (p=0.05), as well as need a continuous infusion and were more likely to be admitted (p=0.04). While the cost of admission was also significantly higher in the non-heroin group (p= 0.0001), in-house and 28 day mortality was not significantly different between groups (p=0.98, p=0.44 respectively).

Conclusion: This data supports prior findings which indicate there are an increasing number of overdose patients presenting to emergency departments. A notable difference between groups was that non-heroin overdoses required more naloxone compared to heroin overdoses. The longer half-life of prescriptions opioids likely results in longer hospital stays and higher naloxone requirements. This may also be the cause of higher costs of admission shown with the non-heroin group. More studies are needed to determine if different protocols need to be used in heroin and non-heroin opioid overdoses, and more resources are needed in order to curb addiction and overdose events.

Submission Type: Evaluative Study

Session-Board Number: 2-134

Poster Title: Characteristics of asthma patients using high volumes of inhaled short-acting beta-agonists (SABA) in Scotland

Primary Author: Anna Albert, University of Kentucky, Kentucky; **Email:** anna.albert@uky.edu

Additional Author (s):
Stuart McTaggart
Barry Melia

Purpose: Asthma is a disease that results from inflammation and constriction of the airways leading to symptoms such as wheezing, cough, shortness of breath, and chest tightness. Short acting beta agonists (SABA) are used to relieve symptoms associated with an acute asthma attack. It has been previously identified that patients who use large amounts of SABA inhalers are more likely to be poorly managed. The objective of this study was to determine if there are specific patient characteristics that could predict if a patient was more likely to excessively use SABA inhalers and therefore, have poorly managed asthma.

Methods: All people aged 0-44 years in Scotland (population 5.3 million) who received at least one SABA inhaler between January through December 2015 were identified from the national prescribing information system (PIS). PIS does not hold diagnosis information so an upper bound of 44 years was used to restrict subjects to those with asthma and not chronic obstructive pulmonary disease (COPD). The number of inhalers received was recorded as was gender, five-year age band and Scottish index of multiple deprivation (SIMD) decile. SIMD incorporates several aspects of deprivation into a single measure that is applied to neighborhoods that can then be ranked. Patients who received greater than 12 inhalers were identified and between group comparisons were evaluated using the z-test. Relationships with age and SIMD were investigated using linear regression.

Results: Of 250,304 people treated with a SABA during 2015, 19,584 (7.6%) received greater than 12 inhalers. Of these patients, 10,634 (54.3%) were male and males were the majority in each age group. This difference became most apparent and widened from adolescence. There was a strong correlation between using >12 SABA inhalers and increasing age (R^2=0.93, p-value < 0.0001). In addition, there was a strong association with increasing levels of deprivation and

the proportion of patients to using >12 SABA inhalers. (R2=0.99, p-value < 0.0001). Of the population that used >12 SABA inhalers, 11% of patients were in the most deprived group versus 5% of patients were in the least deprived group (p-value < 0.05).

Conclusion: In patients aged 0-44 years, using >12 SABA inhalers in 12 months was associated with increasing age, being male and living in a socio-economically deprived area. It is hard to say why these patients are more likely to use SABAs excessively. A variety of factors may be involved including: accessibility to healthcare lack of engagement with such services, or an education gap on proper inhaler use. By being aware of the populations most at risk, pharmacists will be able to begin to intervene in the asthma management of these patients—decreasing exacerbations, increasing quality of life, and decreasing healthcare costs.

Submission Type: Evaluative Study

Session-Board Number: 2-135

Poster Title: Influence of age, gender, and deprivation on the prescribing of gabapentinoids in Scotland

Primary Author: Lyndi Laney, University of Kentucky, Kentucky; **Email:** lyndi.laney@uky.edu

Additional Author (s):
Stuart McTaggart

Purpose: Chronic pain management presents a major therapeutic, emotional, and financial challenge to both patients and clinicians. Nearly one in every five patients in Scotland is affected by chronic pain. With the increase in opioid prescribing during the last 20 years, numerous epidemiological studies have reported that higher deprivation has been correlated with higher use of opioid agents.
The prescribing of pregabalin and gabapentin has also increased due to their utility in addressing chronic pain. Our aim was to utilize national prescribing data in order to investigate if deprivation, age, or gender influences the prescribing of pregabalin and gabapentin.

Methods: The national prescribing information system (PIS) holds information on all National Health Service (NHS) prescriptions dispensed within community pharmacies in Scotland (population 5.3 million). Each patient is assigned a unique patient identifier (CHI number), which grants access to demographic information and allows for the events relating to an individual to be linked together. Using PIS, all patients that had received a prescription for an analgesic in 2014 or 2015 were identified. Patients were then stratified by age, gender, Scottish Index of Multiple Deprivation (SIMD) decile, and type of analgesic received: non-opioid, weak opioid (tramadol, codeine), strong opioids, or gabapentinoids (pregabalin and gabapentin). Using this data the number of patients treated with each type of analgesic was trended and compared between each of the 14 regional health boards throughout Scotland. Use of each type of analgesic was also compared between age bands, gender, and SIMD decile for the whole of Scotland.

Results: In 2014 1,459,440 patients were identified as receiving any type of analgesic prescription of whom 764,233 (52.3%) received non-opioids, 894,559 (61.3%) received weak opioids, 79,903 received strong opioids (5.4%), and 144,607 (9.9%) received gabapentinoids. In

2015 there was an overall increase of 19,236 patients receiving any analgesic (total of 1,478,376). There was also an increase in non-opioids (776,464-52.5%), strong opioids (86,516/-5.8%), and gabapentioids (160,801-10.8%). However, in 2015 there was a decrease in the amount of patients receiving weak opioid prescriptions with 890,413 (60.2%).

There was a strong correlation for increased use of all analgesic agents with increasing levels of deprivation (R^2=0.985; $p < 0.001$). There was also a strong correlation for gabapentinoid usage with increasing levels of deprivation (R^2=0.992; $p< 0.001$).

Overall there was greater analgesic use in females compared to males and greater use of gabapentioids in females with 134,293 patients compared to males with 84,097 patients (61.5% and 38.5% respectively). There was greater use of gabapentinoids in females compared to males in every age band, with the mean age of use being 53 years old for all patients. A difference in use between genders was greatest with the older age bands of 75-84 and 85 and up.

Conclusion: A significant proportion of the Scottish population received an analgesic agent in 2014 and 2015. The prescribing of these agents continues to increase, although the proportion of analgesic type is shifting toward gabapentinoid usage. There is a very strong correlation between deprivation and analgesic use, including gabapentinoids. In general analgesic use increased with aging and females had higher use compared to males in all age bands. The higher prescribing of gabapentinoids in elderly females may be due to greater longevity in females, differences in pain tolerance or due to indications other than chronic pain management.

Submission Type: Evaluative Study

Session-Board Number: 2-136

Poster Title: Assessment of the current reporting requirements of the Kentucky immunization registry

Primary Author: Lindsey Lewis, University of Kentucky College of Pharmacy, Kentucky; **Email:** lnle223@uky.edu

Purpose: Immunization registries were created to allow for data collection of patient-specific administered vaccines. This confidential reporting system was developed to improve population health by providing insight into vaccine compliance, disease prevention, and missed opportunities. While some regulations surround individual state registries, most states have optional reporting for the majority of healthcare providers. The purpose of the survey is to assess pharmacists' views of the Kentucky immunization registry. Survey focus is based around the satisfaction with current reporting requirements and the potential need to make reporting mandatory for all vaccines administered in the state of Kentucky.

Methods: In order to assess the need of expanding the current reporting requirements of the Kentucky immunization registry (KIR), a needs assessment survey was conducted. An Institutional Review Board (IRB) certified survey was administered to 1,000 randomly selected pharmacists registered within the state of Kentucky. The survey consisted of ten topic related questions and three demographic questions. The survey was available for a period of two months through the Research Electronic Data Capture (REDCap). REDCap is a secure, web-based application designed exclusively to support data capture for research studies. Once the link to the survey in REDCap was opened, the respondent would see a cover letter containing the applicable elements of informed consent. This cover letter explained the purpose of the survey. After reading the cover letter, the survey recipient would receive a unique pin-number that would allow them to log into the REDCap system to enter their survey responses. All data received from respondents completing the survey online was anonymous. Upon survey closure, results were analyzed through Microsoft Office Excel and Statistical Package for the Social Science (SPSS) to examine awareness of the KIR and current satisfaction with reporting requirements and to examine the importance pharmacists placed on missed opportunities and preventable disease prevention within the state of Kentucky.

Results: Out of the 1,000 pharmacists randomly selected to take the survey, 142 pharmacists completed the survey. In order to aggregate the collected data, all responses were averaged over a five point Likert scale. If the mean was less than the neutral value, three, then on average the surveyed group "agreed" with the statement. Comparatively, if the mean was greater than three, then on average the surveyed group "disagreed" with the statement. The further the mean is from the neutral value, the stronger the group felt about a particular question. P-values were calculated for each question to assess whether the responses to the questions were relevant and not based on chance. All questions were determined to have significance based on all p-values being reported as less than 0.05. Nine out of the ten questions reflected a mean of equal to or less than three. One question reflected a mean value greater than three, demonstrating unfamiliarity with the immunization registry. A Levene's test for equality of variances was conducted to compare how community pharmacists responded to questions in comparison to all other categories of pharmacy referenced within the survey. In two instances community pharmacists responses varied significantly from all others.

Conclusion: Immunization registries are becoming more prevalent in today's healthcare community. The ideology behind the purpose of the immunization registry seems clear among pharmacists in Kentucky, but the need for expanded reporting requirements is not as evident. While pharmacists view missed opportunities and preventable diseases as issues that Kentucky faces, they do not seem to be entirely convinced mandatory reporting to the immunization registry is the most efficient way to handle these issues.

Poster Title: Elucidating the pathway of mycobacterial cholesterol catabolism, a potential novel target for the discovery of tuberculosis therapeutics

Primary Author: Tyler Bucci, University of Kentucky College of Pharmacy, Kentucky; **Email:** tyler.bucci@uky.edu

Additional Author (s):
Steven Van Lanen

Purpose: Tuberculosis (TB), caused primarily by Mycobacterium tuberculosis (Mtb), remains one of the deadliest communicable diseases and is notorious for its cumbersome treatment regimen. A third of the world's population is estimated to be infected by the pathogen in the latent form, and efficient treatment against TB in the latent state has not yet been developed. The long-term goal is to develop novel therapeutics effective against latent TB including both drug-sensitive and drug-resistant TB. We hypothesize that cholesterol metabolism (specifically the oxidative degradation of the aliphatic side chain of cholesterol) is an ideal target for eradicating latent TB.

Methods: The majority of the genes essential for Mtb cholesterol metabolism have yet to be identified or functionally assigned. However, two proteins (FadD17 and FadD19) are well characterized in the literature to be involved in the cholesterol catabolism pathway of Mtb H37Rv. The genes encoding FadD17 and FadD19 are located in two separate genomic islands within the chromosomal DNA of Mtb H37Rv, and we and others have hypothesized that genes adjacent to fadD17 and fadD19 are also required for the cholesterol catabolism pathway. These two genetic loci were bioinformatically analyzed using the Department of Energy Joint Genome Institute Integrated Microbial Genomes and Microbiome Samples to identify 12 additional gene products that are potentially involved in this pathway. Each of these twelve genes as well as fadD17 and fadD19 was cloned and expressed in Escherichia coli BL21(DE3). The function of the soluble, recombinant proteins was tested in vitro using the expected substrate generated in situ using FadD17 or FadD19, which are both carboxylate-CoA ligases that 'activate' the aliphatic side chain of cholesterol to initiate the degradative pathway. Reactions were monitored by HPLC using diode array and charged aerosol detectors.

Results: After analysis of the two gene clusters that are putatively involved in cholesterol catabolism, we hypothesized that at least fourteen total genes were involved in the oxidation pathway. Only four of these genes (fadD17, fadD19, rvbd3504, and rvbd3505) have been characterized and are known to be involved in the cholesterol pathway. Eleven out of fourteen genes, which includes the four genes previously identified, were successfully cloned and expressed in Escherichia coli BL21(DE3) to yield soluble protein. The activity of FadD17 was confirmed as an ATP-dependent cholate:CoA ligases, which was aided by the use of synthetically prepared product as a standard.

Conclusion: Mtb is able to survive within harsh environments of our body by utilizing cholesterol from the cell membranes of our immune cells. Cholesterol is oxidized to provide a source of both carbon and energy to maintain metabolic functions of Mtb while residing in macrophages. Proposed genes involved in the oxidation pathway have been successfully identified and cloned. The results afford the opportunity to functionally assign and characterize the function of each gene product and ultimately developing high throughput activity-based assays to screen for potential inhibitors. These inhibitors could then be used as new medications to treat patients with TB.

Submission Category: Geriatrics

Submission Type: Evaluative Study

Session-Board Number: 2-138

Poster Title: Pharmacovigilance of statin therapy in adults over 75 years old in a geriatric and family medicine primary care clinic

Primary Author: Catherine Ammerman, University of Kentucky College of Pharmacy, Kentucky; **Email:** caam223@uky.edu

Additional Author (s):
Holly Oatman
Demetra Antimisiaris

Purpose: Statins have been proven effective in decreasing the risk of atherosclerotic cardiovascular disease. However, the use of statin therapy in those over the age of 75 years old is controversial due to changes in the aging process, an underrepresentation in clinical trials, and unclear recommendations in the American College of Cardiology and American Heart Association guidelines. The purpose of this study was to evaluate appropriate monitoring and documentation of statin therapy in adults over the age of 75 years old, as the safety and effectiveness of statin therapy is unclear in this population.

Methods: The institutional review board approved this observational, retrospective study. Data was obtained from Allscripts TouchWorks, an electronic health record system used by the University of Louisville Physicians group.
Men and women age greater than 75 years were included in this study if they were enrolled as patients in the University of Louisville Geriatric or Family Medicine clinics and were currently taking a statin at the time of initiation of the study. Statin therapy included atorvastatin, fluvastatin, lovastatin, pitavastatin, pravastatin, rosuvastatin, simvastatin, and simvastatin/ezetimibe. Patients who had not been seen in either clinic in the last 12 months were excluded from the study.
The data collected included the patient's medical record number, sex, age, race, body mass index, ideal body weight, serum creatinine, creatinine clearance, liver enzymes, total number of current medications, diagnosis of diabetes, diagnosis of hypertension, and presence or absence of liver or chronic kidney disease. All data was de-identified of patient specific information. The indication for statin therapy, statin dose and intensity, lipid panel results, reported adverse effects of statin therapy, and any notes from the provider regarding statin therapy were also

recorded. The data was analyzed using descriptive statistics to determine rates of appropriate statin therapy monitoring documentation in the study population.

Results: There were 222 patients found to be on statin therapy, with 60 percent on a statin for primary prevention. Regarding the statins prescribed, 15.8 percent of the patients were on a high-intensity statin and 50 percent were on a lipophilic statin. During clinic visits, 6.3 percent of patients discussed switching to a less lipophilic statin with their provider and 4.5 percent of patients discussed discontinuation of their statin completely. Providers documented the presence of absence of muscle pain, weakness, spasm, or cramps in 15.3 percent of the patients with 9 percent of the total patients specifically complaining of muscle symptoms. A creatine kinase test was performed in 6.3 percent of patients, but was only done in 1 of the 20 patients who complained of muscle symptoms. A lipid panel was absent in 27.6 percent of patients and 16.7 percent of patients did not have a new lipid panel completed in the past 12 months. There were 23.4 percent of patients who had a documented diagnosis of chronic kidney disease or renal insufficiency and 13.8 percent of these patients were on potentially inappropriate statin doses due to their declining renal function.

Conclusion: In this study of adults over the age of 75, it was found that the safety and appropriateness of statin therapy was not properly monitored and documented. The guidelines acknowledge that there are study gaps and future research needs regarding statin use for primary prevention of cardiovascular disease in older adults, thus highlighting the importance of pharmacovigilance in this population. Over half of the patients were prescribed a statin for primary prevention, with many lacking assessment of current lipid levels and adverse effects. This study exemplifies the need for providers to become more diligent in medication management in older adults.

Poster Title: Assessment of pharmacy professional year four advanced pharmacy practice experience (APPE) mock interview exercise

Primary Author: Raeschell Williams, University of Kentucky College of Pharmacy, Kentucky; **Email:** shelly.williams@uky.edu

Additional Author (s):
Anne Policastri

Purpose: During the Advanced Pharmacy Practice Experience (APPE) pharmacy students are given the opportunity to practice in various practice sites. In recent years, University of Kentucky College of Pharmacy faculty and administrators received anecdotal reports that students could benefit from practice interviews. Two mock job/residency/fellowship interviews have been incorporated into the APPE year to help the students hone their interview skills and increase comfort and confidence in the interview process. This study aims to examine student self-reported interview performance to determine if students improve between the first and second interviews.

Methods: To improve the students' performance during interviews, pharmacy faculty developed questions that evolved into a mock interview to be performed twice during the fourth professional year. Depending on the practice site, the interview is hosted by pharmacists, pharmacy residents, and other pharmacy staff to offer the student valuable feedback on their interview skills. Before each interview, the student completes the Pre-practice Interview Self-Assessment which gives a baseline assessment of the student's confidence in various interview areas. After each interview, the student completes the Post-Interview Self-Assessment and Reflection. This form offers the student the ability to comment on their interview performance as well as assess their confidence in how they performed in certain areas. The Post-Interview Self-Assessment and Reflection form consists of Likert-type response options as well as open-ended questions to assess students' perceptions of their performance on the interview, the most challenging interview questions, what made the interview successful, and ways to improve for future interviews. In order to interpret the open-ended response questions, thematic analysis was performed. Themes were extracted from the students' responses to the open-ended questions, which allowed the researchers to obtain an

overall sense for areas of weakness and places for development based on the extrapolated themes.

Results: Two-hundred thirty-four students completed the interviews – one hundred twenty- six in the Class of 2015 and one hundred eight in the Class of 2016. Five themes were extracted from the student responses in areas of improvement – Preparation, Recall, Nervous Habits, Confidence, and Other. Overall, the top three categories in which the majority of students in both class years self-reported needing to improve were preparation, confidence, and nervous habits. These themes were apparent both after Interview One and Interview Two. In terms of Likert-based response options, students improved overall from Interview One to Interview Two.

Conclusion: Mock interviews during the APPE year were beneficial in addressing student self-reported areas of weakness and places for improvement. The information gleaned from these interviews may be useful to college of pharmacy administrators, professors, and curriculum developers. The mock interviews can better prepare fourth-year pharmacy students for interview experiences they may encounter in their fourth year, as well as exposing other pharmacy students to real-life job interview experiences.

Poster Title: Effect of peer instruction on student retention in a pharmacotherapy course

Primary Author: Claire Hafner, University of Kentucky College of Pharmacy, Kentucky; **Email:** claire.hafner@uky.edu

Additional Author (s):
Craig Martin
Jeff Cain
David Feola

Purpose: Active learning has been studied in a variety of disciplines, including pharmacy coursework. It has been shown to improve learning and increase student understanding, as well as improve retention when compared to traditional lecturing.
Peer instruction, a specific method of active learning, consists of preparatory student reading assignments, followed by short in-class lectures and small-group student discussion. This process encourages students to think through the concepts of the subject and encourages collaboration and debate with classmates.
We hypothesized that peer instruction would improve student understanding and retention of two therapeutics topics taught to third year Doctor of Pharmacy students.

Methods: Peer instruction was implemented for two topics, Pharyngitis and Febrile Neutropenia, in a third year pharmacy therapeutics course. Students were assigned pre-class readings to complete, and a pre-lecture quiz was given at the beginning of class to assess student preparation and understanding. Class was conducted either traditionally or using peer instruction methods. In 2010 (N=124), Pharyngitis was taught using peer instruction, and Febrile Neutropenia was taught using traditional lectures. In 2012 (N=126), teaching methods were reversed. Post-lecture quizzes, given 60-90 days after class, were used to measure students' retention of the material, and differences between pre- and post-lecture quiz scores were analyzed between teaching methods for both topics. An exam was given to the students at the end of the block, and exam data pertinent to Pharyngitis and Febrile Neutropenia was gathered and analyzed as well.

Results: Mean pre- and post-lecture scores were collected for both Pharyngitis and Febrile Neutropenia. When peer instruction was implemented, post-lecture quiz scores averaged 14.5% higher than pre-lecture scores, although scores increased by varying degrees in the two topics. Conversely, post-lecture scores were 2.8% lower than pre-lecture scores with a traditional teaching method. Neither of these values reached statistical significance.
In addition to quiz scores, Pharyngitis and Febrile Neutropenia exam data was also evaluated. Exam scores were reported by topic as well as teaching method, and peer instruction vs. traditional lecture exam scores were averaged for each topic. On average, 77.61% of students answered the Febrile Neutropenia questions correctly. Comparatively, 68.76% of students answered Pharyngitis exam questions correctly. Similar to quiz score data, these values were not statistically significant.

Conclusion: Even though this study did not find a significant difference in student retention in peer instruction versus traditional teaching groups, further study should be done in larger settings to determine if a difference actually exists.

Poster Title: Developing a unique advanced pharmacy practice experience: Research in clinical practice

Primary Author: Peter Moran, University of Kentucky College of Pharmacy, Kentucky; **Email:** peter.moran@uky.edu

Additional Author (s):
Brittany Bissell
Emily McCleary
Alexander Flannery

Purpose: The American Society of Health-System Pharmacists (ASHP) requires accredited residency programs to incorporate research projects into training. Postgraduate year 1 (PGY1) pharmacy residents often lack expertise in clinical research and often are inexperienced with designing studies, implementing study protocols, and publishing relevant findings. The objective of this rotational experience was to develop an early introduction to the clinical research process to better prepare students for residency training and future research endeavors.

Methods: This Advanced Pharmacy Practice Experience (APPE) was student-initiated and designed to provide early exposure to the clinical research process that would be beneficial for a future clinical pharmacy practitioner. The six-week rotation allowed the student to undergo a self-directed learning process through clinical project management and shadowing experiences. The student's goals were drawn upon to tailor the experience toward the student's future career interests. Twice to thrice weekly topic discussions were planned surrounding core research topics, including developing research questions, ethics, statistics, and various advantages and disadvantages of study designs and analyses. The student was also required to attend lecture series on research topics offered by the Center for Clinical and Translational Science. Shadowing experiences were created with the university's investigational drug service, nurse research project coordinators, and multiple institutional review board meetings. Opportunities were arranged for the student to participate in a variety of study designs, including randomized clinical trials, prospective observational studies, and retrospective cohort

studies. The student participated in various projects across the continuum, from idea generation and protocol development to execution and analysis.

Results: This clinical research rotation enabled the student to gain first-hand exposure to a broad array of clinical research areas beneficial to future clinical pharmacy practice. Shadowing a variety of practitioners allowed the student to learn the practitioner's particular role and involvement in the research process. Reflections of these experiences were documented and discussed with the preceptor. The student and preceptor met daily to discuss status of projects on which the student was working. This experience also introduced the student to the challenges of project and time management with regard to the planning, execution, and manuscript writing for multiple projects occurring simultaneously. The student assisted in screening and enrolling efforts for a prospective double-blinded randomized control trial, screening and collecting data for a prospective observational study, as well as working on a retrospective cohort study and protocol writing to gain exposure to the early processes of designing clinical research. At the conclusion of this APPE, the student gained exposure to all aspects of research, from investigator-initiated projects to industry-sponsored studies and the role that the clinical pharmacist can play in each of these.

Conclusion: A clinical research APPE rotation is a novel way to prepare future graduates with a baseline level of research knowledge that prepares them to engage in clinical research as a resident and beyond.

Poster Title: Patterns of pharmacologic diabetic treatment in Scotland in the fiscal year 2015/2016

Primary Author: Rachel Priddy, University of Kentucky College of Pharmacy, Kentucky; **Email:** rachel.priddy@uky.edu

Additional Author (s):
Stuart McTaggart

Purpose: The prevalence of type 2 diabetes is strongly correlated with socioeconomic deprivation, and the most deprived patients in Scotland have been shown to develop the disease up to 20 years earlier than the least deprived patients. Increasing prevalence places a financial strain on resources. Scotland spent £67 million ($87 million) in the fiscal year 2015/2016 on diabetic drug therapies, averaging £288 ($374) per treated patient for the year. With the cost of treatment differing widely between drug classes, there may be significant opportunity for efficiencies if prescribing is optimized. This study analyzed prescribing tendencies across deprivation levels, age, and gender.

Methods: The National Prescribing Information System (PIS) holds a record of all National Health Service prescriptions dispensed in the community in Scotland. This study used PIS to extract anonymized data on all patients who received a pharmacologic diabetic treatment during the fiscal year 2015/2016. Treatments were categorized by drug class, and data was stratified by age, gender, and Scottish Index of Multiple Deprivation (SIMD) decile. The SIMD uses a range of socioeconomic measures to rank small geographic regions by deprivation. The higher the SIMD decile, the less deprived the area is. First the proportion of all treated patients by gender who received each drug class was calculated and compared using z-scores. If $p < 0.05$ and there was a difference of 1% or greater in prescribing between genders, this difference was reported as significant in this study. This method was then repeated to find the proportion of all treated patients in each age band treated with each drug class. Patterns in prescribing between age bands were identified using graphing techniques. Finally the data was analyzed to find the proportion of all treated patients in each SIMD decile treated with each drug class and analyzed using linear regression. If $p < 0.05$ and $r2 > 0.85$, then the difference in prescribing between SIMD deciles was reported as significant in this study.

Results: We identified 232,382 patients who were treated with a pharmacologic diabetic treatment in the fiscal year 2015/2016 . Of these patients 44% were female and 56% were male, and 97.9% of these patients were 25 years of age or older. The proportions of females treated was significantly lower than for males for each of the following drug classes: biguanides (71.4% vs. 74.9%), dipeptidyl peptidase-IV (DPP-IV) inhibitors (12.3% vs. 14.1%), sulfonylureas (31.4% vs. 36.0%), and thiazolidinedione (5.1% vs. 6.6%). Analysis by age band showed that biguanides, sulfolyureas, and DPP-IV inhibitors were the most frequently used in all age bands above 25 years. Rapid and long acting insulins were the most frequently used classes of medication in younger age bands. Drug classes with significant correlation between SIMD and proportions of patients treated included: biguanides ($r2=0.94$), DPP-IV inhibitors ($r2=0.85$), glucagon-like peptide-1 receptor (GLP-1) agonsits ($r2=0.95$), sodium-glucose cotransporter-2 (SGLT-2) inhibitors ($r2=0.93$), rapid acting insulin ($r2=0.97$), long acting insulin ($r2=0.94$), and biphasic insulin ($r2=0.88$). The oral therapies mentioned above and biphasic insulin were slightly more common in lower SIMD deciles, and rapid and long acting insulins were slightly more common in higher SIMD declines.

Conclusion: Our findings broadly indicate that the usage of oral diabetic therapy follows published guidelines. We identified some differences in the use of different drug classes in relation to age, gender, and deprivation. However, without diagnostic data we cannot determine whether these are clinically significant or the result of differences in the proportions of type 1 and type 2 diabetes among the study groups. Further work to investigate this is warranted.

Submission Category: Ambulatory Care

Submission Type: Descriptive Report

Session-Board Number: 2-143

Poster Title: Effect of a total care specialty pharmacy model on adult cystic fibrosis clinical outcomes

Primary Author: Porter Ramsey, University of Kentucky College of Pharmacy, Kentucky; **Email:** porter.lee.ramsey@uky.edu

Purpose: Access remains a barrier for adult cystic fibrosis patients with respect to obtaining the necessary therapies to manage their chronic disease state. Currently, little data is available assessing the impact of a total care pharmacy model on clinical outcomes in the adult cystic fibrosis population. The University of Kentucky has a specialty pharmacy that has implemented a total care pharmacy model for adult cystic fibrosis patients. The primary objective of this study is to identify what effects a total care specialty pharmacy has on clinical outcomes in the adult cystic fibrosis population.

Methods: This study was submitted to the Investigational Review Board for approval. This is a retrospective chart review of cystic fibrosis patients, ages 18 years and older, seen in the Adult Cystic Fibrosis Clinic at the University of Kentucky and enrolled in the University of Kentucky Specialty Pharmacy Total Care services. To be included, patients had to have had all medications filled during calendar years 2013 and 2015 at the University of Kentucky Specialty Pharmacy. . Demographic information, including, genetic mutations and comorbid conditions were collected. Clinical endpoints including, weight, body mass index (BMI), forced expiratory volume in the first second (FEV1), and number of inpatient and outpatient exacerbations were collected pre- and post-enrollment into specialty pharmacy services. Data elements from calendar year 2013 were collected to encompass the pre-enrollment period. The same data was collected for calendar year 2015 to reflect the post-enrollment period. The data was then reviewed to determine how the use of a total care specialty pharmacy model impacts the clinical outcomes of the study population.

Results: During retrospective chart review, 31 patients met inclusion criteria into the study. The average age of patients included in the study was 28 years [range: 19 to 48 years]. Nineteen (61.3%) patients were male with 64.5% of patients being homozygous Phe508del. The most common concomitant disease state was Cystic Fibrosis Related Diabetes. . The 2013 pre-

enrollment period yielded an average FEV1 of 58%. The post-enrollment period yielded an average FEV1 of 54%.. The pre-enrollment period yielded an average weight of 57.5kg and the post-enrollment period yielded an average weight of 60kg. Likewise, the pre-enrollment period yielded an average BMI of 20.9 kg/m2 and post-enrollment average BMI of 21.6 kg/m2. The average number of outpatient and inpatient exacerbations was 0.96 and 1.44 for the pre-enrollment period and post-enrollment period, respectively. The post-enrollment period showed an average number of outpatient exacerbations of 1.52 and inpatient exacerbations of 1.72.

Conclusion: This study highlighted the impact of a total care specialty pharmacy model on clinical outcomes for an adult cystic fibrosis patient population. There was an identified positive impact on weight and BMI, with an average 2.5 kg weight gain and 0.7 kg/m2 increase in BMI for patients enrolled in the specialty pharmacy total care services. Enrollment in services did not show a positive impact on pulmonary function as measured by FEV1 or number of exacerbations. Other factors should be considered that may impact pulmonary function or exacerbation rate, like control of Cystic Fibrosis Related Diabetes.

Poster Title: Hyper-response to clopidogrel in patients undergoing neuroendovascular procedures

Primary Author: Garrett Hile, University of Kentucky College of Pharmacy, Kentucky; **Email:** garrett.hile@uky.edu

Additional Author (s):
Aaron Cook

Purpose: Clopidogrel decreases the risk of stent thrombosis, myocardial infarction, stroke, and death. Numerous factors contribute to variable clopidogrel responses. Patients with poor activation of clopidogrel often have high on-treatment platelet reactivity and are usually switched to an alternative P2Y12 inhibitor. A small percentage of the population is characterized as patients with a hyper-response and may be at increased risk of bleeding. The use of VerifyNow in hyper-responders as a therapeutic drug monitoring tool has not been well described in the literature. The purpose of this study was to describe various methods of dose adjustments in patients with hyper-response to clopidogrel.

Methods: This was a retrospective, cohort study of patients taking clopidogrel prior to an intracranial stent or other neuroendovascular procedures from January 2013 thru June 2016. Platelet reactivity after clopidogrel therapy was evaluated with the VerifyNow PRUTest. Any value less than 100 PRU (P2Y12 reactivity units) was classified as a hyper-response. Data collected included concomitant medications, dosage of clopidogrel, PRU values, and incidence of thrombosis or bleeding. Descriptive statistics were applied to the data as applicable.

Results: Forty-three patients received clopidogrel for neuroendovascular procedures during the study period. Fourteen patients (32.5 percent) were classified as having a hyper-response. Each of the dosing strategies was evaluated in these patients.

Conclusion: The incidence of hyper-response to clopidogrel is frequent enough to warrant testing in patients. Numerous individualized dosing strategies may be reasonable for hyper-responders to clopidogrel.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Evaluative Study

Session-Board Number: 2-145

Poster Title: Medication use evaluation of calcitonin at a large, academic medical center

Primary Author: Natalie Russell, University of Kentucky College of Pharmacy, Kentucky; **Email:** natalie.wesley@uky.edu

Additional Author (s):
Samantha Bochenek
Philip Almeter
Jeremy Flynn

Purpose: Calcitonin is a peptide sequence similar to human calcitonin that antagonizes the effect of parathyroid hormone. Calcitonin quickly reduces the amount of calcium present in the body but only to a small extent. The cost of calcitonin has increased 3,300 percent since 2014. Calcitonin utilization was initially curbed after process improvements were initiated last year. However, recent trends show utilization is still variable. The process improvement guidelines that are used include an automatic 48 hour stop date, rounding protocol, and restriction to symptomatic patients. The purpose of this study is to ensure safe, cost-effective, and appropriate use of calcitonin.

Methods: This is an Institutional Review Board approved retrospective cohort study. Patients greater than 18 years of age who received calcitonin from March 1, 2016 to August 31, 2016 were included. Patients were excluded if intranasal was the route of administration for calcitonin. A predefined data collection form was used and included the following information: patient specific information (indication for treatment, current clinical service, calcium levels, and albumin) and information specific for calcitonin (dose, route of administration, and time of administration). In addition, a chart review was performed to determine duration of therapy and if the patient had symptomatic hypercalcemia. Patients were considered to be symptomatic if they were experiencing one of the following cardiovascular, neuromuscular, renal, gastrointestinal, or skeletal symptoms. Based on the current indications for calcitonin, the utilization was assessed. Appropriate therapeutic use was assessed by reviewing indication for calcitonin use and the patients' corrected calcium levels. Data collection was summarized using descriptive statistics and analyzed for identification of suggested focus areas for quality improvement for calcitonin usage. Cost of therapy was also evaluated.

Results: 21 patients were identified who received calcitonin during the 6-month period. Of those 21 patients, 48 percent of patients (n equals 10) were on the internal medicine service. There were 14 percent of the patients (n equals 3) for surgery and 10 percent of patients (n equals 2) for the pulmonary ICU service. Remaining orders were placed by providers in various other areas. 95 percent of patients (n equals 20) had a documented indication for calcitonin use. 24 percent of patients (n equals 5) received calcitonin longer than 48 hours. In addition, 21 percent of doses (n equals 16) were given that did not follow the rounding procedure, thus there was an additional expense of 17,600 dollars. Lastly, 14 percent of patients (n equals 3) received therapy for an inappropriate indication. These patients were not experiencing symptoms due to their hypercalcemia but still received calcitonin. Overall, 52 percent of patients (n equals 11) received inappropriate therapy based on current institutional guidelines.

Conclusion: The analysis revealed that there was low compliance in regards to guidelines established from prior process improvement initiatives. At this time there are still several areas where pharmacists can improve services to facilitate appropriate use of calcitonin. The suggested services include pharmacovigilance for safety and efficacy, duration of therapy, and verification of appropriate dosing. The recommendations from this analysis include requesting the Information Technology department to design a hypercalcemia oncology specific order set that has a drop down window to facilitate dosing's based on 200 unit increments and review the formulary status of calcitonin.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Evaluative Study

Session-Board Number: 2-146

Poster Title: Gabapentin discrepancy rate compared to controlled and non-controlled substances in an institutional setting following security protocol intervention

Primary Author: James Blackmer, University of Kentucky College of Pharmacy, Kentucky; **Email:** jsbl224@uky.edu

Additional Author (s):
Kimberley Hite

Purpose: Gabapentin (Neurontin®) is an antiepileptic drug that is commonly used off-label for indications such as chronic neuropathic pain and diabetic neuropathy. Concerns of abuse and diversion stemming from outpatients pharmacies have raised concerns that these issues are also taking place in the inpatient setting. As Kentucky considers reclassifying the medication as a controlled substance it is pertinent to understand how the discrepancy rate of gabapentin compares to other medications before and after treating gabapentin as a controlled substance in the automated dispensing cabinet system (ADC).

Methods: In March of 2016 University of Kentucky Healthcare implemented a new protocol treating gabapentin as a controlled substance, even though it is not scheduled at the state or federal level, due to a high level of observed discrepancies in the ADC. The security protocol included stocking gabapentin in secure pockets allowing access to only users with controlled substance authorization and requiring a blind count when accessed. The discrepancy rate, defined as the difference between the amount expected and the actual amount in the ADC over the amount of medication dispensed, 4 months before the implementation of the security protocol was compared to the 4 months following. Data was collected by running a discrepancy report of all drugs stored in the ADC system throughout the health-system and analyzing the data using Excel. Only discrepancies of tablets, capsules, suppositories and films were included for dosage form consistency. The primary outcome of the research is to compare the gabapentin discrepancy rate 4 months before the security protocol was implemented and 4 months after to see if the intervention was effective. The secondary outcome is to compare the discrepancy rates of gabapentin to other controlled and non-controlled substances before and after the security protocol was implemented. The study was deemed exempt by the University of Kentucky Institutional Review Board.

Results: As a non-controlled substance, gabapentin was responsible for the 3rd most frequent discrepancies in the ADC system, following acetaminophen and ibuprofen. The discrepancy rate for gabapentin (2.6%) was over twice as high as for the average of the controlled substances while it was being treated as a non-controlled substance. Once the security protocol was implemented, the number of discrepancies decreased by 568. This represents a 62.2% decrease in discrepancies from the pre-intervention period of the security protocol. Also, the discrepancy rate after the policy was implemented decreased to 0.86% for gabapentin. This was a 66.9% decrease in the discrepancy rate, whereas the decrease in discrepancy rate for non-controlled substances was relatively unchanged.

Conclusion: These results suggest that gabapentin diversion may be an issue effecting inpatient hospital settings. Therefore, more strict policies are recommended in order to minimize the amount of discrepancies when an ADC is used to obtain the medication. This information can be used to inform the pharmacy community on the growing concern for diversion surrounding gabapentin. This data supports the lobbying effort to the Kentucky legislature to reclassify gabapentin.

Submission Category: Emergency Medicine/ Emergency Department/ Emergency Preparedness

Submission Type: Descriptive Report

Session-Board Number: 2-147

Poster Title: Pharmacist interventions to improve medication safety for patients discharged from the emergency department

Primary Author: Justin Tossey, University of Kentucky College of Pharmacy, Kentucky; **Email:** justin.tossey@uky.edu

Additional Author (s):
Abbie Britton
Abby Bailey
Regan Baum
Matt Blackburn

Purpose: Pharmacists play a significant role in preventing medication errors and enhancing the transitions of care. The fast-paced nature of the emergency department (ED) can prevent pharmacists from reviewing discharge prescriptions. This study aimed to examine interventions made from call-backs from community pharmacies and evaluate the errors most commonly associated with prescriptions written for patients discharged from the ED.

Methods: All pharmacist interventions are collected into a RedCap database. Entries from July 2015 to July 2016 were retrospectively reviewed. Only calls from pharmacies requesting clarifications or corrections for prescriptions written by ED providers were included for analysis. Data collected included: date of call, patient age, date of ED visit, medication in question, callback reason, correction made to prescription, and level of training of the prescriber. Pharmacy call back data was aggregated and analyzed to determine trends in prescription errors based on time of year, type of medication, and type of prescriber. Entries were excluded from analysis if the call was related to a prescription from a non-ED provider or if details surrounding the intervention were incomplete or unable to be ascertained.

Results: A total of 552 entries were collected in the one year period from July 2015 to July 2016. More than 85% of call backs occurred within 48 h of discharge from the ED with around half of all pharmacy calls made the same day the prescription was written. The most common types of medications that required pharmacist intervention were antibiotics, analgesics, and antiemetics. Reason for the prescription call back included the prescriber or ordered product

not being covered by the patient's insurance, incorrect quantity, and incorrect instructions. In nearly 10% of entries there were two or more unique problems identified that needed to be addressed. Physician residents averaged 6.5 calls per prescriber while attending physicians and mid-level providers had similar rates of prescription call backs (5.6 and 5.0 calls per prescriber, respectively).

Conclusion: ED pharmacists are in a unique position to help optimize transitions of care and identify opportunities that exist to improve the prescription writing process to prevent future errors. Some interventions include more robust education for prescribers. Other adjustments could be made to computerized order entry systems to suggest common doses and instructions associated with the most commonly prescribed medications. The potential importance of a 24/7 outpatient pharmacy location within the hospital may serve as a stopping point for patients being discharged with prescriptions and aid in error mitigation.

Poster Title: Evaluation of patients requiring crotalidae polyvalent immune fab treatment at an academic medical center

Primary Author: David Blair, University of Kentucky College of Pharmacy, Kentucky; **Email:** davidblair@uky.edu

Additional Author (s):
Regan Baum
Anne Marie Guthrie
Abby Bailey

Purpose: The Viperidae family of snakes including copperhead, cottonmouth, pigmy rattlesnake, and timber rattlesnake are indigenous to many parts of Kentucky including the regions served by our institution. Morbidity can be significant as a result of envenomation and can lead to mortality if treatment is inadequate. Crotalidae polyvalent immune Fab (ovine) is approved for use in patients presenting with envenomation caused by the aforementioned snakes. However, little data exists on patients requiring extended durations of treatment. The purpose of this study is to examine Crotalidae polyvalent immune Fab use and characterize those patients requiring extended durations of treatment.

Methods: The institutional review board approved this retrospective case series. Data were obtained from existing patient records, so no informed consent was necessary. Patients receiving Crotalidae polyvalent immune Fab were identified through pharmacy dispensing records from January 1, 2010 – August 31, 2016. Demographic data were obtained with regards to age, species of snake involved, and location of bite. Treatment data were collected with regards to Snakebite Severity Score, number of vials received, surgical interventions, coagulopathy, and adverse events. Those patients receiving greater than or equal to 10 vials of medication were considered to have received an extended duration of treatment. Data obtained from the general population and the extended duration population were compared.

Results: Pharmacy dispensing records indicated 111 patients receiving Crotalidae polyvalent immune Fab between January 1, 2010 and August 31, 2016. Of the 111 identified patients, 21 were found to receive an extended duration of medication. The average age was 26 years in

those patients not requiring an extended duration of treatment and 33 years in those requiring an extended duration. The age distribution was varied between the two groups with a higher percentage of pediatric patients in the normal duration than extended duration population. Copperheads constituted the majority of bites in both populations but 50% of rattlesnake bites lead to an extended duration of medication. The extended duration population had higher Snakebite Severity Scores (3.5 versus 4.5), received more antivenin prior to arrival (1.3 vials versus 2.5 vials), and received more antivenin in hospital (4.5 vials versus 12.5 vials). Coagulopathy rates were 12% in the general population and 24% in the extended duration population. Surgical intervention was rare in both groups (2 patients versus 1 patient) as well as adverse drug events (2 patients in each group).

Conclusion: Risk factors associated with requiring an extended duration of antivenin therapy were rattlesnake envenomation, higher Snakebite Severity Score at presentation, and coagulopathy. Only a small number of patients treated with antivenin require surgical intervention for management. Adverse drug reactions are uncommon, but may be attributed to receiving larger amounts of antivenin.

Poster Title: Assessing the effect of stroke on medication regimen complexity

Primary Author: Elizabeth Jacobs, University of Kentucky College of Pharmacy, Kentucky; **Email:** e.jacobs@uky.edu

Additional Author (s):
Erika Erlandson
Julia Blackburn
Lynne Jensen
Jimmi Hatton-Kolpek

Purpose: The medication regimen complexity index (MRCI) tool quantifies a patient's medication regimen based on dosing forms, frequency and instructions. This tool may identify those who would benefit from medication therapy management. Hospital visits for adverse drug events were associated with MRCI of greater than 8 while all-cause readmission rates were associated with MRCI ranges of 20 to greater than 33. MRCI has not been examined following acute neurologic injury. The purpose of this pilot study was to analyze whether MRCI was increased following the occurrence of acute stroke in patients qualifying for acute rehabilitation prior to returning home.

Methods: This project was approved by the University of Kentucky institutional review board (IRB). Patient level MRCI values were calculated for 40 patients with acute stroke admitted to an inpatient tertiary care hospital and transferred to a single acute rehabilitation facility. All patients included in this study were discharged home from the acute rehabilitation facility. Admission medication reconciliation forms were used for baseline MRCI and medication discharge teaching forms were used for MRCI calculations upon rehabilitation transfer to home. Demographics included gender, age, National Institute of Health Stroke Scale (NIHSS), Functional Independence Measure (FIM) scores, dysphagia, and, number of medications at each time point. Severe stroke was defined as NIHSS less than 9 at acute care admission. Functional Independence Measures were defined as Independent (FIM greater than or equal to 90); Modified Dependence (37-89) and Complete Dependence (FIM less than 37). MRCI calculations were matched for each subject at the two time points. Student's t-test for paired data and one-way ANOVA were used for statistical analysis.

Results: There were 18 males and 22 females. Mean age was 67 plus or minus 14.5 years. Three subjects had dysphagia. Twenty-one subjects (52.5 percent) were admitted with severe stroke. Upon discharge from acute rehabilitation to home, 16 subjects were completely independent, 23 were moderately dependent and three were completely dependent. Baseline Admission Mean MRCI was 14.5 plus or minus 13.5 and mean number of medications was 7 plus or minus 5.7. At discharge from acute rehabilitation to home, the mean number of medications was 11 plus or minus 3.9 and MRCI was 28 plus or minus 13.8. MRCI means were 27 plus or minus 3.1 with NIHSS less than 9 and 29 plus or minus 3.2 with NIHSS greater than 9. MRCI means were 24 plus or minus 3.4 for Independent FIM scores, 31 plus or minus 2.9 for Modified Dependent FIM scores and 28 plus or minus 7.9 for Complete Dependence FIM scores. There was no association between admission NIHSS or acute rehabilitation discharge FIM scores and MRCI in this small sample. The overall mean change in the MRCI between admission and discharge was 13.5 plus or minus 2.3 (95 percent CI 8.98-18.1, p less than 0.0001).

Conclusion: This pilot study shows a significant and rapid increase in medication complexity regimens following acute stroke. The MRCI at discharge from acute rehabilitation to home was within range of prior reports showing increased risk of medication related hospital readmissions. Medication therapy management should be routinely employed for patients following acute stroke.

Poster Title: Assessment of pharmacist knowledge change by practice site following completion of an online continuing pharmacy educational diabetes management activity

Primary Author: Chelsea Collard, University of Kentucky College of Pharmacy, Kentucky; **Email:** chelsea.collard@uky.edu

Additional Author (s):
Adrienne Matson
Amie Goodin
Anne Policastri

Purpose: Continuing pharmacy education (CPE) programs are crucial in educating pharmacists and maintaining current, evidence-based practices. There is little data available that details whether pharmacist practice setting (health-system, retail, or other) is associated with different levels of pre- and post-test knowledge following online monograph CPE and whether there are similar barriers to implementing changes in practice in these different settings. This study assesses pharmacist change in knowledge after completing an online CPE monograph regarding glucagon-like peptide-1 receptor agonists (GLP-1 RAs) in the management of type 2 diabetes mellitus (T2DM), and determines whether practice setting is a factor in knowledge change.

Methods: An online educational content delivery platform was used to host CPE for pharmacists to convey knowledge regarding management of T2DM using GLP-1 RAs. Participants were given a pre- and post- assessment within the online setting (n equals 3,871) containing five knowledge-based questions based on the activity learning objectives and designed to measure the change in knowledge before and after the activity. Participants (n equals 3,740) also completed an optional evaluation at the end of the activity. The evaluation portion included questions about whether the participant intended to make a change in practice resulting from information learned and to identify barriers to making practice changes. All identifying information from the assessments and evaluations was removed following the educational activity and submitted to the institutional review board for exempt status for this analysis using de-identified data.
Percentage of correct responses was calculated for each question for all participants and again by pharmacist practice setting, where setting was categorized as health-system, retail, or other

practice setting. Change in performance on knowledge assessment from pre- to post- activity was calculated via chi square analysis for each question by practice setting, with a priori significance set at 0.05. Frequency of responses for intentions to make a change in practice and barriers to making a change was calculated by pharmacist practice setting. Analysis was conducted with Stata v12.0 and Microsoft Excel.

Results: Of 3,871 participants, 27 percent were health-system pharmacists, 39 percent were retail pharmacists, and 34 percent were pharmacists practicing in other settings. Statistically significant improvement was demonstrated on all knowledge assessment questions, with pharmacists from each practice setting improving performance at post-assessment on every question (p less than 0.01, all questions). Health-system pharmacists had the highest percent improvement when performance was aggregated for all questions, followed by retail pharmacists. Notably, retail pharmacists showed the highest overall percent improvement in knowledge regarding the mechanism for which GLP 1-RAs improve glycemic control (plus 47.58 percent), followed by health-system pharmacist percent improvement in knowledge regarding differences in GLP-1 RA product formulation (plus 47.04 percent).
The most frequently reported intended change in practice from health-system pharmacists was to educate colleagues about the role of GLP-1 RAs in T2DM management (32 percent) while retail pharmacists (46 percent) and pharmacists in other practice settings (28 percent) most frequently intended to educate patients. The most frequently reported barrier to making a practice change related to GLP-1 RAs was formulary restrictions, according to health-system pharmacists (55 percent) and pharmacists in other practice settings (42 percent). Retail pharmacists report patient ability to pay as the greatest barrier (42 percent).

Conclusion: Pharmacist pre-test knowledge improved after completion of an online CPE monograph regarding GLP-1 RAs as shown through increased post-test knowledge for health-system pharmacists, retail pharmacists, and pharmacists who practice in other settings. By gaining a stronger understanding of GLP-1 RAs, pharmacists may be influenced to implement changes in practice in order to maximize patient care. However, certain barriers to practice change, including cost and formulary restrictions, can impede these practice changes from occurring.

Submission Type: Evaluative Study

Session-Board Number: 2-151

Poster Title: Resumption of direct oral anticoagulant therapy following a gastrointestinal bleed at a single institution

Primary Author: Alicia Nalley, University of Kentucky College of Pharmacy, Kentucky; **Email:** alicia.nalley@uky.edu

Additional Author (s):
Rachel Hanners
Kelly Davis

Purpose: Acute gastrointestinal bleeding (GIB) is recognized as the most common adverse effect in patients receiving long-term anticoagulation therapy. While recent studies have demonstrated that the benefits of restarting warfarin therapy after a GIB outweighs the risks when considering thrombosis, recurrent GIB, and mortality, there are limited studies regarding resumption of direct oral anticoagulants (DOACs) following a GIB. Due to differences in onset, duration and the availability of a reversal agent, it is unclear whether practitioners should resume DOACs and warfarin in a similar manner. Therefore, the risks, benefits, and timing for resumption of DOACs after a GIB require further evaluation.

Methods: Following Institutional Review Board approval, a retrospective cohort study was conducted. All patients admitted to the Lexington VA Medical Center with a GIB while receiving anticoagulation therapy between December 2013 and May 2016 were reviewed. Patients were then divided into 2 groups by type of anticoagulant, either DOAC or warfarin. All patients receiving a DOAC were included while patients on warfarin therapy were randomly selected to obtain a ratio of approximately 1:3 for comparison purposes. The primary outcome for this study was to characterize the practice for resuming DOAC therapy at our facility by comparing the timing for resumption of anticoagulation in patients on DOACs and warfarin following a GIB. Specifically, the percentage of patients resuming anticoagulation within 7 days and 60 days following GIB resolution were compared. The secondary outcome was a comparison of the composite incidence of re-bleeding, thrombosis, or mortality in the 90 days following GIB resolution.

Results: Fifty patients experiencing a GIB while on anticoagulation therapy during this time period were included in this study. There were 12 patients admitted with a GIB while taking a DOAC (n= 10 rivaroxaban, 1 dabigatran, 1 apixaban). There was no significant difference between the percentage of patients resuming DOACs and warfarin within 60 days following GIB resolution (67 vs 79% respectively, p =0.39). Of the patients who resumed anticoagulation, there was no difference in the percentage of patients who resumed within 7 days (75 vs 80%, p= 0.76). The median time for resuming therapy was similar at 3.5 vs 2 days (p = 0.57). Additionally, there was no difference in the composite outcome of re-bleeding, thrombosis, or death within the 90 days following GIB resolution (25 vs 34%, p= 0.73).

Conclusion: This retrospective cohort study found that following an acute GIB, practitioners are resuming DOACs in a simliar manner and time frame as warfarin. Despite pharmacologic differences between DOACs and warfarin, there was no difference in adverse outcomes. Due to our limited sample size, future studies are required to confirm these findings and define the most appropriate timing for resuming DOAC therapy following a GIB.

Submission Type: Evaluative Study

Session-Board Number: 2-152

Poster Title: Evaluation of once daily tobramycin dosing in adult cystic fibrosis patients admitted for a pulmonary exacerbation

Primary Author: Alyssa Gaietto, University of Kentucky College of Pharmacy, Kentucky; **Email:** alyssa.gaietto@uky.edu

Additional Author (s):
Debra Murphy
Robert Kuhn
Elizabeth Autry

Purpose: Tobramycin is part of the antimicrobial regimen used to manage a pulmonary exacerbation caused by Pseudomonas aeruginosa in cystic fibrosis (CF) patients. Staubes and colleagues found that 41% of encounters achieved target peak concentrations, with a 10% incidence of nephrotoxicity. Subjects were on an initial tobramycin dose of 10 mg/kg/day. The University of Kentucky Medical Center utilizes a higher initial tobramycin regimen of 12-13mg/kg/dose every 24 hours. The primary objective of this study is to assess the initial dosing regimen by evaluating peak and trough concentrations. A secondary objective investigates the incidence of nephrotoxicity of the tobramycin therapy.

Methods: This study was submitted to the Investigational Review Board for approval. This is a retrospective chart review of CF patients 18 years and older who received tobramycin therapy for a Pseudomonas aeruginosa pulmonary exacerbation while admitted to the University of Kentucky Medical Center between January 1, 2014 and July 31, 2016. Patients were identified via pharmacy charges for tobramycin intravenous solution and admitted to the Internal Medicine service during the study period. Patients with multiple visits within the study period only had their five most recent visits included for analysis. Other data collected included: patient age, gender, weight, height, dose of tobramycin, dosing adjustments, tobramycin levels, minimum inhibitory concentrations, serum creatinine, forced expiratory volume and concomitant nephrotoxic medications. Patients were excluded if their tobramycin therapy deviated from the dosing regimen of 11.5-13.5mg/kg/day, they had less than two tobramycin concentrations recorded, they had a baseline history of end stage renal disease requiring

dialysis, they had a lung transplant or they were pregnant. The peak concentration was considered therapeutically appropriate if the peak serum concentration was >15mg/L or the peak to MIC ratio was >8. The incidence of nephrotoxicity was assessed by looking for an increase in serum creatinine by 0.3mg/dl, an increase in serum creatinine by 1.5 times baseline or as noted by the RIFLE criteria.

Results: Baseline patient demographics, clinical characteristics, tobramycin data and pharmacokinetic parameters were collected. The primary outcome investigated was the success of the initial tobramycin dosing regimen in achieving the target peak concentration (>15mg/L) and trough concentration (< 0.5mg/L). The secondary outcome investigated was the incidence of nephrotoxicity. Of the 35 patient encounters, 88.6% achieved the target peak concentration and 100% achieved the target trough concentration. Using the RIFLE criteria to evaluate glomerular filtration rate (GFR), 14.3% of patients were at risk of renal injury and zero patients were injured. One patient experienced an increase in serum creatinine by 1.5 times baseline. A total of 4 patients (11.4%) had their baseline serum creatinine increase by 0.3mg/dL or greater.

Conclusion: The current initial tobramycin dosing regimen of 12-13mg/kg/dose every 24 hours at the University of Kentucky Medical Center met target serum tobramycin concentrations.

Poster Title: Characterization of acetylcysteine dosing regimen in obese patients weighing greater than 100 kilograms receiving treatment for acetaminophen overdose

Primary Author: LeeAnn Geraghty, University of Kentucky College of Pharmacy, Kentucky; **Email:** leeann.geraghty@uky.edu

Additional Author (s):
Abby Bailey
Regan Baum

Purpose: Acetaminophen is one of the most widely used medications. Ingestion of large amounts is associated with acute liver failure, acute kidney failure, and death due to the production of the toxic metabolite, NAPQI. N-acetylcysteine (NAC) is an antidote that serves to increase detoxification and limit formation of NAPQI. The Food and Drug Administration approved package insert for intravenous (IV) NAC provides dosing up to 100 kilograms (kg). There are no specific dosing guidelines for patients who are obese. This study serves to characterize a NAC dosing strategy in obese patients—to cap or not to cap doses at 100kg?

Methods: This is a single-center, retrospective analysis of patients who presented to the emergency department at University of Kentucky (UK) HealthCare with acetaminophen overdose requiring treatment with NAC that has been approved by the Institutional Review Board. UK HealthCare does not cap NAC doses at 100kg. Data collection was conducted through REDCap by the Institute for Pharmaceutical Outcomes and Policy. Patient identification for inclusion were identified by pharmacy charges or ICD 9/ICD 10 codes. Inclusion criteria were met if a patient received IV NAC treatment for acetaminophen overdose, weight greater than 100kg, age greater than or equal to 18 years old, and NAC was received from January 1, 2009 to January 1, 2016. Patients were excluded if NAC was used for non-acetaminophen overdose indications, no labs drawn within 24 hours of admission for acetaminophen level or liver function tests, or if the patient was transferred from an outside hospital where NAC treatment had already been initiated. The primary endpoint was to describe the incidence of hepatic injury (AST or ALT greater than 100 IU/L or doubling of AST or ALT during admission) or hepatotoxicity (peak serum AST or ALT greater than 1000 IU/L). Secondary endpoints included characterizing the incidence of adverse events during NAC administration; average total NAC

dose and cost per patient; length of hospital stay; length of Intensive Care Unit (ICU) stay; and mortality.

Results: Nine patients were evaluated (n = 9). The primary endpoint of hepatic injury was present in 5 (56 percent) patients and hepatotoxicity occurred in 4 (44 percent) patients. Secondary endpoints revealed a total incidence of adverse events during NAC administration of 22.2 percent; average total NAC dose and cost per patient was 38,238mg and 5,531 dollars, respectively; the average length of hospital stay was approximately 5 days; the average length of ICU stay was approximately 53 hours; and 100 percent of patients survived to discharge. Further characterization of patients showed 6 (67 percent) males; 2 (25 percent) chronic ingestions, 5 (62.5 percent) acute ingestions, 2 (25 percent) mixed ingestions, 3 (37.5 percent) intentional ingestions; 5 (55.6 percent) required additional bags of NAC.

Conclusion: There are no current guidelines for NAC dosing in obese patients greater than 100kg. Potential advantages to not capping NAC doses include affecting rates of survival to discharge and hospital stay. Potential disadvantages to not capping doses are increased drug costs and greater likelihood of adverse events from increased NAC exposure. It is unclear if using actual body weight for NAC dosing could impact the incidence of hepatic injury and hepatotoxicity by providing larger doses of NAC. Further studies are needed to establish the clinical significance of NAC dosing strategies in patients weighing greater than 100kg with acetaminophen overdose.

Submission Category: Emergency Medicine/ Emergency Department/ Emergency Preparedness

Submission Type: Evaluative Study

Session-Board Number: 2-154

Poster Title: Multicenter retrospective review of characteristics associated with bleeding with the new oral anticoagulants

Primary Author: Alexandria Rydz, University of Kentucky College of Pharmacy, Kentucky; **Email:** acry222@uky.edu

Additional Author (s):
Abby Bailey
Regan Baum
Jessica Yost
Stephanie Justice

Purpose: As with all anticoagulation therapies, the new oral anticoagulants pose a risk for adverse bleeding events that may range from minor to major, or even fatal in severity. Previous studies have developed and evaluated the bleeding risk assessment scores for anticoagulation therapy. However, these scores were mainly evaluated and developed with regards to warfarin. This study will examine the characteristics associated with the occurrence of bleeding events from use of the new oral anticoagulants.

Methods: The study retrospectively looked at patients who presented to the Emergency Departments of Charleston Area Medical Center General or Memorial Hospitals and the University of Kentucky Chandler Medical Center from November 1, 2010 to November 1, 2015. Patients included were diagnosed with a bleed and currently taking one of the new oral anticoagulants including rivaroxaban, apixaban, or dabigatran. A subgroup analysis was also preformed for patients taking antiplatelet medications in combination with new oral anticoagulants. The primary objective for this study is to determine the presence of common characteristics associated with the occurrence of major bleeding events in patients taking one of the new oral anticoagulants in the outpatient setting. The secondary objectives included characterizing the occurrence of gastrointestinal bleeding or intracranial bleeding, use of agents to reverse anticoagulation, intensive care unit length of stay, hospital length of stay, hospital mortality rate, and concurrent use of antiplatelet medications and a new oral anticoagulant at home.

Results: Of the 145 patients included in the primary analysis, major bleeding occurred in 32 patients (22.1 percent), intracranial bleeding in 19 patients (12.6 percent), and gastrointestinal bleeding in 44 patients (29.1 percent). 76 patients (50.3 percent) concurrently received anticoagulant and antiplatelet therapy. In-hospital mortality occurred in 18 patients (11.9 percent), with 60 patients (39.7 percent) requiring admission to an intensive care unit.

Conclusion: The most common type of bleed associated with the use of a new oral anticoagulant was non-major, with a higher rate of gastrointestinal bleeding than intracranial bleeding. This retrospective study may provide the basis for further investigations regarding the bleeding risk associated with the use of new oral anticoagulants as there is no validated scoring tool available at this time.

Session-Board Number: 2-155

Poster Title: Student success may depend more on nurture than nature

Primary Author: Alexandra Ferrante, University of Kentucky College of Pharmacy, Kentucky;
Email: alexandra.ferrante@uky.edu

Additional Author (s):
Joshua Lambert
Markos Leggas
Esther Black

Purpose: To determine whether admissions data can adequately predict student success in the first-year Pharm.D. curriculum and whether monitoring and intervention improve success.

Methods: A systematic evaluation of the literature assessing student success was carried out. We analyzed internal admissions data and first-year outcomes for our pharmacy classes of 2016-19 and conducted an interim evaluation of monitoring and mentoring.

Results: Pre-pharmacy GPA, science GPA, PCAT score, and prior degree status each retain some predictive value regarding success, and combinations of these factors may improve predictive power. There remains a significant, and perhaps insurmountable, gap in identification of metrics that forecast student success. We find that early monitoring and intervention provide an actionable means for enhancing student success.

Conclusion: While quantitative academic measures are important in selecting qualified students from the applicant pool, it appears that more subjective measures applied within an institution may better position students for long term success

Poster Title: Effectiveness of pharmacist managed erythropoietin and iron therapy

Primary Author: Taylor Childress, University of Kentucky College of Pharmacy, Kentucky; **Email:** taylor.childress@uky.edu

Additional Author (s):
Matthew Lane

Purpose: Patients with chronic kidney disease often need supplemental erythropoietin and iron given during dialysis sessions to prevent anemia. Recommended treatment goals have been refined to be more conservative to target hemoglobin levels just high enough to prevent transfusions and avoiding hemoglobin greater than 12 g/dL. For iron, the target ferritin goal is between 100 ng/mL and 1000 ng/mL and transferrin saturation goal is 20 percent to 50 percent. The purpose of this study is to evaluate how effective the current pharmacist managed dosing is at maintaining patients within the target hemoglobin and iron levels in comparison to physician dosing management.

Methods: The institutional review board approved this retrospective review of patients with chronic kidney disease undergoing dialysis at the Lexington Veterans Association Medical Center. Patients were identified from the computerized patient record system. Inclusion criteria included all patients chronically receiving dialysis from March 1 to June 30, 2015 (physician managed) and March 1 to June 30, 2016 (pharmacist managed). Exclusion criteria for this study were veterans not erythropoietin dependent and without end stage renal disease. Data collection included demographics (age, sex, dialysis schedule), laboratory and medication data. The primary outcome was percentage of time patients spent in targeted hemoglobin, ferritin, and transferrin range. Secondary outcomes included time to intervention after level obtained, if dosing was held when hemoglobin was greater than 12 g/dL, and frequency of dose changes. We used descriptive statistics for continuous variables and categorical variables to analyze the outcomes of this study.

Results: From March 1 to June 30, 2015, 28 dialysis patients met inclusion criteria and from March 1 to June 30, 2016, 24 dialysis patients met inclusion criteria. All patients were male. The percentage of patients with targeted hemoglobin range occurred 23.7 percent of the time

under physician management and 27.1 percent of the time under pharmacist management. The percentage of patients with targeted ferritin level was achieved 96 percent of the time under physician management and 94.7 percent of the time under pharmacist management. The percentage of patients with targeted transferrin level was achieved 86.3 percent of the time under physician management and 87.2 percent of the time under pharmacist management. Erythropoietin doses were appropriately held 92.1 percent of the time in physician managed therapy and 95.1 percent of the time in pharmacist managed therapy. It took an average of 108.3 hours to make a dose adjustment under physician management and an average of 12.7 hours under pharmacist management. Physician management recommended erythropoietin dose changes 20.2 percent of the time and iron dose changes 11.3 percent of the time. Pharmacist management recommended erythropoietin dose changes 49.5 percent of the time and 46.8 percent of the time for iron dose changes.

Conclusion: In this study, both physician and pharmacist dosing management showed similar percentage time patients were within targeted levels. Both groups were successful at appropriately holding erythropoietin doses when targeted hemoglobin levels were greater than 12 g/dL. Pharmacist managed dosing was more timely in conducting recommendations after the laboratory level was drawn, but physician managed dosing made far fewer dose changes. However, the documentation for medication changes was not standardized for physicians and was difficult to locate in the electronic medical record.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Evaluative Study

Session-Board Number: 2-158

Poster Title: Outcomes from an inpatient proton pump inhibitor stewardship program

Primary Author: Rebekah Wahking, University of Kentucky College of Pharmacy, Kentucky;
Email: rebekah.wahking@uky.edu

Additional Author (s):
Rachel Hanners
Sean M. Lockwood
Randal Steele
Kelly W. Davis

Purpose: Proton pump inhibitors (PPIs) are useful for the treatment of acid-related disorders. Unfortunately, they are a greatly overused therapy with several long-term adverse effects. To decrease the incidence of PPI overprescribing in an inpatient setting, a PPI stewardship program was created at a single institution.

Methods: This was a retrospective cohort study. Any patient admitted to an internal medicine team at the Lexington VAMC from 3/14/16 to 8/9/16 with a prescription for a home PPI was evaluated by the PPI stewardship team for an appropriate indication for continuation of therapy while hospitalized and after discharge. All patients without an indication for inpatient PPI therapy discontinued treatment and started as needed acid suppressive therapy (AST), with stipulations that providers may resume home PPIs if patients had refractory symptoms. The primary objective of the study was to determine the percentage of patients requiring resumption of their home PPI during hospitalization. Secondary objectives included determining risk factors for the resumption of the PPI and the percentages of patients requiring the use of inpatient AST therapy.

Results: Between 3/14/16 until 8/9/16, 1179 patients were admitted to an internal medicine service. Out of those, 526 (44.6%) were on PPI therapy and PPIs were subsequently discontinued in 216 (18.3%) patients not meeting criteria for inpatient continuation of therapy. Only 8 patients (3.7%) required inpatient resumption of their PPI and 33 patients (15.3%) requested an AST dose. When comparing the patients who required restart versus those who did not, home daily dose was significantly higher for the resumed group (47.5mg vs. 32.0mg, p=

0.03). There were no significant differences in duration of PPI use, age, or BMI; although, there was a trend towards a higher BMI in the resumed group (33.5 vs. 29.5, p=0.10).

Conclusion: Many patients admitted to a hospital without a clear indication for a home PPI can discontinue therapy with minimal tolerability issues and AST use while hospitalized. However, care should be taken when discontinuing higher doses of PPIs. Future studies will be needed to evaluate an optimal discontinuation plan for this population and to evaluate the continued success of this program post-discharge.

Submission Category: Pain Management

Submission Type: Evaluative Study

Session-Board Number: 2-159

Poster Title: Reduction in opioid prescribing for pain management upon discharge in trauma surgery patients due to pharmacist-led educational programs de-emphasizing narcotics

Primary Author: David Li, University of Kentucky College of Pharmacy, Kentucky; **Email:** lidavid24@uky.edu

Additional Author (s):
Douglas Oyler

Purpose: Patients admitted to an inpatient trauma surgery service often receive significant pharmacological analgesia upon discharge. Effective management of pain in these patients can result in improved recovery and quality of life; however in light of the trend of increasing opioid consumption, abuse and misuse, an opportunity is presented to pharmacists to curb this problem while maintaining effective pain management. The purpose of this study was to determine whether a pharmacist-led educational program de-emphasizing opioid analgesics and including non-narcotic analgesics in the management of pain could result in significant decreases in opioid prescribing to patients upon discharge.

Methods: The institutional review board approved this retrospective pre-post intervention study. Patients greater than 18 years of age admitted to a level one trauma center with orthopedic injuries in 2013 and 2015 who received at least 1 dose of any opioid analgesic were included. Patients with abdominal operation during admission, severe traumatic brain injury, or a history of illicit drug use were excluded. Pregnant patients were also excluded. The pharmacist-led education program commenced in 2014 and consisted of multiple sessions with attending physicians, monthly to bi-monthly sessions with resident physicians, and two optional web-based training sessions for nurses. The primary outcome of this study was discharge morphine milligram equivalents (MME) per day for all patients. Secondary subgroups included MME/day upon discharge of patients who were receiving at least 30 MME/day on admission and patients who were opioid naïve on admission (admission MME/day of 0).

Results: A total of 913 patients were admitted (489 in the 2013 cohort and 424 in the 2015 cohort). The mean morphine milligram equivalent per day upon discharge of the 2013 group patients prior to the pharmacist led educational program being initiated was 99.34 mg/day. The

mean MME/day upon discharge of the 2015 group patients after the program had been in place for 4 months was 68.25 mg/day, representing a 31.2% decrease in MME/day prescribed upon discharge. Within the 2013 group, patients who were admitted with a MME/day of 0 had a mean of 90.5 MME/day upon discharge while the 2015 group opioid naïve patients were discharged with a mean of 52.3 MME/day, representing a 42.2% decrease after the program had been in place. Patients who were on at least 30 MME/day had an average increase of 42.3 MME/day on discharge as compared to admission in the 2013 group and an average increase of 46.0 MME/day in the 2015 group on discharge as compared to admission, representing a mean increase of 3.7 MME/day.

Conclusion: The implementation of a pharmacist-led program de-emphasizing use of opioids and inclusion of non-opioid analgesics in trauma surgery patients resulted in a significant decrease in the prescribing of opioids upon discharge, which was even more pronounced in opioid naïve patients. In patients who were admitted with at least 30 MME/day, no decrease in 2015 compared to 2013 suggests a decrease in discharge opioids may not be as feasible in this population using only patient and provider education.

Poster Title: Effect of Hospital Stay Duration in Patients Treated with Aztreonam vs. Cefepime for Gram Negative Empiric Therapy: Interim Analysis

Primary Author: Kristopher Ravin, Husson University School of Pharmacy, Maine; **Email:** ravink@husson.edu

Additional Author (s):
Anthony Casapao

Purpose: Penicillin allergies are the most common drug allergies with a prevalence between 8 and 12%. Furthermore, 90% of patients with documented allergies to penicillins are able to tolerate these drugs after a formal evaluation. Many guidelines recommend the use of beta-lactams for gram-negative coverage and avoiding these drugs has been associated with worse clinical outcomes. Patients with these allergies are frequently given aztreonam for gram-negative coverage. The purpose of this study was to compare the effect of hospital stay duration in patients treated with aztreonam vs. cefepime.

Methods: This was a retrospective cohort of patients at Eastern Maine Medical Center in Bangor, Maine between January 2012 and July 2016. Patients ages 18 and older were enrolled if they were treated with aztreonam or cefepime as initial gram negative coverage for a minimum of 72 hours. Patients were matched based on type of infection. Other patient characteristics collected include age, body mass index (BMI), severity of illness at initiation of therapy, comorbid conditions, presence of a beta-lactam allergy, anti-methicillin-resistant Staphylococcus aureus (MRSA) coverage if given, cultured pathogens if available, and site of infection. The primary outcome was duration of hospital stay. Secondary outcomes included clinical failure at 96 hours (defined as changing to a different agent with similar coverage or clinical worsening of illness), 30 day all-cause mortality, appropriateness of therapy based on type of infection, and appropriateness of therapy based on allergy status. A sample size of 160 in each group was calculated to achieve a power of 80% and a 2-tailed alpha of 0.05. For this interim analysis of 80 patients in each arm, a P-value of 0.025 was considered to be statistically significant. Sensitivity analysis was performed based on beta-lactam allergic status.

Results: A total of 160 patients were screened and evaluated for inclusion. The mean age of the population was 67.85 (±13.6) with 75 (46.9%) being male and 85 (53.1) being female. The severity of illness at initiation of therapy was similar between the aztreonam and cefepime with median APACHE II scores of 11 (2-42) and 11.5 (2-41). Pneumonia was the most common type of infection with 53 (66.3%) patients in each group. Majority of patients (81.25%) received anti-MRSA coverage with the vancomycin (76.9%) being the most commonly used agent. The median length of stay for all patients was 9 days (3-42 days). There was no difference in duration of stay between aztreonam and cefepime (9 days versus 9.5 days; P=0.4839) in the primary analysis nor was there in the Kaplan-Meier analysis (P = 0.0769). There was no difference in clinical failure at 96 hours between aztreonam and cefepime (31.3% versus 25%; P=0.3793), 30 day all-cause mortality (17.5% versus 30%; P=0.0632), or appropriate empiric therapy (85% versus 95%; P=0.0623). There was a difference in appropriateness of therapy based on allergy status (45% versus 98.8%; P < 0.0001).

Conclusion: Based on this interim data, there was no statistically significant difference in the duration of hospital stay in treatment with aztreonam compared to cefepime. Though it wasn't statistically significant, there was a higher rate of 30 day all-cause mortality with cefepime compare to aztreonam. Based on the sensitivity analysis, majority of patients receiving aztreonam (55%) could have used a beta-lactam for gram negative coverage. A limitation of this study is the lack of matching patients based on culture pathogen. Future studies controlling for this would be beneficial to determine if there is really no difference in outcomes between treatment groups.

Poster Title: Use of drug information mobile applications by Maine pharmacists

Primary Author: Elizabeth Burnham, Husson University School of Pharmacy, Maine; **Email:** burnhame@husson.edu

Additional Author (s):
Robert Baker

Purpose: The purpose of this survey was to determine the use of drug information (DI) mobile applications by pharmacists licensed in the State of Maine and to determine possible barriers to their use.

Methods: A Google Forms survey was developed in conjunction with the Director of Assessment at the Husson University School of Pharmacy. Comprised of five sections, the survey gathered data on respondent demographics, mobile application use, access to DI mobile applications, usefulness of DI mobile applications, and barriers to the use of DI mobile applications. Branching techniques directed respondents to the appropriate questions. The Maine Board of Pharmacy provided the list of all registrants. The list was manually scrubbed to create a list of individual pharmacists. This anonymous, confidential survey was sent to pharmacists licensed in Maine starting on September 8, 2016. A tickler notice sent on September 20, 2016. The survey closed at 11:59 PM on September 29, 2016. Respondents could enter a drawing for a $25 gift card as an incentive to participate in the survey.

Results: The survey was sent via email to 2,372 licensed pharmacists in Maine; 63 addresses failed. The response rate among those with current email addresses was 5.8% (n=135). Respondents were evenly matched by gender; 59% were over 45 years-of-age; 48% were in community practice; and 42% were preceptors for a college/school of pharmacy. Overall, 73% of respondents reported using mobile applications (e.g., Facebook or Weather.com) on a regular basis while 9% reported never or almost never using them. Forty percent of respondents use DI mobile applications on a regular basis at their practice site; 36% never or almost never do so. Fifty-two percent of respondents reported DI mobile applications as a preferred method of gathering drug information. Sixty-eight percent agreed or strongly agreed that their work site provides adequate access to DI mobile applications, most commonly

Lexicomp, Clinical Pharmacology, and/or UptoDate. Lexicomp was noted to be the most useful. Nearly two-thirds of respondents reported that they do not use mobile applications or that they only download free DI mobile applications. The biggest barriers to using DI mobile applications were the availability of Wi-Fi (36%) and cost (34%).

Conclusion: Maine pharmacists appear to be using mobile applications, though fewer are using DI mobile applications. The majority of respondents use DI applications at their worksite and report that the worksite provides adequate access to them. More Maine pharmacists report the Lexicomp application as useful than any other DI mobile application. A majority of Maine pharmacists report only downloading free mobile applications. The biggest barrier to using DI applications is the availability of Wi-Fi and cost. This study was limited by the low response rate and a resulting sample that may not be representative of the population of pharmacists in Maine.

Poster Title: Pharmacists, student pharmacists and pharmacy technicians prevent adverse drug events by making clinically significant changes to home medication lists on hospital admission

Primary Author: Christine Lin, University of New England, Maine; **Email:** clin1@une.edu

Additional Author (s):
Maria Luisa Nazareno
Nancy Nystrom
Linh Dang
Leslie Ochs

Purpose: Medication errors occurring during hospital admission result from incomplete or inaccurate medication histories. These errors can lead to reduced quality of care and increased costs. Medication history and reconciliation is required during the hospital admission process and can be completed by any health care team member. Pharmacists, student pharmacists and pharmacy technicians are skilled in conducting patient interviews and completing the best possible medication histories at hospital admission. The goal of this quality improvement project was to identify clinically significant changes made to patients' home medication lists upon completion of the medication history process by the pharmacy team.

Methods: Student pharmacists conducted a retrospective review of patients who were admitted into the hospital and interviewed by the Pharmacy Medication Transitions team between September and November 2015. Pharmacists, student pharmacists, and pharmacy technicians followed a standardized format of prioritizing patients, conducting an interview, and confirming medications sources to construct an electronic medication list. The final step in the medication history process was the documentation in a note template that included pertinent information from the interview including who was present, sources used to confirm the medications, all medication changes made to the electronic list, medication access or adherence issues and the final medication list. The completed medication history, home medication list and documentation was reviewed and verified by a licensed pharmacist. Medication changes to home lists were tracked and categorized as additions, removals or changes to medication entries on the original list related to formulation, strength, dose or frequency. These changes were further evaluated for their potential to result in an adverse

drug event or impact the clinical management or outcome during hospital admission. The criteria used to determine clinically significant changes included incorrect formulation, strength, dose, frequency and those medications that were discontinued or added. Lastly, clinically significant changes were further categorized into pharmacological classes.

Results: During this time period, the Medication Transitions Pharmacy team interviewed 854 admitted patients. Of these patients, 42% were categorized as high-risk patients based on age, comorbidities, polypharmacy and anticoagulant use. Eighty percent of admitted patients reviewed had clinically significant changes made to their medication list. For the 5971 medications changes made to home medication lists, 2657 (44.5%) changes were determined to be clinically significant. The most common medication class errors involved psychoactive medications (16.79%), anti-hypertensive medications (15.88%), and pain medications (13.29%). Medication errors due to inaccurate medication lists can lead to increased length of hospitalization and potential readmission; it was noted that 38% of the 854 patients reviewed were readmissions.

Conclusion: Pharmacy teams can improve quality of patient care and decrease medical costs by preventing adverse drug events. Pharmacists', student pharmacists', and pharmacy technicians' involvement in the medication history process improves accuracy of medication lists resulting in reduced medication errors on admission and at discharge. Pharmacy students and staff dedicated to the transitions of care process are better equipped with medication knowledge and experience in building the best possible medication history. Student pharmacists and pharmacy technicians are valuable resources in helping to make clinically significant changes to patients' medication lists.

Session-Board Number: 2-163

Poster Title: Evaluation of calcitonin utilization in a tertiary healthcare setting

Primary Author: Nicolas LaPlante, University of New England, Maine; **Email:** nlaplante@une.edu

Additional Author (s):
Bret LaForge
Matthew Marston

Purpose: Calcitonin is an efficacious method for acutely treating patients experiencing hypercalcemia. However, the cost has dramatically increased in recent years resulting in a significant financial burden to medical facilities and patients if used improperly. This drug-use evaluation was completed with the objective of eliminating unnecessary calcitonin use and creating a hospital-wide order set to encourage responsible prescribing of calcitonin for hypercalcemia.

Methods: A retrospective analysis was conducted for all patients who had a calcitonin order entered during the 2.5 year period from 01/01/2014 to 06/01/2016. All patients who received at least one dose were subdivided per the following indications; hypercalcemia, osteoporosis vertebral compression fractures (OVCF), and osteoporosis. Literature research and guidelines were analyzed to determine the appropriateness of each indication. Using clinically accepted indications and duration of use (tachyphylaxis occurs after 48 to 72 hours of use), an analysis was conducted to discern savings, had prescribing restrictions existed during the study period. Finally, an order set was developed to implement prescribing restrictions and encourage responsible use of calcitonin in hypercalcemia of malignancy. Physicians, nursing, clinical pharmacist specialists, and laboratory personnel were consulted regarding the order set, which was based upon current literature and prescribing restrictions from other surveyed hospitals.

Results: There were 68 calcitonin orders placed over the 2.5 year period, which resulted in 32 patients with at least 1 documented dose. Of those 32 patients, 24 were being treated for hypercalcemia, 7 for OVCF, and 1 for osteoporosis. Eight of the hypercalcemia patients and 3 of the OVCF were treated for a duration greater than 2 days. Osteoporosis was ruled out as an appropriate indication due to the lack of documented efficacy, as well as the correlation

between long-term use and malignancies. Calcitonin was determined to be a last line option for OVCF in light of cheaper alternatives. Overall, it was estimated that if calcitonin use was restricted to treatment of hypercalcemia and limited to a duration of 48 or 72 hours, the hospital could have saved $98,700 or $81,900, respectively. The resulting order set for hypercalcemia of malignancy reflected these restrictions, placing a 72 hours maximum duration on injectable calcitonin. The order set also recommends the laboratory evaluation of ionized calcium rather than total serum calcium. Ionized calcium is not affected by multiple myeloma, which can present with falsely-elevated calcium levels and could lead to the over diagnosis of hypercalcemia of malignancy.

Conclusion: An order set was developed to encourage prudent prescribing of calcitonin for hypercalcemia of malignancy in a tertiary healthcare center. The order set was based on a medication-use evaluation estimating that $81,900 could have been saved over a 2.5 year period by restricting the duration of calcitonin use to 72 hours and utilizing it only in appropriate patient populations.

Poster Title: Feasibility study of a kindergarten through grade 12 (K-12) educational intervention on cannabinoids and the brain: Refinement among college students.

Primary Author: Marcus Zavala, University of New England, Maine; **Email:** mzavala@une.edu

Additional Author (s):
Linh Tran
Erin Kany
Christian Teter

Purpose: K-12 addiction educational outreach has grown in New England in recent years. Members of the College of Pharmacy from the University of New England (UNE) have contributed to these efforts. Despite these efforts, there is a paucity of evidence examining the efficacy of these interventions. Our objectives were to conduct our cannabinoid intervention among college students to examine the feasibility of our approach and refine our methodology prior to entering K-12 schools. We hoped to gain a better understanding of the complexity of our intervention in relation to grade-level ability before administering it to our target population of adolescent students.

Methods: This study was approved by the UNE Institutional Review Board (IRB). Our participants were UNE college students ages 18 years and older, who voluntarily participated in our cannabinoid intervention. The intervention consisted of three phases: Phase 1 (pre-assessment), Phase 2 (cannabinoid mini-lecture with activities), and Phase 3 (post-assessment). Our cannabinoid intervention was designed from publicly available and vetted materials from the National Institute on Drug Abuse (NIDA; https://teens.drugabuse.gov/). Sixteen pre and post assessment questions were compared to assess change in outcomes. Students were given the option to skip any question during either assessment. The primary outcome measure was derived from multiple "risk of harm" items taken from the Monitoring the Future Study (Johnston et al, 2016). For example, students were asked: "How much do you think people risk harming themselves physically and in other ways when they smoke marijuana once or twice a week?" Responses included "no risk," "slight risk," "moderate risk," and "great risk." These responses were collapsed into "no risk" versus "any risk." Secondary outcomes included cannabinoid content knowledge and feedback regarding the complexity and age-

appropriateness of the material. Since college students were not our final target population to test intervention efficacy, we prospectively chose not to link pre and post assessment data at the expense of lacking statistical analyses. This allowed our team to maintain privacy, confidentiality, and reduced influence of coercion.

Results: We identified various differences between pre and post assessments following our cannabinoid intervention. For example, the percentage of participants that endorsed perceived harm of "any risk" from weekly marijuana use increased from 23 percent (n=9) to 91.6 percent (n=33). There were also increases in the percentage of correct responses within the knowledge of cannabinoid content domain. For instance, an increase from 53.8 percent (n=21) to 97.2 percent (n=35) of respondents correctly identified marijuana as potentially addictive, which was an area specifically targeted in our educational intervention. Participants subjectively reported that our material would be appropriate for grades 9 to 12, but would be particularly beneficial for younger students and early intervention efforts. We identified specific assessment items that provided no useful information and these have been removed from future assessments.

Conclusion: We distilled nationally available information on the effects of cannabinoids to the developing brain and vetted methods of educating K-12 students. As a result of our pharmacy-initiated intervention, participants demonstrated an increased perception of harm associated with the use of marijuana as well as increased competency of cannabinoid knowledge. Based on student feedback, we have revised our intervention and assessments to ultimately use in the target population of adolescent students. We plan to provide the refined intervention to larger, multiple samples of adolescents and to link the pre and post assessment data to conduct appropriate statistical efficacy analyses.

Submission Category: Ambulatory Care

Submission Type: Descriptive Report

Session-Board Number: 2-165

Poster Title: Primary care visit duration on quality of medication use

Primary Author: Ryan Dang, University of New England, Maine; **Email:** rdang@une.edu

Additional Author (s):
Nancy Moua
Lukas Everly

Purpose: The goal of this research is to evaluate the impact face-to-face time on medication use and how further evaluating this relationship could uncover areas for pharmacists and other healthcare providers to improve patient care in an ambulatory setting. There is growing concern that duration of visits with primary care physicians are decreasing for each individual patient in combination with increased medication usage. Utilizing data provided by the Center for Disease Control and Prevention (CDC), we will determine what correlation may exist between the total number of medications that patients take and how long they spend with their provider.

Methods: Data from 2013 National Ambulatory Medical Care Survey (NAMCS) file was used to perform the analysis. The survey sampled ambulatory care visits to office-based physicians in 22 states and 7 groups formed by their Census divisions. The data includes patients 18 or older who were seen in an outpatient setting by a physician. 2,705 physicians participated in the study and data was collected by Census Field Representative abstraction. They recorded the total number of medications, up to 10, along with how long the provider spent face to face with the patient.

Results: Patient weighting provided in the sample was utilized and a Pearson's Correlation was evaluated using the two variables. The average number of medication patients were on was 4.50 and the average time spent with physicians was 22.36 minutes. Analysis revealed a significant, negative correlation of -0.005 (p < 0.01) with a covariance of -0.195.

Conclusion: Longer visits correlated with patients taking fewer medications. Perhaps providers are more selective in starting therapy or they are under prescribing if they feel rushed with complex patients. This significant correlation shows that visit duration has a subtle impact on

medication use and prescriber habits in ambulatory visits. Further research should be done to evaluate additional factors that impact not only the number of prescriptions provided, but also their appropriateness.

Poster Title: Prescription monitoring program trends among individuals arrested in Maine for diversion or illegal possession of prescription and illicit drugs in 2015.

Primary Author: Kaitlyn Bernard, University of New England, Maine; **Email:** kbernard1@une.edu

Additional Author (s):
Woori Kim
Kenneth McCall

Purpose: The Maine Prescription Monitoring Program (PMP) was developed in 2004 as a way to hinder as well as identify drug abuse, misuse, and diversion. The objective of this study is to evaluate controlled substance prescribing trends available in the Maine PMP among individuals arrested for diversion or illegal possession of substances in 2015.

Methods: This retrospective, cohort study utilized data from the Maine Diversion Alert Program (DAP) and Maine PMP. The study population consisted of arrests reported to the Maine DAP by local police departments and DEA agencies in Maine in 2015. The arrest records and PMP database were made available by the Maine DAP and the Maine Office of Substance Abuse, respectively; both were subject to a data use agreement. PMP records within 90 days prior to the date of arrest (index date) were linked into a single database with the arrest records by first name, last name, date of birth, and gender. A 90 day interval before and after the arrest was chosen because it aligns with the current time-frame for distribution of unsolicited threshold reports generated by the Maine PMP. We investigated whether the individual had at least 1 matching prescription record in the PMP for the substance involved in the arrest within the pre-specified time interval. The secondary data points consisted of the total number of prescriptions, the number of unique pharmacies and prescribers, in addition to the payment method as classified based on the codes in the PMP. The research project was approved by the Institution Review Board (IRB#090915-011).

Results: In 2015, there were a total of 1,999 individuals involved in 2,368 arrest offenses for either prescription or illicit drugs reported by the Maine DAP. The average age of these individuals was 33.9 years, and 1,355 (67.8%) were male. The 3 most common arrest categories

included possession (n=1,409, 59.5%), trafficking (n=483, 20.4%), and aggravated trafficking (n=136, 5.7%). The 5 most common substances involved in these arrests included heroin (655), cocaine (499), buprenorphine (265), oxycodone (214), and benzodiazepines (197). The majority (65.3%) of persons arrested had no record in the Maine PMP within 90 days of the index date. Of those who had PMP records, 124 individuals had a matching prescription for the substance in the arrest record reported by the Maine DAP; the most common being buprenorphine (52), benzodiazepines (34), oxycodone (27), hydrocodone (9), and methylphenidate (9). The majority (54%) of the 124 individuals used 2 or more pharmacies, 46.8% used 2 or more prescribers, and the most common payment method (51.6%) was commercial insurance.

Conclusion: Most individuals arrested for illegal possession or diversion of prescription or illicit drugs had no PMP records within 90 days of the arrest. Traditional red flags for diversion, such as utilizing multiple pharmacies and prescribers were present in the cohort of patients with matching PMP records, while cash payment was less common than other payment methods.

Poster Title: Evaluation of in vitro fluoroquinolone resistance selection in Neisseria gonorrhoeae

Primary Author: Haley Duong, University of New England, Maine; **Email:** hduong1@une.edu

Additional Author (s):
Yang Chen
George Allen

Purpose: Neisseria gonorrhoeae is an urgent threat because of emerging multidrug antimicrobial resistance. Fluoroquinolones are no longer recommended for the treatment of gonococcal infections due to resistance concerns, but in vitro and/or clinical data suggests that newer fluoroquinolones such as gemifloxacin and moxifloxacin have activity against resistant N. gonorrhoeae. Resistance is promoted when antimicrobial concentrations are in the mutant selection window (MSW), the concentration interval between the minimum inhibitory concentration (MIC) and the mutant prevention concentration (MPC), which is a novel susceptibility parameter. We compared the activity of fluoroquinolones against N. gonorrhoeae through determinations of the MPC and MSW.

Methods: A gyrA mutant of ATTC 49226 (m-49226) was studied. MIC testing was performed with an inoculum of 10^5 colony-forming units (CFU). MPCs were derived by culturing 10^{10} CFU of m-49226 on supplemented gonococcal agar with known concentrations above the MIC of each antimicrobial and then measuring the lowest concentration that inhibited mutant growth. The MSW was determined by calculating the difference between the MIC and the MPC. Pharmacokinetic parameters obtained by therapeutic doses of ciprofloxacin (500 mg PO twice daily; fCmax 2.08 mg/L, t1/2 4 hours, AUC(0-24) 19.18 mg-hours/L), gemifloxacin (320 mg PO once daily, fCmax 0.56 mg/L, t1/2 7 hours, AUC(0-24) 3.48 mg-hours/L), levofloxacin (500 mg PO once daily; fCmax 3.93 mg/L, t1/2 7 hours, AUC(0-24) 32.78 mg-hours/L), and moxifloxacin (400 mg PO once daily; fCmax 2.70 mg/L, t1/2 12 hours, AUC(0-24) 28.80 mg-hours/L) were used to calculate the time within the MSW (% of the dosage interval that antimicrobial concentrations fall within the MSW) and the AUC/MPC ratio for each fluoroquinolone.

Results: For m-49226, the MIC/MPC (mg/L) of ciprofloxacin, gemifloxacin, levofloxacin, and moxifloxacin were 0.0625/0.25, 0.0625/1, 0.0625/0.25, and 0.125/0.5, respectively. Concentrations of all of the studied fluoroquinolones except gemifloxacin are predicted to exceed the MPC, and remain above the MPC for the entire dosage interval. Concentrations of gemifloxacin are not predicted to exceed the MPC, and are predicted to fall within the MSW for 92.5% of the dosage interval. Calculated AUC/MPC values for ciprofloxacin, gemifloxacin, levofloxacin, and moxifloxacin are 76.72, 3.48, 131.12, and 57.6, respectively. Thus, resistance to gemifloxacin (but not ciprofloxacin, levofloxacin, or moxifloxacin) is predicted to occur if this antimicrobial is used to treat infections caused by N. gonorrhoeae.

Conclusion: In mutant N. gonorrhoeae, all of the tested fluoroquinolones except gemifloxacin are predicted to prevent mutant selection. As resistance in N. gonorrhoeae continues to be an emergent problem, new antimicrobial therapies are needed. Although fluoroquinolones are no longer recommended for the treatment of gonococcal infections, few alternative antimicrobials with activity against N. gonorrhoeae are available. Further studies of fluoroquinolones, particularly newer agents such as moxifloxacin that have not been adequately studied, are thus warranted.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Descriptive Report

Session-Board Number: 2-168

Poster Title: Isavuconazonium sulfate: new drug review and cost-minimization analysis

Primary Author: Zuha Bajwa, University of New England, Maine; **Email:** zbajwa@une.edu

Additional Author (s):
Bonnie Murphy
Kristen Sciarra
Amy Lugo
Leslie Ochs

Purpose: Isavuconazonium sulfate is a broad-spectrum azole antifungal approved by the Food and Drug Administration (FDA) for the treatment of invasive aspergillosis and mucormycosis. The purpose of this new drug review was to describe the drug's place in therapy, pharmacokinetics, efficacy, and safety profile compared to similar agents in the antifungal class. The review was focused on the indication for invasive aspergillosis. Additionally, a cost-minimization analysis was performed.

Methods: A literature search was conducted including articles published between 2000 and 2016. Randomized controlled trials, systematic reviews, and meta-analyses were the primary sources used. Database searches included: Medline and Cochrane. Additional sources used to search for unpublished studies and ongoing clinical trials included the websites, www.fda.gov and www.clinicaltrials.gov. Also, manufacturer product labeling and Academy of Managed Care Pharmacy (AMCP) dossiers were evaluated. A cost-minimization analysis of isavuconazonium sulfate was performed to assist in making a formulary recommendation. Publically available data sources were assessed for drug costs.

Results: Isavuconazonium sulfate is a prodrug of isavuconazole and works by inhibiting the synthesis of ergosterol, which results in a weakened and dysfunctional fungal cell membrane. Currently, there are no head-to-head studies with isavuconazonium sulfate and other antifungal drugs. Common adverse effects include nausea, vomiting, diarrhea, and headache. Isavuconazonium sulfate demonstrated a better side effect profile resulting in lower rates of discontinuation than comparators due to better tolerability. Isavuconazonium sulfate offers no clinically compelling advantages over existing antifungal agents. Results of the cost-

minimization analysis from least to most cost effective were: isavuconazonium sulfate, posaconazole, and caspofungin. Additionally, isavuconazonium sulfate was more costly than voriconazole and itraconazole.

Conclusion: Based on the cost-minimization analysis, isavuconazonium sulfate was the least cost-effective antifungal. Isavuconazonium sulfate was recommended as non-formulary and non-preferred with additional prior authorization requirements to ensure patients have had an adequate response to more cost-effective alternatives, such as voriconazole, prior to use of isavuconazonium sulfate.

Submission Type: Evaluative Study

Session-Board Number: 2-169

Poster Title: Medication Use in Stroke Patients with Falls in an Acute Rehabilitation Hospital

Primary Author: Van Le, University of New England, Maine; **Email:** vle@une.edu

Additional Author (s):
Catherine Carlson

Purpose: Falls in stroke patients can cause many health related complications such as internal bleeding or hemorrhage, which can lead to high mortality rates. There have been studies that report certain medication classes are major risk factors for potential fall risk. According to a retrospective study of 41 stroke patients in a rehabilitation center, in 89% of falls, the patients were on antihypertensive, hypoglycemic, tranquilizing or neuroleptic drugs. The purpose of this study was to describe the types of medications and frequencies prescribed for stroke patients with recent falls in an acute rehabilitation hospital.

Methods: This study was a retrospective chart review of patients with stroke and documented fall from January to July 2016. Data collected from the electronic medical records included patients' gender, age, diagnosis, date of incident, time of fall, blood pressure and pulse at the time of fall, fall witness, fall assist, fall location, activity at time of fall, fall condition, medications, and time when medications were administered. These data were analyzed and identified for the different types of medication classes prescribed and the most frequently used medication class in the patient population. The medication class with most frequent use was further evaluated for subtypes within the class.

Results: There were a total of 41 patients included in the study: 21 were females (51.2%) and average age was 63.7 years old (range 24-96 years). There were 48 fall events as some patients sustained multiple falls. A total of 489 medications were used in these patients. Of 489 medications, these were the top three drug classes most frequently used: 67 were antihypertensive (14%), 43 were anticoagulants (9%) and 32 were antidepressant (7%). The most frequently used drug class, antihypertensives, was further investigated and then categorized into the top three frequently used subtypes: 25 were beta blockers (37.31%), 15 were angiotensin-converting-enzyme (ACE) inhibitors (22.39%) and 12 were calcium channel

blockers (17.91%). In addition, other types of drug classes prescribed included: 25 hypoglycemic agents (5%), 9 antipsychotics (2%), and 3 benzodiazepines (1%).

Conclusion: From this study, antihypertensive drugs were most frequently used in stroke patients that had fallen at least once followed by anticoagulants and antidepressant agents. Antipsychotics, benzodiazepines and hypoglycemic agents were also prescribed. These drug classes are similar to the study referenced, which stated that their stroke patients were on medications within these classes, in 89% of the falls. Therefore, stroke patients that are on these medications should be monitored carefully and frequently for blood pressure, glycemic control, and cognition status. For future research, medication used in stroke patients without fall events will be compared to the findings from this study.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Evaluative Study

Poster Title: Efficacy and safety of adjunctive dexmedetomidine in the management of severe alcohol withdrawal syndrome in patients admitted to the intensive care unit

Primary Author: Erin Kany, University of New England, Maine; **Email:** ekany@une.edu

Additional Author (s):
Aaron Koch

Purpose: Use of dexmedetomidine, as an adjunct to benzodiazepines, in patients with alcohol withdrawal syndrome (AWS) in the intensive care unit (ICU) is becoming increasingly more common, but conflicting data exists supporting its efficacy and safety in this patient population. Due to inconsistent efficacy data reported in previous studies, adverse event concerns, and elevated costs, this study aimed to evaluate the effects and safety of dexmedetomidine in adult patients with severe AWS in the ICU of a community hospital.

Methods: A retrospective chart review of all patients with a diagnosis of AWS according to ICD-9 or ICD-10 codes admitted to the adult medical intensive care unit between January 1, 2014 and August 31, 2016 was performed. Patients must have been receiving benzodiazepines according to the hospital's symptom-triggered Clinical Institute Withdrawal Assessment for Alcohol Scale, Revised (CIWA-Ar) protocol. The primary outcomes were the difference in mean lorazepam equivalent dose requirements, mean haloperidol dose requirements, and mean CIWA-Ar scores 24 hours before and after dexmedetomidine initiation. Secondary outcomes included mean lorazepam equivalent dose requirements per day on CIWA-Ar protocol, median ICU length of stay (LOS), and median hospital LOS. Secondary outcomes were compared between patients who had received dexmedetomidine as adjunctive therapy to benzodiazepines versus patients who had only received bolus doses of benzodiazepines for AWS management(control group). Safety outcomes assessed in patients who had received dexmedetomidine included the incidence of hypotension (systolic blood pressure less than 90 mm Hg) and bradycardia (heart rate less than 50 beats per minute). The Wilcoxon Sign Rank test was used to detect differences 24 hours before and 24 hours after initiation in the dexmedetomidine group. The Wilcoxon Rank Sum test was used to compare differences between the dexmedetomidine group and the group that did not receive dexmedetomidine.

Results: Thirty-three admissions met criteria for enrollment. Thirteen patients received dexmedetomidine along with benzodiazepines and 20 patients received boluses doses of benzodiazepines only. There were no significant differences in mean lorazepam equivalent dose requirements (14.6 mg vs. 10.9 mg, p = 0.22), mean haloperidol dose requirements (7.7 mg vs. 3.8 mg, p = 0.26), and mean CIWA-Ar scores 24 (9.0 vs. 6.2, p = 0.08) 24 hours after dexmedetomidine was initiated. Benzodiazepine dose per day on CIWA-Ar protocol was similar between groups (Dexmedetomidine: 11.8 mg vs. Control: 10.0 mg, p = 0.14). Hospital LOS was longer in the dexmedetomidine group (Dexmedetomidine: 136 hours vs. Control: 68 hours, p = 0.08) and ICU LOS was significantly longer for patients who had received dexmedetomidine (Dexmedetomidine: 120 hours vs. Control: 64 hours, p = 0.005). Three patients (23 percent) who received dexmedetomidine experienced bradycardia and four patients (31 percent) experienced hypotension. One patient had to discontinue dexmedetomidine due to bradycardia.

Conclusion: Adjunctive dexmedetomidine for the management of severe AWS in ICU patients does not significantly improve CIWA-Ar scores or significantly decrease the need for benzodiazepines or haloperidol. Patients who received dexmedetomidine had a significantly longer median ICU length of stay. Bradycardia and hypotension were also common in patients who received dexmedetomidine Due to the small population, more research is needed to assess the negative impact of using dexmedetomidine in patients with severe AWS.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Descriptive Report

Session-Board Number: 2-171

Poster Title: Cariprazine: new drug review and cost-minimization analysis

Primary Author: Morgan Roy, University of New England, Maine; **Email:** mroy9@une.edu

Additional Author (s):
Nicolas LaPlante
Nicole Withrow
Maxwell Roberts
Kevin Connell

Purpose: Cariprazine is a new second generation atypical antipsychotic (AAP) approved for the treatment of schizophrenia and the acute treatment of manic or mixed episodes associated with bipolar I disorder. The purpose of this review was to define the role of cariprazine in current therapy for the treatment of schizophrenia, considering efficacy, safety, tolerability, and cost.

Methods: The primary sources used for the review included two phase III multinational, randomized, double blind, placebo and active controlled trials and product labeling. Also, systematic reviews and current practice guidelines were evaluated. Other databases searched included: Cochrane Database of Systematic Reviews, Micromedex, Lexicomp, Clinical Pharmacology. Current practice guidelines were obtained from the British National Institute for Clinical Excellence (NICE) and Diagnostic and Statistical Manual of Mental Disorders (DSM) library. Additionally, ongoing clinical trials were evaluated using www.clinicaltrials.gov. A cost-minimization analysis was conducted comparing cariprazine to other similar AAPs within the class. Data was compiled and analyzed to generate a clinical conclusion and formulary recommendation.

Results: Cariprazine is a second generation AAP indicated for schizophrenia and acute treatment of bipolar I disorder. To date, there have been no head to head studies comparing cariprazine to other AAPs. Two pivotal trials showed the efficacy of cariprazine compared to placebo, with clinically significant changes in the Positive and Negative Syndrome Scale (PANSS) for schizophrenia. Clinical considerations for cariprazine include adverse effects such as akathisia, extrapyramidal symptoms (EPS), nausea and vomiting, as well as the contraindication

for use in patients with a CrCl less than 30 mL/min. A cost-minimization analysis was performed comparing cariprazine to other AAPs with the indication of schizophrenia. Cariprazine was the most costly and least cost-effective compared to lurasidone, quetiapine, aripiprazole, olanzapine, asenapine and risperidone, from most to least costly, respectively.

Conclusion: Based on the cost-minimization analysis, cariprazine was the least cost-effective atypical antipsychotic. Cariprazine was recommended as Tier III non-formulary requiring a prior authorization in patients with a diagnosis of schizophrenia who are at least 18 years of age and have failed therapy with both aripiprazole and risperidone.

Poster Title: Antimicrobial stewardship at an acute psychiatric facility: compliance with clinical guidelines for urinary tract infection, upper respiratory infection, and skin and soft tissue infections

Primary Author: Kristen Sciarra, University of New England, Maine; **Email:** ksciarra@une.edu

Additional Author (s):
Haley Duong
Devon Sherwood

Purpose: While useful in certain bacterial infections, antibiotics are often inappropriately prescribed in the hospital setting. Unnecessary or improper use of antibiotics leads not only to increased health care costs, but also increased bacterial resistance. The purpose of this study was to review compliance with current practice guidelines for urinary tract infection (UTI), upper respiratory infection (URI), and non-purulent skin and soft tissue infection (SSTI) to the antibiotic regimens that were prescribed to patients in an inpatient psychiatric hospital.

Methods: The ethics committee at Spring Harbor Hospital has approved this study along with University of New England exempt IRB status. The time of period assessed for chart review was from September 1, 2015 to August 31, 2016. To be included in the study, patients of all ages must have received an oral or intramuscular antibiotic during their stay at Spring Harbor Hospital.
Those prescribed antibiotics for diagnoses other than UTI, URI or non-purulent SSTI (cellulitis) were excluded. Additionally, patients were excluded if antibiotics were prescribed before admission to the hospital. Guidelines were obtained from the Infectious Diseases Society of America as well as the American College of Clinical Pharmacy. Antibiotics prescribed were then compared to treatments recommended by the guidelines.

Results: There were 234 patients who received antibiotics during assessment. After accounting for exclusion criteria, 99 patients were evaluated. Out of 34 patients with uncomplicated UTI, 33 were treated with first line antibiotics (97 percent guideline adherence). A total of 14 patients were diagnosed with complicated UTI: 10 patients treated with first line therapy (71.4 percent adherence to guidelines). This meant a combined 89.6 percent adherence to guidelines

for all UTI. A total of 18 patients were diagnosed with URI, with 10 patients given first line treatment, 1 patient receiving second line treatment (61.1 percent of patients received either first or second line treatments). Out of 33 patients diagnosed with non-purulent SSTI, 17 were given first line treatment and 10 were given second line treatment (81.8 percent adherence to guidelines).

Conclusion: Failure to follow current practice guidelines when prescribing antibiotics often results in increased healthcare costs and bacterial resistance. This retrospective study found a high compliance rate with current practice guidelines for UTI, URI, and non-purulent SSTI (cellulitis). However, additional intervention should be made to ensure 100 percent compliance with guidelines.

Submission Type: Descriptive Report

Session-Board Number: 2-173

Poster Title: Brexpiprazole: new drug review and cost-minimization analysis

Primary Author: Yang Chen, University of New England College of Pharmacy, Maine; **Email:** ychen4@une.edu

Additional Author (s):
Haley Duong
Candace Iba
Nancy Moua
Amy Lugo

Purpose: Brexpiprazole is a new atypical antipsychotic (AAP) approved by the Food and Drug Administration (FDA) for schizophrenia and as adjunctive therapy to antidepressants for Major Depressive Disorder (MDD). The purpose of this new drug review was to describe the drug and compare the efficacy, safety, dosing, and pharmacokinetics of brexpiprazole with similar agents in the AAP class. The review focused on the indication for MDD. In addition, we performed a cost-minimization analysis.

Methods: Randomized, controlled trials, and systematic reviews were the primary literature sources used in this review. Specific databases searched included: MEDLINE, Database of Abstracts of Effects (DARE) and the Cochrane Database for Systematic Reviews. Additionally, clinical trials and systematic reviews from the National Institute for Health and Care Excellence (NICE), Oregon Evidence-based Practice Center Drug Effectiveness Review Project (OHSU), and the Agency for Healthcare Research and Quality (AHRQ) were evaluated. Unpublished studies and ongoing clinical trials from www.fda.gov and www.clinicaltrials.gov were considered in addition to data from manufacturers including product labeling and Academy of Managed Care Pharmacy (AMCP) dossiers. A cost-minimization analysis of brexpiprazole was performed comparing similar agents with the indication for MDD as adjunctive therapy. Drug costs were assessed using publicly available data sources.

Results: Brexpiprazole is an AAP that exhibits partial agonist activity for serotonin 5-HT1A, dopamine D2 and D3 receptors, antagonist activity for serotonin 5-HT2A, 5-HT2B, 5-HT7, and multiple noradrenergic receptors. Brexpiprazole has a high affinity for serotonin, dopamine,

and noradrenergic receptors, and moderate affinity for histamine receptors. This new AAP is indicated for both schizophrenia and as adjunctive therapy to antidepressants in MDD. Compared to placebo, brexpiprazole 2 mg and 3 mg demonstrated statistical and clinically significant differences in lowering Montgomery-Asberg Depression Rating Scale (MADRS) score. Common adverse effects include akathisia, weight gain, and increased serum triglycerides with lower discontinuation rates than comparators due to better tolerability. Brexpiprazole has limited use among elderly patients, pediatric patients, and pregnant women. Results of the cost-minimization analysis from least to most cost-effective were: brexpiprazole, aripiprazole and quetiapine.

Conclusion: Although clinically efficacious, brexpiprazole was the least cost-effective atypical antipsychotic agent based on a cost-minimization analysis. Brexpiprazole was recommended as Tier 3 non-preferred medication with additional prior authorization requirements and quantity limits to ensure patients have had an adequate trial of more cost-effective alternatives first before use of brexpiprazole.

Poster Title: Evaluation of accurate dietary supplement product labeling

Primary Author: Laura Hitchcock, University of New England College of Pharmacy, Maine;
Email: lhitchcock@une.edu

Additional Author (s):
Hoang Pham
Brandon Kong
John Redwanski

Purpose: Dietary supplements and over-the-counter medications (OTC's) do not have to be proven safe or effective before being sold to consumers like prescription medications. Under the Dietary Supplement Health and Education Act of 1994, manufacturers only have to prove their product causes no harm to consumers. Some dietary supplements are known to contain saw dusts, lead, pesticides, arsenic, glass particles, and insect parts. The specific aim of this study is to verify whether dietary supplements and OTC's contain the amount of ingredients claimed on the label of a product.

Methods: The institutional review board approved this evaluation study. University of New England College of Pharmacy faculty, staff, and consumers who consumed dietary supplements were included in this study. Sixteen participants voluntarily shared the names of the dietary products that they use, including product name, manufacturer, and strength. Participants provided their name and email address for follow-up. Sixteen participants shared a total of 54 dietary supplements that were then evaluated. ConsumerLab.com® and the United States Pharmacopeia® (USP) verification system were then used to evaluate if their dietary supplements were approved. ConsumerLab.com® and the USP® are the leading providers of independent test results, which approve whether products are accurately labeled with the correct amount of active ingredients and whether they contain harmful ingredients. Once information was evaluated, participants were contacted and informed whether ConsumerLab.com® or USP® tested and approved their product. The primary outcome measure was percent of dietary supplements used by participants that were approved by ConsumerLab.com® and/or USP®. Secondary outcomes included percentage of dietary

supplements not approved by ConsumerLab.com® and/or USP®, and percentage of dietary supplements not tested by ConsumerLab.com® and/or USP®.

Results: The percent of dietary supplements used by participants that were approved by ConsumerLab.com® was 24.07 percent (13/54 dietary supplements). The percent of dietary supplements used that were approved by USP® was 7.40 (4/52 dietary supplements), and the percent of dietary supplements used that were approved by both ConsumerLab.com® and USP® was 2.04 (1/49 dietary supplements). Percentage of dietary supplements that were not approved by ConsumerLab.com® was 3.70 (2/54 dietary supplements), and there were not any dietary supplements that were tested by USP® and not approved. 72.2 percent (39/54) of the dietary supplements were not tested by ConsumerLab.com® and 92.6 percent (50/54) of dietary supplements were not tested by USP®.

Conclusion: ConsumerLab.com® approved more dietary products used by participants than USP®. ConsumerLab.com® disapproved more dietary products than USP®, since there were not any dietary supplements that were tested by USP® and not approved. Overall, both verification databases failed to provide information on a majority of supplements inspected. Verification systems need to expand their number of supplements tested to give consumers correct information.

Poster Title: Insulin degludec: New drug review and cost minimization analysis

Primary Author: Jennifer Pellegore, University of New England College of Pharmacy, Maine;
Email: jpellegore@une.edu

Additional Author (s):
Consuelo Elder
Christina Curry
Woori Kim
Olha Perkowski

Purpose: Insulin degludec is a novel long-acting basal insulin analog recently approved by the United States Food and Drug Administration (US FDA) to improve glycemic control in adults with type 2 diabetes mellitus (T2DM). The purpose of this new drug review is to describe the place in therapy of insulin degludec as well as to compare the efficacy, safety, dosing, and pharmacokinetics of insulin degludec with similar agents in this class. A cost minimization analysis was performed comparing similar agents.

Methods: The primary sources used for the review included two phase III, multinational, inferiority trials and manufacturer product labeling. In addition, systematic reviews and current practice guidelines were evaluated. Other databases searched included Cochrane and Lexicomp. Additional clinical information was gathered from the Academy of Managed Care Pharmacy (AMCP) dossier, and ongoing clinical trials were evaluated using www.clinicaltrials.gov. To help determine formulary placement, a cost minimization analysis was performed using publicly available data sources to determine drug costs.

Results: Insulin degludec is a long-acting insulin similar in administration and dosing to insulin detemir and insulin glargine. However, insulin degludec has a faster onset, longer duration, and longer stability upon initial use of insulin pen. In two head-to-head trials and a systematic review, participants with T2DM and inadequate blood sugar control at baseline, treatment with insulin degludec provided reductions in HbA1c similar to those achieved with insulin glargine. There were no differences in adverse effects between insulin degludec and insulin glargine,

although insulin degludec may cause less nocturnal hypoglycemia. This drug is well tolerated with common adverse effects including: nasopharyngitis, headache, upper respiratory tract infection, and diarrhea. Cost minimization rankings of medications from the least to the most cost-effective were as follows: insulin glargine, insulin detemir, and insulin degludec.

Conclusion: Despite unique pharmacokinetic parameters and the potential for less nocturnal hypoglycemia, insulin degludec offers no clinical advantages over similar agents used to treat T2DM. Due to high cost, we recommend insulin degludec as non-formulary with additional prior authorization criteria to ensure patients have had an adequate response to more cost-effective alternatives.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Descriptive Report

Session-Board Number: 2-176

Poster Title: Ombitasvir/paritaprevir/ritonavir: new drug review and cost-minimization analysis of a fixed dose-combination antiviral

Primary Author: Sharon Cross, University of New England College of Pharmacy, Maine; **Email:** sehret@une.edu

Additional Author (s):
Meaghan Kelly
Daisy Jacquez
Amy Lugo
Leslie Ochs

Purpose: The US Food and Drug Administration (FDA) approved a fixed dose-combination antiviral containing ombitasvir/paritaprevir/ritonavir to be used in combination with ribavirin for the treatment of hepatitis C virus (HCV) genotype 4 infections in patients without cirrhosis. The purpose of this new drug review was to describe the drug and compare dosing, pharmacokinetics, safety, and tolerability of this fixed dose-combination with current therapies. Additionally, a cost minimization analysis was performed.

Methods: A clinical effectiveness review of antiviral agents indicated for HCV genotype 4 was conducted. Efficacy, clinical practice guidelines, safety, and tolerability were evaluated. Unpublished studies and ongoing clinical trials were considered in addition to data from manufacturers including product labeling and the Academy of Managed Care Pharmacy (AMCP) dossiers. A cost-minimization analysis of the fixed dose-combination was performed comparing similar agents to aid in formulary decision-making. Drug costs were assessed using publicly available data sources.

Results: This fixed dose-combination is the first drug to demonstrate safety and efficacy in the treatment of HCV genotype 4 infections without the need for co-administration of interferon. The tablet includes a NS5A inhibitor (ombitasvir), a NS3/4A protease inhibitor (paritaprevir), and a CYP3A inhibitor (ritonavir) and is given in combination with ribavirin for 12 weeks. This drug combination is a Grade IA recommendation from the American Association for the Study of Liver Diseases (AASLD) for both treatment-naïve and treatment-experienced patients. In

combination with ribavirin, the fixed dose-combination agent achieved a higher sustained virologic response (100 percent) compared to treatment without ribavirin (91 percent). The most common adverse effects were nausea, insomnia, asthenia, fatigue, pruritus and other skin reactions. This drug is contraindicated in patients with moderate to severe hepatic impairment, moderate and strong inducers of CYP3A, and concomitant use with ethinyl estradiol-containing products. Results of the cost-minimization analysis from least to most cost-effective were: sofosbuvir, ledipasvir/sofosbuvir, ombitasvir/paritaprevir/ritonavir, and elbasvir/grazoprevir.

Conclusion: Although clinically efficacious, ombitasvir/paritaprevir/ritonavir was not the most cost-effective agent. The fixed dose combination was recommended as a Tier 2 non-preferred medication with additional prior authorization requirements including patients who have failed treatment with elbasvir/grazoprevir or have contraindications to other first line agents used in the treatment of HCV genotype 4 infections.

Submission Type: Descriptive Report

Session-Board Number: 2-177

Poster Title: Improved Quality of Medication Histories Performed by a Student Pharmacist with Prior Training in a Transitions of Care Elective Course

Primary Author: Aimee Nordmeyer, University of New England College of Pharmacy, Maine;
Email: anordmeyer@une.edu

Additional Author (s):
Lisa Wendler
Leslie Ochs
Nancy Nystrom

Purpose: Medication histories are generally performed by hospital staff with limited knowledge of pharmacy practices. The purpose of this added service is to demonstrate the effectiveness of an Advanced Pharmacy Practice Experience (APPE) pharmacy student obtaining best possible medication histories (BPMH) in a large teaching hospital. With improved medication histories, potential adverse drug events can be prevented during admission.

Methods: A group of eight third year pharmacy students completed an elective course titled, "Transitions of Care in Pharmacy" during the fall semester of 2015. The elective course focused on obtaining the best possible medication history for patients admitted to the emergency department. Patients were selected by using scoring tools which categorized them based on low, medium, or high risk. During the course, students were trained to use proven interview techniques, and contact available resources to confirm medication fill history with pharmacies, healthcare providers, and electronic health records to build the BPMH. Having completed the didactic course work and practical training, the student pharmacist applied these skills during a subsequent APPE rotation with an Adult Medicine Team. The student pharmacist conducted medication histories for patients admitted to the medicine team who had not received a prior BPMH by a pharmacist or intern in the emergency department. Medication errors or discrepancies found on the patient's medication list were shared with the medicine team during clinical teaching rounds and documented in the electronic medical record system. The medicine team service population included all patients admitted to the Adult Medicine team at Maine Medical Center in Portland, Maine from May 16 to June 24, 2016.

Results: Thirty-five medication histories were completed during the six-week APPE rotation. Of these medication histories, a total of 408 medications were reviewed and resulted in 117 clinically significant changes. The clinical changes were tracked and categorized as medications removed from, added to or changed on the prior to admission (PTA) medication list in the electronic medical record. The third category, number of medications changed, contained medications on the patient's PTA list, that had either the incorrect dosage, directions, or formulation. Of the thirty-five medication histories completed, 94 medications were removed, 65 medications were added and 84 medications were changed from the patients' PTA lists.

Conclusion: Prior training in a transitions of care elective during the third professional year of pharmacy school improved the quality of medication histories performed during an acute care APPE rotation. Based on these results, the training during the third professional year of pharmacy school serves as both a valuable learning experience and an important contribution to the quality and safety of a patient's hospital admission. This practice model should be considered a standard in the future of pharmacy education.

Submission Category: Practice Research/ Outcomes Research/ Pharmacoeconomics

Submission Type: Descriptive Report

Session-Board Number: 2-178

Poster Title: National survey of pharmacokinetic and therapeutic drug monitoring activities of practicing pharmacists throughout the United States

Primary Author: Sara Tyburski, University of New England College of Pharmacy, Maine; **Email:** sbond5@une.edu

Additional Author (s):
Emily Dornblaser

Purpose: Performance-based measures are key for guiding clinical pharmacokinetics' course design in pharmacy graduate programs. This survey was used to determine which medications undergo pharmacokinetic (PK) monitoring with the use of calculations, which undergo therapeutic drug monitoring (TDM) without the use of calculations, and also to describe the specific methods used for each by practicing pharmacists, so that curricula may be tailored to best prepare students for real-world practice.

Methods: A thirteen-question electronic survey was developed, then approved by the institutional review board (IRB). It was created through SurveyMonkey and distributed via the American Society of Health-System Pharmacists' (ASHP) discussion boards. Follow-up posts were made at week 3 to maximize response and the survey closed at 6 weeks. Total responses were tallied and analyzed on a national, as well as regional basis.

Results: Final analysis was conducted on 340 completed responses from 47 states. Data showed that vancomycin (88% of all respondents), aminoglycosides (84%), phenytoin (58%), and digoxin (44%) most commonly require PK calculations in clinical practice. Interestingly, medications with the highest frequency of calculations (>10 times/week) included vancomycin (35%), aminoglycosides (3%), and cyclosporine (2%). The most common method of PK monitoring is 'calculating by hand'. Most TDM is performed on warfarin (86%), enoxaparin (78%) and other anticoagulants (79%), vancomycin (65%), and aminoglycosides (59%), with the two most common methodologies being 'use of clinical judgment' and 'institutional protocols'.

Conclusion: The actual practices of working pharmacists should drive curricula of clinical pharmacokinetics courses, and in order to assure relevant performance measures for students,

PK and TDM activities of pharmacists must be thoroughly evaluated. Results of our survey indicate that frequency of PK calculation does not reflect the overall likelihood of a calculation being performed in any setting. Instead, medications requiring most frequent calculation are perhaps only found in specialty sites (ex. Cyclosporine). An "ever-exposed" metric would be a more accurate assessment of whether competence in managing a medication must be specifically addressed prior to student integration into general practice.

Submission Type: Evaluative Study

Session-Board Number: 2-179

Poster Title: Susceptibility of Pseudomonas aeruginosa bloodstream isolates in Maine and the implications for selection of empiric antibiotic regimens

Primary Author: Nathan Laliberte, University of New England College of Pharmacy, Maine; **Email:** nlaliberte1@une.edu

Additional Author (s):
MJC Min
Anthony Casapao
Minkey Wungwattana

Purpose: Pseudomonas aeruginosa (P. aeruginosa) bacteremia is associated with prolonged hospitalizations, intensive care unit stays, high morbidity and high mortality. This highlights the need for proper empiric antimicrobial selection and antimicrobial stewardship. Resistance patterns can be elucidated through detailed analysis of susceptibility data, culminating in the construction of an antibiogram. This allows healthcare providers to quickly optimize therapy, thereby improving patient outcomes. The aim of this study was to analyze susceptibility of P. aeruginosa bloodstream isolates collected at institutions in Maine, in an effort to define optimum empiric monotherapy agents.

Methods: Patients with positive blood cultures for P. aeruginosa between 2008 and 2016 at multiple institutions in Maine were identified. All patients with P. aeruginosa positive blood culture results were included in this analysis. Following a screening process to identify patients with positive blood cultures for P. aeruginosa, the following data were collected: gender, age at time of positive blood culture, height, weight, hospital location, Pitt bacteremia score, source of infection, selected antimicrobial therapy, susceptibility data and information describing patient outcomes. All data was de-identified and archived in a secure database for analysis. Descriptive statistics were performed on baseline characteristics and susceptibility data.

Results: A total of one hundred and thirty five patients with positive blood cultures for P. aeruginosa were identified from patients at multiple hospitals in Maine. Susceptibility data for ten agents with known activity against P. aeruginosa were included in this study. Observed susceptibility data is as follows (presented as susceptible isolates over total number of isolates,

followed by percent susceptibility): Amikacin 131/131 (100), tobramycin 130/131 (99.2), gentamicin 128/131 (97.7), ceftazidime 112/115 (97.4), cefepime 127/131 (97), meropenem 123/131 (94), levofloxacin 77/85 (90.6), piperacillin-tazobactam 117/131 (89.3) ciprofloxacin 106/125 (84.8) and aztreonam 103/131 (78.6).

Conclusion: Amikacin, tobramycin, gentamicin, ceftazidime, cefepime, meropenem and levofloxacin exhibited greater than 90 percent susceptibility against P. aeruginosa isolates. Piperacillin-tazobactam empiric monotherapy may no longer be sufficient. The 2016 Infectious Diseases Society of America hospital acquired pneumonia/ventilator acquired pneumonia guidelines recommend adding a second agent when using agents with less than 90 percent susceptibility. Ceftazidime, cefepime and meropenem are likely the best empiric monotherapy candidates for the treatment of P. aeruginosa bacteremia in Maine. Further evaluation of outcomes in patients receiving monotherapy when susceptibility is greater than or equal to 90 percent should be conducted to better define optimum empiric monotherapy.

Poster Title: Exploration of the clinical impact associated with the contributing factors that influenced clinical inertia at the Maine medical partners-endocrinology and diabetes center (MMP-EDC)

Primary Author: Andres Sedano, University of New England College of Pharmacy, Maine; **Email:** andres.sedano@yahoo.com

Additional Author (s):
Brittany Durgin
Kristen Bruell
Corinn Martineau

Purpose: When managing patients with diabetes mellitus (DM), the failure to intensify therapy when the target hemoglobin A1c (HbA1c) is not achieved after approximately 3 months is referred to as clinical inertia, per current American Diabetes Association (ADA) guidelines. While clinical inertia is known to lead to long-term health problems, the clinical impact associated with contributing factors that influenced clinical inertia remains unclear. The purpose of this quality assurance review is to explore the clinical impact associated with the contributing factors for clinical inertia to elucidate the implications of therapeutic decisions that deviate from the ADA guidelines.

Methods: We performed a detailed retrospective review of electronic medical records to identify the contributing factors for clinical inertia and to determine if the decision to waive treatment intensification led to a negative clinical impact. Data was collected from a previous study at the MMP-EDC which found the incidence of clinical inertia to occur 34 percent of the time. 116 study cases with Type 2 DM presenting to the MMP-EDC from January 1, 2015 through August 1, 2015 were considered. Inclusion criteria: diagnosis of Type 2 DM, greater than or equal to 18 years of age, therapy managed medically, HbA1c greater than or equal to 7 percent. Exclusion criteria: greater than 75 years of age, pregnancy, less than 2 HbA1c readings within study window. Contributing factors defined as 1) concordance: therapy intensification when HbA1c greater than or equal to 7 percent, 2) true non-concordance: lack of concordance when HbA1c greater than or equal to 7 percent with no provider documentation for clinical inertia, 3) false non-concordance: lack of concordance when HbA1c greater than or equal to 7

percent with documentation for clinical inertia, 4) refused therapy: therapy intensification recommended, but patient refused. Clinical impacts of false non-concordance defined as 1) positive: HbA1c last recorded less than HbA1c during initial visit, 2) negative: HbA1c last recorded greater than or equal to HbA1c during initial visit.

Results: Of the 116 study cases who visited the MMP-EDC during the study window, clinical inertia was found to occur approximately 34 percent of the time (n equals 40). The baseline characteristics of our study cases were: mean age 62 years, 45 percent male, 93 percent white or Caucasian, mean HbA1c 8.4 percent, mean BMI 39, mean SCr in mg/dL 1.3. After exploring the contributing factors for clinical inertia, 21 patients (53 percent) were associated with concordance, 4 patients (10 percent) were associated with true non-concordance, 12 patients (30 percent) were associated with false non-concordance, and 3 patients (8 percent) refused therapy. Negative clinical impacts of false non-concordance occurred in 4 patients (33 percent) and positive clinical impacts of false non-concordance occurred in 8 patients (67 percent).

Conclusion: 67 percent of MMP-EDC patients with providers documenting contributing factors for clinical inertia were associated with positive clinical impacts. After further exploration of the contributing factors that influenced nonadherence to ADA guidelines was the documented downward trend of the HbA1c. This suggests that the provider's therapeutic decision to not apply specific guideline recommendations is influenced by factors other than the HbA1c value alone, such as the provider-patient relationship, clinical judgment and experience. Future studies in multiple practice settings which include a larger population size may help clarify the clinical implications of false non-adherence.

Poster Title: Alirocumab: new drug review and cost-minimization analysis

Primary Author: Emily Reed, University of New England, College of Pharmacy, Maine; **Email:** ereed@une.edu

Additional Author (s):
Kaitlyn Bernard
Morgan Harper
Chantale Maloney
Leslie Ochs

Purpose: Alirocumab is the first cholesterol-lowering agent approved in a new class of drugs known as proprotein convertase subtilisin kexin type 9 (PCSK9) inhibitors. This new drug is indicated as add-on therapy for adults with primary heterozygous familial hypercholesterolemia (HeFH) or clinical atherosclerotic cardiovascular disease (ASCVD), and in patients who require additional LDL-cholesterol lowering, with diet control and maximally tolerated statin therapy. The objective of this new drug review was to define the role of alirocumab in current therapy and its drug-specific characteristics, including efficacy, safety, and tolerability. A cost-minimization analysis was also performed.

Methods: Phase III, randomized, double-blinded, placebo-controlled, and active comparator clinical trials and product labeling were the primary literature sources used for this review. Databases searched included: MEDLINE-PubMed, Cochrane Database of Systematic Reviews, and Embase. Current clinical guidelines from the American Diabetes Association (ADA) and American Heart Association (AHA) were considered. Additionally, clinical information was gathered from the US Food and Drug Administration (FDA), Lexicomp, and the Academy of Managed Care Pharmacy (AMCP) dossier was evaluated. A cost-minimization analysis was performed comparing similar agents to aid in a formulary recommendation. Publicly available data sources were used for drug costs.

Results: Alirocumab, a PCSK9 inhibitor, is a humanized monoclonal antibody, given every two weeks by subcutaneous injection. This new drug is indicated as adjunctive therapy to diet and maximally tolerated statin therapy for patients with primary HeFH or ASCVD. Currently, there

are no head-to-head clinical studies with alirocumab and evolocumab, another PCSK9 inhibitor. In a meta-analysis of 25 randomized control trials, alirocumab showed an additional 36-59 percent LDL reduction when combined with maximally tolerated statins and was associated with an overall reduction in LDL by 52.6 percent versus placebo and 29.9 percent versus ezetimibe when combined with a statin. This drug is well tolerated with common adverse effects, including nasopharyngitis, diarrhea, injection site reactions, and influenza. Cost-minimization analysis rankings of medications used to lower LDL from the least to most cost-effective include: atorvastatin, rosuvastatin, Lipitor, evolocumab, and alirocumab.

Conclusion: Alirocumab, as an adjunct therapy to statins, effectively lowers LDL levels in patients with primary HeFH and ASCVD. Due to its high cost and limited long-term safety and efficacy, alirocumab was recommended as non-formulary with additional prior authorization criteria to ensure patients had an adequate response to more cost-effective alternatives prior to using alirocumab.

Poster Title: Warfarin Effectiveness in Patients Receiving Enteral Feeding

Primary Author: Dao Tran, College of Pharmacy

University of Minnesota, Minnesota; **Email:** tranx777@umn.edu

Additional Author (s):
Scott Seaburg

Purpose: When a patient needs to take warfarin and to be concurrently supported with enteral feeding, the responsible clinician needs to carefully manage the patient. A few case reports and in vitro studies have shown that warfarin use while on enteral feeding can result in 'warfarin resistance' which is better labeled 'warfarin malabsorption'. We conducted a literature review to document the influence of enteral feeding upon warfarin effectiveness (achieving target INR and time in therapeutic range). The results may be used to develop guidelines for management of patients needing anticoagulation and enteral feeding simultaneously while in the hospital.

Methods: The literature was reviewed for case reports, in vivo and in vitro studies, guidelines or protocols related to warfarin and tube feeding. Thirty-six references and 4 sets of guidelines were found and reviewed. These sources were reviewed to answer the following questions: (1) "When a patient is stabilized on warfarin, what is the change (i.e., amount and timing) in INR experienced when enteral feeding is started or stopped?"; and (2) "When a hospitalized patient is on warfarin, what adjustments to the enteral feeding process can keep the INR in the therapeutic range? Each case of a patient, or in vitro study, was recorded along with the circumstances related to warfarin and enteral feeding use. This literature search looked for specific 'warfarin change events' to determine if they made a meaningful difference in the patient's response to warfarin such as a change in INR level or time in therapeutic range (TTR). Among the 'Warfarin Change Events' identified were: (1) A change in the dosage regimen of warfarin; (2) Initiation of the use of warfarin in a patient receiving enteral feeding; (3) Initiation or discontinuation of the use of enteral feeding in a patient receiving warfarin; or (4) A change in the procedure for administering enteral feeding (e.g., holding feeding before and after the warfarin; change in enteral feeding formula; change in feeding tube, etc.).

Results: Daily monitoring of INR should be done to manage warfarin dosing and to maximize time in therapeutic range (TTR) with a typical target INR range of 2.0 to 3.0. Impaired bioavailability of warfarin has been attributed to various factors related to enteral feeding including: (1) presence of vitamin K in enteral products; (2) binding of warfarin to proteins in nutritional products; (3) binding of warfarin to feeding tubes; and (4) albuminuria which can reduce warfarin effect due to more binding to serum albumin. When possible a warfarin patient's dietary vitamin K intake should be known and held constant. Several sources recommended that enteral feeding should be stopped 1 hour before and after administration of warfarin. Since warfarin binding to feeding tubes may reduce warfarin concentration 23% to 38%, several sources recommended flushing of feeding tubes with water before and after warfarin administration. Increases in serum albumin concentration due to enteral feeding, or for any reason, may lead to reduced therapeutic effect from warfarin. Although warfarin is rapidly absorbed (peak about 4 hours) and widely distributed throughout the body in 6 to 12 hours, the therapeutic effect of changes in warfarin level may take three or more days to develop.

Conclusion: The literature documented several circumstances in which a patient on warfarin and enteral feeding may have impaired warfarin bioavailability. Studies in the literature have demonstrated the effects of various factors that influence warfarin bioavailability. Literature reports provide practical details for optimal warfarin administration through enteral feeding tubes including tube type and size, enteral access sites, drug administration techniques, and timing of enteral feeding and drug administration. The information and results from this review provide a means to help clinicians identify and carefully manage factors that may influence warfarin effectiveness, such as INR and TTR, in patients concurrently using tube feeding.

Submission Category: Ambulatory Care

Poster Title: Comparing first and third-year family medicine residents' perceptions of collaboration with pharmacists at the Duluth Family Medicine Clinic

Primary Author: Evelyn Grafton, University of Minnesota, Minnesota; **Email:** graft010@d.umn.edu

Additional Author (s):
Keri Hager

Purpose: The purpose of this project is to understand the state of family medicine resident and pharmacist collaboration from the perspective of the family medicine residents at the Duluth Family Medicine Clinic located in Duluth, MN. The goal of this research is to optimize medicine and pharmacy collaboration in the ambulatory setting. This will be used to expand collaborative opportunities in the future.

Methods: Sixty-minute focus groups were separately conducted by the primary investigator, with groups of first-year and third-year family medicine residents. The audio for the focus groups were recorded, with the participants remaining anonymous to allow them to give feedback freely. The residents were asked questions related to the role of a pharmacist and their interprofessional interactions at the clinic. Audio from the focus groups was recorded and transcribed verbatim. Content analysis of the transcripts was conducted using the classic analysis strategy by two investigators. The transcripts were coded for common themes using a constant comparison-like approach to analyze what focus group participants said. The themes were then compared between the first-year and third-year resident focus groups.

Results: The focus group conducted on January 8th 2015 consisted of six of nine third-year family medicine residents in the program. The focus group on January 15th 2015 included seven of the eight first-year family medicine residents. The themes of accessibility, limited time, using pharmacists to answer questions, and education from pharmacists were common to both focus groups. There were also multiple themes from the first year and third year groups that were unique to each group. The themes unique to the first-year group were patient-centered care, using pharmacists for double check in the hospital, pharmacists helping with complicated patients and polypharmacy, pharmacists helping with insurance, and pharmacists being

knowledgable on immunizations. Themes unique to the third-year group were patients being honest with the pharmacist, pharmacists being helpful for medication reconciliation, having pharmacists make recommendations, relying on pharmacists to adjust doses, having more contact with hospital pharmacists than community, appreciating pharmacist input, and increased collaboration with familiar people.

Conclusion: It appeared that first-year residents used pharmacists more for a safety net and an information resource, while third-year residents collaborated with pharmacists for more clinical duties. Some examples of this mentioned by third-year residents were medication reconciliation and dose adjustments. Third-year residents had a common theme of appreciation for pharmacists, showing the positive relationship they developed at the clinic.

Additional Author (s):
Hannah Chang
Danielle MacDonald
Keri Hager

Purpose: The purpose of this study was to determine the number of drug therapy problems (DTP) identified and resolved on the same day as the Medication Therapy Management (MTM) appointments conducted at a family medicine residency program clinic.

Methods: This was a retrospective chart review conducted at the Duluth Family Medicine Clinic (DFMC) analyzing documentation of 631 MTM visits retrieved from the electronic health record system between August 1st, 2012 and February 28th, 2015. This study included all patients who were referred by medical residents at DFMC to receive MTM services. The study only excluded patients who weren't under the care of medical residents. Clinical pharmacists and pharmacy residents performed the MTM visits.

Results: Of the 631 MTM visits, the mean (SD) age was 53.76 (15.68) years old with a mean number of conditions of 5.7 (2.49). Patients were taking a mean of 11.9 (5.78) medications. The mean number of drug therapy problems identified was 4.24 (2.10). The mean drug therapy problems resolved the same day of the visit was 2.08 (1.66). The mean MTM visit time was 31.14 (9.44) minutes.

Conclusion: Patients who received MTM services at DFMC had 50% of their DTPs resolved on the same day of their visit. One area of potential future research is to categorize the DTPs and identify the most frequent categories of DTPs. This information is needed to design global interventions such as continuing education to providers to prevent DTPs from occurring.

Poster Title: Does weight matter in the dosing of therapeutic biologics?

Primary Author: Ya-Feng Wen, University of Minnesota, Duluth, Minnesota; **Email:** wenxx164@d.umn.edu

Additional Author (s):
Yow-Ming Wang

Purpose: The general perception is that biologics more often adopt body-size-dependent dosing regimen in comparison to the weight-independent (fixed)-dose regimen which is common for small molecule drugs. The body-size-dependent dosing approach stems from the hypothesis that it can minimize the pharmacokinetic (PK) variability in patients. This study aims to verify the hypothesis/perception by answering the following questions:
1) What is the proportion of FDA approved biologics using fixed versus body-size-based dosing approach?
2) Does the selected dosing regimen follow the allometric principle for PK model?
3) Is the PK variability smaller when the dosing approach follows the allometric principle?

Methods: Therapeutic biologics is a booming area with 118 products approved by U.S. Food & Drug Administration (FDA) as of August 2016. We reviewed FDA approved labels and clinical pharmacology review documents for 66 biologics approved during 2005-2016 to identify the dosing approaches, PK models, and the inter–individual variability (IIV) for area under the curve (AUC) and concentration data. An additional 16 products approved before 2005 were included in this study based on literature review. The effect of body weight on clearance (CL) is routinely evaluated in population PK model using the allometric function with an exponent of θ_{BW_CL}. Current literature suggests that when θ_{BW_CL} is < 0.32, fixed dosing results in less IIV; whereas when θ_{BW_CL} is > 0.68, body-size-dependent approach is better in reducing IIV. The lower IIV in PK parameters is associated with a smaller deviation from the population average for subjects with extreme body weight values, i.e., extremely high or extremely low. If θ_{BW_CL} lies between 0.32 and 0.68, both dosing approaches perform similarly. We examined how many products have dosing regimens that follow such principle. For assessing IIV, the variability in AUC, measured as % coefficient of variation (%CV), was used

in the study and the difference in PK variability between products that follow the above principle and those products that do not was calculated by Mann-Whitney U Test.

Results: Of 82 therapeutic biologics, 37 (45.1%) are dosed using fixed-dose approach. The proportion of products using fixed-dose approach is similar between monoclonal antibodies (46.0%) and proteins (43.8%). Among body-size-dependent dosing approaches, a commonly used method is body weight (BW)-based dosing, i.e., mg/kg, followed by body surface area (BSA)-based dosing, i.e., mg/m2. In 58 biologics with available theta_BW_CL value, body weight is a significant covariate for clearance in 46 products. Among which, 3 (5.2%) products have theta_BW_CL < 0.32, 20 (34.5%) products have theta_BW_CL between 0.32 and 0.68, and 23 (39.6%) products have theta_BW_CL > 0.68. For the remaining 12 products, body weight has no effect on clearance and theta_BW_CL = 0. As expected, 93.3% of 15 biologics with theta_BW_CL less than 0.32 use fixed-dose approach. In contrast, only 60% of products with theta_BW_CL > 0.68 adopt body-size-dependent approach. In biologics with theta_BW_CL between 0.32 and 0.68, as anticipated, the difference in %CV for AUC between two dosing approaches was not statistically significant with smaller deviation in body-size-dependent dosing of 33.8% versus fixed-dose of 37.0% (p-value: 0.55). Unexpectedly, there was also no significantly difference in %CV for AUC between the two groups in biologics with theta_BW_CL greater than 0.68. (p-value: 0.83).

Conclusion: This analysis demonstrated that both fixed dose and body-size-dependent approach are commonly used in therapeutic biologics. While theta_BW_CL can serve as a tool for selecting the dosing strategy in first-in-human studies, the final recommended dose regimen is often influenced by other factors. Further research is needed to identify other important factors affecting the pharmacokinetics/pharmacodynamics and clinical response for therapeutic biologics.

Poster Title: Nuclear localization of G protein-coupled receptor kinase 5 in primary human cardiomyocytes and its interactions with nuclear proteins

Primary Author: Alyssa Nguyen, Roseman University of Health Sciences College of Pharmacy, Nevada; **Email:** anguyen7@student.roseman.edu

Additional Author (s):
Chad Colwell
Christopher So

Purpose: In this early report, we queried nuclear GRK5 expression in primary human cardiomyocytes and explored its ability to interact with and phosphorylate a number of nuclear proteins- nucleophosmin, nucleolin and nucleostemin.

Methods: The nuclear GRK5 localization was queried by immunofluorescence in primary human cardiomyocytes. Co-immunoprecipitations were performed to determine if GRK5 interacts with nucleophosmin in these cells. In vitro phosphorylation reactions were carried out to determine if GRK5 can phosphorylate nucleolin and nucleostemin

Results: We observed nuclear GRK5 localization in primary human cardiomyocytes. Co-immunoprecipitations between GRK5 and NPM1 was observed in nuclear extracts from human cardiomyocytes. In vitro phosphorylation reactions showed that GRK5 phosphorylates nucleolin and nucleostemin, demonstrating that they are new GRK5 substrates.

Conclusion: In this report, we showed that GRK5 is observed in the nucleus of primary human cardiomyocytes, recapitulating what was observed in other cardiomyocytes and cancer cell lines. In addition, we see also GRK5-NPM1 complexes in these cells, observed previously in cancer cells, as well as new GRK5-nuclear protein complexes. Collectively, this suggests that nuclear GRK5 could be functional in the nucleus to control a plethora of nuclear processes through protein-protein interactions.

Poster Title: Dexmedetomidine use in initially non-intubated children

Primary Author: Dhara Shah, Ernest Mario School of Pharmacy, New Jersey; **Email:** ds925@scarletmail.rutgers.edu

Additional Author (s):
Christine Robinson
Suzannah Kokotajlo
Ma Bernardita Gamallo

Purpose: Dexmedetomidine is approved in adults for sedation of initially intubated and mechanically ventilated patients during treatment in an intensive care setting and non-intubated patients prior to and/or during surgical and other procedures. Manufacturer labeling recommends to not exceed use beyond 24 hours. Safety of prolonged use has been reported in initially intubated pediatric and adult patients, but support is lacking for initially non-intubated patients during treatment in an intensive care setting. The purpose of this study is to evaluate the safety and effectiveness of dexmedetomidine use in initially non-intubated pediatric patients for non-procedural sedation.

Methods: The Atlantic Health System and Rutgers institutional review boards approved this retrospective chart review. Patients that were initially non-intubated, 21 years of age and younger, admitted at Goryeb Children's Hospital, and who received dexmedetomidine for non-procedural sedation between January 1, 2014 and December 31, 2015 were included in the study. The data that was collected included patient demographics such as admitting diagnosis, length of stay, type of respiratory support, and concomitant sedation and/or analgesia used. Dexmedetomidine indication, dose, and duration as well as occurrence and management of adverse effects (bradycardia and hypotension) was also recorded. Horizon Meds Manager was used as the source of study participants by creating a Clinical Drug Utilization Report. Information from Medical Records was used to identify potential participants which were verified through a chart review. The primary outcome was to evaluate the safety and effectiveness of dexmedetomidine use for prolonged non-procedural sedation in initially non-intubated pediatric patients. Secondary outcomes included the description of

dexmedetomidine use such as indication for sedation, dose, duration, adverse effects, and concomitant sedation and analgesic medications.

Results: A total of 47 initially non-intubated pediatric patients were included. The median length of stay was 5 days. The median age of patients was 2 years with the majority of the primary admitting diagnoses being pulmonary related (83 percent). The median starting dose was 0.3 mcg/kg/hour, with a median maximum dose of 0.7 mcg/kg/hour, and median infusion duration of 53 hours. No patients were given a loading dose. All were treated in the pediatric intensive care unit. The most frequent types of respiratory support used when dexmedetomidine was initiated were bilevel positive airway pressure (45 percent) and high-flow nasal cannula (28 percent). The indications for sedation were agitation (80 percent), irritability (13 percent), anxiety (4 percent), pain (4 percent), aggressiveness/combativeness (2 percent), and to minimize respiratory effects (2 percent). Bradycardia was noted in 4 percent, hypotension in 2 percent, and bradycardia and hypotension in 2 percent of patients. The adverse effects lasted 3-6 hours and were managed by holding the infusion or decreasing the rate. Majority of patients (62 percent) received zero concomitant sedatives/analgesics, while 28 percent received one, 4 percent received two, and 6 percent received three. Only 2 percent of patients required post-dexmedetomidine intubation.

Conclusion: Use of dexmedetomidine in initially non-intubated pediatric patients for non-procedural sedation was safe and effective. Adverse effects of bradycardia and/or hypotension occurred in only 8 percent of the patients and they were responsive when the dose of dexmedetomidine was held or rate of infusion was reduced. Additionally, a majority of patients did not require concomitant sedatives and/or analgesics. Dexmedetomidine may be considered for sedation in pediatric patients treated in an intensive care setting who are initially non-intubated.

Submission Type: Case Report

Session-Board Number: 2-188

Poster Title: Outpatient management of diabetic gastroparesis with orally-administered erythromycin in a patient with comorbid psychiatric disorders: A case report

Primary Author: Jeffrey Yang, Ernest Mario School of Pharmacy, New Jersey; **Email:** jyanggx@gmail.com

Additional Author (s):
Caitlin McCarthy

Purpose: Diabetic gastroparesis (DGP) is a frequent and clinically important complication of diabetes mellitus (DM). It is characterized by delayed gastric emptying without mechanical obstruction which can lead to associated cardinal symptoms, such as nausea, vomiting, early satiety, bloating, and abdominal pain. The first-line management of DGP includes restoration of fluids and electrolytes, nutritional support, and optimization of glycemic control. Prokinetic agents, alone or in combination with antiemetics, may be used for symptomatic management. Of available prokinetic agents, metoclopramide is the only agent that has been approved by the U.S. Food and Drug Administration for the treatment of DGP. However, metoclopramide use may not be appropriate for all patient populations, such as those predisposed to psychiatric conditions. Drowsiness, fatigue, lassitude, and restlessness occur in approximately 10% of patients on the mostly commonly prescribed dose. More serious psychiatric complications have also been reported, including agitation, anxiety, insomnia, mental depression, suicidal ideation, and hallucinations. In cases when metoclopramide is not appropriate, alternative prokinetic agents may be considered, including domperidone, cisapride, and erythromycin; however, data to support use of alternative agents is limited. Domperidone is currently unavailable in the United States, and cisapride use is associated with cardiac arrhythmias and death. As domperidone is not available for use and the risk of using cisapride appears to outweigh the benefit, erythromycin is likely the most appropriate option for use in patients who cannot tolerate metoclopramide. Yet, evidence supporting the effectiveness of erythromycin is limited to small-scale clinical trials and case reports. This case report aims to illustrate the clinical dilemma of using prokinetic agents to manage a patient with comorbid DGP and psychiatric illnesses. A 40-year-old female with a 15-year history of DM and comorbid bipolar and anxiety disorders presented to her primary care provider (PCP) with complaints of stomach cramps, lack of appetite, and progressively worsening nausea and vomiting. The patient was referred to

a gastroenterologist who diagnosed the patient with DGP. Treatment was not initiated. As symptoms persisted, the patient returned for a follow up visit with her PCP. At the time, her glycosylated hemoglobin was 6.1%, indicating adequate glycemic control. Results from her metabolic panel were within normal limits. Her gastroparesis cardinal symptom index (GCSI) was calculated to be 28 out of a possible 45, indicating the presence of severe, symptomatic DGP. Due to the risk of exacerbating psychiatric symptoms, metoclopramide was not recommended. Alternative therapy with oral erythromycin was initiated at a dose of 250 milligrams three times daily with an intended duration of therapy of 4 weeks, which is consistent with the dosing found in the literature. An over-the-counter nutritional supplement was also prescribed. The patient completed the full 4-week trial of erythromycin therapy and claimed to be adherent to the regimen. After the trial was completed, the GCSI was recalculated to be 38 out of 45, indicating worsening of the symptoms of DGP. As this case report suggests, pharmacotherapy options for the treatment of DGP are limited. While results from small clinical trials and case reports indicate that erythromycin may be a safe and effective alternative to metoclopramide, results from our case report did not support such a claim. Additional, well-controlled studies are warranted to confirm that erythromycin is a safe and efficacious medication to be used for the treatment of DGP in patient who cannot tolerate metoclopramide.

Poster Title: Loss of Weight with Phentermine and Topiramate (LOW PhAT): A Retrospective Analysis

Primary Author: Derek Chiu, Ernest Mario School of Pharmacy, New Jersey; **Email:** dchiu2688@gmail.com

Additional Author (s):
See Gin Lee
Thom Nguyen

Purpose: One third of the adult population is affected by obesity in the United States. If weight loss is not achieved after lifestyle modification, pharmacotherapy can be initiated. Phentermine has been approved for short term management of weight loss but can be used off label for chronic management. Topiramate monotherapy has also been effectively used off label for weight reduction. However, there is limited information regarding the efficacy of long term use of these medications. The purpose of this study is to determine the average percent weight loss on short term versus long-term therapy with phentermine or topiramate.

Methods: The institutional review board approved this retrospective study that was conducted at two family medicine practice sites. Patients included in the study were men and women greater than 18 years of age who were taking phentermine or topiramate between January 2010 and August 2016. Individuals who failed to have their weight recorded in the beginning of therapy, at 12 weeks, and end of therapy were excluded as well as patients who failed to fill their phentermine prescriptions according to the New Jersey Prescription Monitoring Program. Patients on combination phentermine and topiramate were also excluded. A data collection sheet was created to record patient demographics, weight, treatment, and change in weight. The primary outcome was to evaluate the average percent body weight loss of phentermine or topiramate on short term (less than 12 weeks) versus long term (more than 12 weeks) therapy. The secondary outcome was to evaluate the percent of patients who achieved 5% weight loss from baseline at 12 weeks for phentermine or topiramate. Descriptive statistics was used to analyze the data.

Results: After patients were screened, 23 patients were included in the phentermine group and 53 patients were included in the topiramate group. The patient demographics were mostly female, and white with an average age of 46.4 years for phentermine and 45.3 years for topiramate. The average treatment duration was 48.5 weeks and 38.8 weeks. For the primary endpoints, the phentermine group experienced more weight loss on short term treatment at 4% than topiramate group at 1.23%. For long term therapy, the phentermine group lost 3.45% and topiramate group lost 1.79%. Twelve (50%) patients on phentermine and ten (18.9%) patients on topiramate were able to meet a 5% weight loss goal at 12 weeks of treatment.

Conclusion: The findings from this study indicate that both phentermine and topiramate can induce weight loss but few patients continued to lose weight after 12 weeks of treatment. These results support current recommendations of short term utilization. Therefore, patients may experience the most benefit with short term weight loss treatment. Cessation of these medications after 12 weeks may be encouraged to limit the adverse effects especially if there is not a continued significant weight loss.

Submission Type: Evaluative Study

Session-Board Number: 2-190

Poster Title: Evaluation of prescriber adherence to methadone use policies in a community hospital

Primary Author: Kevin Lai, Ernest Mario School of Pharmacy, New Jersey; **Email:** kevinhockylai@gmail.com

Additional Author (s):
Daniel Abazia

Purpose: Most hospitals do not possess a methadone detoxification license and thus cannot initiate methadone detoxification or maintenance therapy. Methadone can be prescribed for the purposes of pain control, continuation of a patient enrolled in an opiate maintenance program admitted for non-addiction related medical treatment, or to manage acute withdrawal symptoms if they interfere with medical treatment. Use of methadone in this manner must follow a specific protocol to be in compliance with hospital policy. The purpose of this study was to evaluate prescriber adherence to our institution's methadone maintenance policy.

Methods: The health-system's institutional review board approved this retrospective chart review. The health system's clinical information system was utilized to identify male and female inpatients 18 years of age or older who received oral methadone admitted between March 1, 2015 to February 29, 2016. Information collected included (1) demographic information (patient age, gender, actual body weight); (2) patient medical information (urine drug screen performed/result, patient enrollment in methadone maintenance program/program contact, therapeutic use of methadone); (3) opioid withdrawal management (initial withdrawal symptoms, initial dose of methadone, appropriateness of initial dose, subsequent doses administered, mean methadone dose in 24 hour period, prescribing physician specialty, hospital unit/floor of methadone administration, clonidine use, and length of stay). Descriptive statistics were computed for the total sample. Variables examined include demographic characteristics and available clinical outcomes. For continuous variables, means, medians, and standard deviations were computed. For categorical variables, percentages will be reported.

Results: Eighty five patients were identified and 84 patients who received oral methadone were included in our analysis. Seventy five percent of patients (n = 63) were enrolled in a methadone

maintenance program and contact was successfully made with 95.2 percent of methadone clinics. Approximately 11 percent of initial methadone doses were inappropriate for management of withdrawal symptoms and 50 percent of doses were lacking withdrawal symptom documentation. Only 39.3 percent of initial methadone doses were in compliance with the hospital's methadone maintenance policy. Methadone use exceeded 40 mg a day in 10.7 percent of patients receiving methadone for management of withdrawal symptoms.

Conclusion: Prescriber adherence to our institution's methadone maintenance policy is low. Specific areas of deficiency to our policy are a lack of documentation of opiate withdrawal symptoms and appropriateness of initial and subsequent methadone doses. An alarming percentage of doses were inappropriate for withdrawal symptoms documented or exceeded hospital policy for maximum daily methadone dose. Implementation of a standardized and validated opiate withdrawal scale may be helpful in improving adherence to the institution's methadone maintenance policy.

Poster Title: Call to action on opioid addiction: gap analysis of New Jersey naloxone pricing and access

Primary Author: Yumi Yi, Ernest Mario School of Pharmacy, New Jersey; **Email:** yy227@scarletmail.rutgers.edu

Additional Author (s):
Samantha Paone
Nicole Daukshus
Paul Weber
Bruce Rector

Purpose: On February 2, 2016, President Obama proposed a 1 billion dollar budget to increase funding for drug abuse, especially those related to heroin and prescription opioids. This would allow increased access to treatment, particularly the emergency life-saving drug naloxone. With the significant rise in drug overdoses in the past few years, naloxone prices have risen exponentially. The purpose of this study was to analyze the prices of the different administration forms of naloxone and to determine its availability in the top 5 counties in New Jersey (NJ) associated with the highest opioid and heroin use.

Methods: The NJ Division of Mental Health and Addiction Services was contacted to find the top 5 NJ counties with the highest heroin and opioid admission rates. Towns with the highest admission rates within their respective counties were chosen to be studied. Pharmacies (independent and chain pharmacies) in each of these towns were identified and asked about the availability and cash pricing of 3 products of naloxone, including the Narcan nasal spray (4 mg), injectable naloxone (0.4 mg/mL), as well as the Evzio naloxone auto-injector (0.4 mg). The pharmacist was queried through a standardized method of data collection which captured each naloxone product and enabled the interviewer to inquire about the cash price of the specific strength and if the specific product was currently in stock.

Results: In Toms River Township (Ocean County), 2 of 10 pharmacies had naloxone products available. Prices ranged from 19 to 5625 dollars, depending on administration form. In Middletown Township (Monmouth County), 0 of 8 pharmacies had naloxone products

available. Prices ranged from 35 to 4000 dollars depending on administration form. In Newark City (Essex County), 1 of 11 pharmacies had naloxone products available. Prices ranged from 19 to 5600 dollars depending on administration form. In Atlantic City (Atlantic County), 0 of 5 pharmacies had naloxone products available. Prices ranged from 28 to 5000 dollars depending on administration form. In Camden City (Camden County), 1 of 10 pharmacies had naloxone products available. Prices ranged from 26 to 4700 dollars depending on administration form. The most expensive administration form was found to be Evzio naloxone auto-injector. The least expensive administration form was found to be injectable naloxone. There was only 1 independent pharmacy and 3 chain pharmacies that had naloxone available.

Conclusion: Despite the increase in drug overdoses in the past few years, naloxone access remains scarce. Brand products of naloxone (Narcan and Evzio) were more expensive than the generic naloxone injection. Only 4 of 45 pharmacies had naloxone readily available. Laws were passed to increase naloxone access, but changes have not yet reached communities with high substance abuse admission rates. Increasing availability of naloxone in local pharmacies is an important public health option that could permit patients and caregivers to take timely and necessary actions to reduce opioid-related adverse events including most tragically, a patient's death.

Poster Title: Drug-induced thrombocytopenia after consumption of tonic water

Primary Author: Jeffrey Tagle, Ernest Mario School of Pharmacy, New Jersey; **Email:** jeffreyrftagle@gmail.com

Additional Author (s):
Lauren Igneri

Purpose: Drug-induced thrombocytopenia (DITP) is a diagnosis of exclusion since other causes of thrombocytopenia must first be ruled out. DITP can lead to severe consequences, including spontaneous bleeding or defects in clotting. We describe a 49-year-old female who woke up with what was described as a "blood blister" on her lip. In the emergency department (ED), the patient stated she experienced bleeding from her tongue, inner cheek, and nose, reported heavier than usual menstrual flow, and noted red spots on her lower extremities which prompted her to seek medical care. The patient reported drinking two glasses of gin and tonic at dinner the previous night. Physical exam findings include hemorrhagic bullae on the inner right cheek, a hemorrhagic lesion on her lip, dried blood in the nares, mildly dry mucous membranes, and petechiae on her lower and upper extremities, abdominal wall, and chest. She was found to have a platelet count of 3000 cells per microliter. The patient had a documented quinine allergy in which she experienced bleeding and thrombocytopenia in the past. Past medical history includes type 1 diabetes mellitus managed with an insulin pump. Based on the patient's history of quinine-induced thrombocytopenia and the inadvertent consumption of tonic water, the diagnosis of drug-induced thrombocytopenia was made. The patient received methylprednisolone 60 mg IV for one dose, intravenous immunoglobulin 48 g (0.5 mg/kg) for one dose, and a transfusion of platelets in the emergency department. Methylprednisolone 60 mg every 6 hours was given until the patient was discharged. Additionally, the patient received aminocaproic acid 50 mg every 8 hours for menorrhagia. Her platelet count improved to 40,000 cells per microliter on hospital day 3 and 56,000 cells per microliter on hospital day 5. Signs and symptoms of bleeding resolved by discharge on hospital day 5. Recommendations for the treatment of DITP include discontinuation of the drug and, if severe, a transfusion of platelets. Since other causes of thrombocytopenia are being ruled out on presentation, treatment for primary immune thrombocytopenia which includes corticosteroids (dexamethasone 40mg by mouth or prednisone 1mg/kg by mouth) and intravenous immune globulin 1g/kg or plasma

exchange, may also be considered initially. There is no evidence to support the continued use of these treatments in patients with confirmed DITP. In this case, the platelet transfusion, methylprednisolone, and immune globulin were appropriate upon presentation, but the immune globulin dose was lower than recommended (0.5 mg/kg vs. 1mg/kg). The continued use of methylprednisolone was also inappropriate and resulted in elevated blood glucose levels in a diabetic patient. Applying the Naranjo adverse drug reaction probability scale, a score of 8 was obtained, which indicates a probable association between the patient's consumption of tonic water and thrombocytopenia. This case highlights the importance for healthcare providers to not only document an allergy to quinine in the medical record, but to also counsel the patient on medications and foods that contain quinine in order to prevent future episodes of DITP.

Poster Title: Evaluation of opioid analgesia for pain management in hospitalized hemodialysis–dependent patients

Primary Author: Cassandra Leo, Ernest Mario School of Pharmacy, New Jersey; **Email:** cassandraleo93@gmail.com

Additional Author (s):
Daniel Abazia
Caroline Steward

Purpose: Patients with end-stage renal disease (ESRD) who are hemodialysis-dependent have a high symptom burden. Over 50 percent of ESRD patients report suffering from moderate to severe pain. Studies confirm the accumulation of potentially harmful metabolites of opioids such as morphine, hydromorphone, and oxycodone in patients with renal failure. The World Health Organization (WHO)-analgesic ladder has been modified for patients with renal failure; however, there are no well-established guidelines for treatment of pain in ESRD patients. Our objective was to assess the appropriateness of opioids analgesia in hospitalized hemodialysis-dependent patients and to evaluate the prescribing patterns of non-opioid analgesics.

Methods: After receiving institutional review board approval, a query of the institution's Renal Dialysis Services clinical information system identified ESRD patients age 18 years or older who were hemodialysis-dependent and received at least one dose of analgesic medication during their admission to one of the two health-system's hospitals between January 1, 2014 and December 31, 2014. A retrospective chart review was performed and the following data was extracted: age, gender, ethnicity, comorbid conditions, opioid regimen(s) ordered, opioid dose(s) administered, concomitant non-opioid or adjuvant medication(s) regimens ordered and administered, pain levels (numeric scale), pain quality and description, vital signs, comprehensive metabolic panel lab results, and any reported adverse events. Numeric pain scores reported by the patient prior to analgesic regimen administration were compared to numeric pain scores reported by the patient following analgesic administration.

Results: Fifty-three patients encompassing 110 total admissions met inclusion criteria. Patient comorbidities included diabetes mellitus (48.1percent), depression or anxiety (15.4 percent),

and peripheral neuropathy (3.8 percent). Almost half of patient admissions (N=47; 44 percent) included only one analgesic medication order. The most commonly ordered analgesic medication was acetaminophen (48.2 percent) followed closely by morphine (44.5 percent), hydromorphone (43.6 percent), and the combination of oxycodone-acetaminophen (40.9 percent). Mean pain scores before administration were 7.8 and 7 for opioid and non-opioid medications, respectively. Patients receiving opioid analgesics had a mean pain score reduction of 5.75 while those receiving non-opioid analgesics had a mean pain score reduction of 5.25. Of 996 total medication orders, 55 orders (5.5 percent) specified a pain scale for administration, and 119 doses (11.9 percent) were given to patients whose reported pain scale was outside the specified range of the order. The total milligram morphine equivalent (MME) administered per day was 39.8 mg, which is considered a low daily dose as per the Centers for Disease Control and Prevention.

Conclusion: Our investigation revealed that potentially unsafe analgesics are ordered in approximately half of our patient population. Due to the retrospective nature of the study, adverse effects were rarely recorded and could not be compared between analgesic medications. Based upon our data, further use of non-opioid analgesia should be considered in this population. Patient-reported pain scores remains the most readily available measure for evaluating medication effectiveness and must be routinely documented. Because of the previously published research and our own observation, reduction in the use of opioids for pain management in the inpatient hemodialysis-dependent population is recommended.

Submission Type: Descriptive Report

Session-Board Number: 2-194

Poster Title: Navigating the barriers: Expanding access to paliperidone palmitate

Primary Author: Saba Nikpour, Ernest Mario School of Pharmacy, New Jersey; **Email:** sabanikpour@gmail.com

Additional Author (s):
Diane Kim
Justin Lim
Jesse Chen
Megan Maroney

Purpose: Schizophrenia is a mental disorder characterized by relapse episodes of altered perception, socialization and volition. Of the patients relapsing for the first time, a significant number admit to medication non-adherence and relapse shortly thereafter suggesting continued non-adherence. Such schizophrenic episodes lead to high healthcare and socioeconomic costs. Long acting injectables, such as Invega Sustenna and Invega Trinza, thus provide patients with one-month and three-month dosing alternatives to reduce non-compliance, relapse and costs, though coverage barriers hinder access to these medications. This poster explores barriers to insurance coverage of Invega, and delineates paths through which to navigate these barriers.

Methods: Research of the commercial plans of Medicare, Medicaid and the top pharmacy benefit managers was conducted to compare market access to long acting injectable formulations of Invega Sustenna (paliperidone palmitate), Invega Trinza (paliperidone palmitate) and Risperdal Consta (risperidone). Specific emphasis was placed on the following factors which affect market access: 1) formulary placement, 2) prior authorization requirement and 3) co-pay or co-insurance requirement, if such information was available. Following investigation of these barriers to access, research was conducted to explore various programs that offer assistance with access to Invega Sustenna and Invega Trinza. Each program was evaluated on: 1) source of funding, 2) eligibility requirements and 3) program description. These insurance plans and assistance programs were described qualitatively and quantitatively based on evaluation criteria. The average wholesale price of Invega was used to quantify co-insurance amounts.

Results: The data suggests that insurance plans classify Risperdal Consta, Invega Sustenna and Invega Trinza as non-preferred, specialty tier, or not covered. Out of 4,400 commercial health plans, Invega Sustenna was classified by 24 percent, 68 percent and 8 percent of plans as preferred, non-preferred and not covered, respectively. Also, Invega Trinza was classified by 14 percent, 83 percent and 3 percent of plans as preferred, non-preferred and not covered, respectively. Specifically looking at non-preferred plans, co-insurance costs can reach as high as 25 to 30 percent for both commercial and Medicare Part D plans, translating to out-of-pocket costs between 110 to 788 dollars for Invega Sustenna and 657 to 2365 dollars for Invega Trinza. Multiple programs exist to assist patients with these payments, nearly half of which are provided by Johnson & Johnson. These programs include: Janssen Connect, Instant Savings Program, Inpatient Free Trial Program, Outpatient Sample Program, Johnson & Johnson Patience Assistance Foundation, Medicaid Coverage Assistance, Medicare Savings Programs, Medicare Part D Extra Help, Third Party Coupons, and Prior Authorization Appeals Assistance. Co-pays when using 8 out of 10 of the above pathways are between 0 to 50 dollars, and are more often than not free-of-charge.

Conclusion: While many insurance barriers hinder market access to long-acting injectable formulations of Invega Sustenna and Invega Trinza, there are many ways to navigate these barriers. Having a comprehensive understanding of both the access barriers as well as the programs that offer assistance in addressing these barriers puts to rest much concern over therapeutic costs. Thus, in selecting medication therapy for patients with schizophrenia moving forward, prescribers ought to place more emphasis on the value of therapeutic compliance.

Session-Board Number: 2-195

Poster Title: Potential risk of 1,3 dimethylamylamine in patients with bipolar disorder

Primary Author: Jesse Chen, Ernest Mario School of Pharmacy, New Jersey; **Email:** jessechen215@gmail.com

Additional Author (s):
Megan Maroney

Purpose: This patient case illustrates the probable risk of taking pre-workout supplements containing 1,3 dimethylamylamine (DMAA) in patients with psychotic disorders. DMAA is an amphetamine derivative that is commonly found in sport supplements and often used for its weight loss, performance enhancing and body building effects. DMAA was once approved as an inhaled nasal decongestant but there is no currently approved medical use since it was taken off the market in 1983. Common health risks associated with DMAA include elevated blood pressure and tightening of the chest.   DMAA has also been suspected to have a risk of exacerbating psychosis. Despite the adverse event profile, DMAA is still a main ingredient found in dietary supplements, against FDA recommendations, including the product marketed as Executioner®.   The described patient reported taking this pre-workout supplement before his workouts. The patient had a history of bipolar disorder and was previously treated with quetiapine. He was brought in by the police for bizarre behavior and put in restraints after punching a nurse. He reports compliance to his medications and no current illicit drug use. His toxicology screen was negative. He was admitted to the psychiatry department presenting with diminished need for sleep, excessive and pressured speech, and clear evidence of distractibility. During his first day, he was easily irritated and delusional, requiring haloperidol injections as needed. Initially, the patient did not attend group sessions, such as art therapy, and was disruptive. The patient was noted to respond to auditory hallucinations, suggesting psychotic features associated with his current manic episode. He was continued on quetiapine, but the titration process was restarted with a dose of 100 mg initially. The dose of quetiapine was increased daily until a maximum of 800 mg at bedtime. During treatment team meetings, it was suspected that his pre-workout supplement may have exacerbated his recent manic episode with psychotic features. He reported recently taking Executioner® because it helps him through his workouts. DMAA was the main ingredient suspected in the pre-workout to exacerbate his current psychotic symptoms. The patient's psychotic features improved

throughout his twelve days at the hospital, requiring less haloperidol each day. He was more cooperative, less intrusive, and no longer delusional. Upon discharge, the plan was to continue his antipsychotic medication and to stop taking his pre-workout supplement. As this patient case suggests, certain ingredients in pre-workout supplements, like DMAA, have the potential to exacerbate psychotic symptoms in patients with psychotic disorders. Although more research is needed to solidify this association, patients with psychotic disorders should be advised against certain pre-workout products that may contain DMAA.

Poster Title: Retrospective analysis of cefepime and meropenem associated seizures in the neurologic intensive care unit

Primary Author: Alexander Smith, Ernest Mario School of Pharmacy, New Jersey; **Email:** asmith93@comcast.net

Additional Author (s):
Alison Brophy

Purpose: Neurologic critical care patients are at high risk of infection due to their increased risk of central nervous system infection and frequent reliance on life-supporting measures, such as ventilators. Antibiotic selection is driven by the drug's ability to penetrate the blood brain barrier, favoring the use of cefepime and meropenem. However, cefepime and meropenem have been associated with a rare, but serious risk of seizure. The purpose of this study is to evaluate if cefepime or meropenem is associated with a higher risk of seizure in a neuro-critical care population.

Methods: The institutional review board approved this retrospective chart review. Subjects over the age of 18 were enrolled if they were admitted to the intensive care unit for a neurologic diagnosis and received at least one dose of cefepime or meropenem. Patients who were actively being treated for seizure or experienced a seizure prior to receiving the first dose of the antibiotic were excluded from the study. Baseline patient characteristics collected include age, gender, creatinine clearance, admission diagnosis, and use of seizure prophylaxis. Baseline treatment factors include the choice of antibiotic, dose, indication, and duration of use. The primary outcome measure was the incidence of seizure while treated with cefepime or meropenem. Seizures were identified either by clinical documentation or by electroencephalogram. Secondary outcome measures include length of stay in the intensive care unit and change in mental status, as defined by change in Glasgow Coma Score, confusion, memory impairment, and speech difficulty. Seizure incidence was analyzed using the Fischer Exact test. The Students t-test was used to analyze length of stay in the intensive care unit. Mental status changes (Glasgow Coma Score, confusion, memory, and speech) were analyzed using the Mann-Whitney test.

Results: Sixty-four patients met inclusion criteria and were enrolled in this study. The average age of the population was 59.6 years, and the mean creatinine clearance was 76.2 ml/min. Female patients accounted for 36 (56.3 percent) of the enrollees. Thirty-five patients received cefepime, and twenty-nine received meropenem. Three patients who received cefepime and no patients who received meropenem had a seizure, resulting in a non-significant difference (P=0.245). The average length of stay in the intensive care unit for cefepime and meropenem was 12.2 and 13.2 days respectively, which did not demonstrate statistical significance (P = 0.551). The change in Glasgow Coma Score did not demonstrate statistical significance (P=0.322). Change in confusion, memory, and speech also did not show statistical significance (P= 0.757; P=0.234; P=0.223 respectively).

Conclusion: Use of cefepime did not demonstrate a statistically significantly increased risk of seizure over meropenem in neuro-critical care patients. However, all of the identified seizures occurred in patients who received cefepime. Thus, a larger prospective study powered to detect a difference would be warranted to identify if there is a difference in seizure rates between cefepime and meropenem in a neuro-critical care population.

Submission Category: Geriatrics

Submission Type: Descriptive Report

Poster Title: Identifying Inappropriate Medication Usage in Geriatric Fall Risk Patients via an Interdisciplinary Communication Tool

Primary Author: Smita Jaggernauth, Ernest Mario School of Pharmacy, New Jersey; **Email:** smita.jaggernauth@rutgers.edu

Additional Author (s):
Katie Militello

Purpose: Accidental falls occur frequently in older adults and are associated with considerable morbidity and mortality. Some of the most prominent risk factors for falling include postural instability, a history of falls, a Morse fall score of > 45, and the use of ≥ 3 medications implicated in causing falls. These medications have side effects which predispose patients to falls, such as orthostatic hypotension from certain antihypertensives and sedation from opioids and psychotropic drugs. The purpose of this study was to evaluate the inappropriate use of these medications in geriatric inpatients via an interdisciplinary communication form.

Methods: A brief survey was first disseminated amongst nurses, pharmacists, and physicians to gauge the extent to which each profession believed that interdisciplinary communication would help mitigate fall risk. Based on the survey results, a paper-based form was produced which identified patients at most risk of falling. The form was intended to be filled out by a multidisciplinary team of nurses, physicians, and pharmacists involved in each patient's care. The form was divided into sections allowing for nurses to document the patient's age, number of high fall risk medications, and Morse score; physicians to evaluate the patient's gait status; and pharmacists to flag potential therapeutic interventions. The form was trialed at two nursing units at 2 Meridian Health hospitals from July to August 2015. A medication utilization analysis was also performed on patients meeting inclusion criteria for potential fall risk. This was defined as patients older than 65 years of age and on ≥ 3 high fall risk criteria medications. High risk medications included medications from the Beers' Criteria and from other classes known to be associated with falls, including certain CNS agents (benzodiazepines, nonbenzodiazepine hypnotics, antipsychotics, anticonvulsants, antidepressants, opioids) and diuretics.

Results: In total, 16 out of 29 (55%) patients analyzed met inclusion criteria (older than 65 and on ≥ 3 high fall risk medications) for potential fall risk. Eleven out of 16 patients (69%) had Morse scores of ≥ 45, putting them at greatest risk of falling. A total of 50 high risk medications were identified from the 29 patients. The most frequent offenders were antidepressants and benzodiazepines, with each class individually making up 11 out of 50 (22%) of all medications and with both totaling 44% of all medications. The next most prevalent classes were opioids and diuretics, which were each separately observed in 7 out of 50 medications (14%). Anticonvulsants and nonbenzodiazepine hypnotics accounted for 10% of medications. Antipsychotics were recorded the least frequently, at a rate of 8%. From these medications, there was a total of 16 therapeutic interventions identified by pharmacists. Additionally, results from an interdisciplinary communication survey found that out of 58 healthcare providers interviewed, 76% of nurses, 100% of pharmacists, and 69% of physicians agreed that increased interdisciplinary communication would be beneficial in preventing falls.

Conclusion: As demonstrated by the survey results, a large majority of healthcare professionals believe that greater interdisciplinary communication is an important consideration to help mitigate geriatric inpatient fall risk. The results from the medication analysis demonstrated that many high risk patients may be inappropriately taking medications which further predispose them to falling. Future measures to curb the use of multiple high risk agents may be facilitated by communication forms such as the one trialed, which can help identify these patients prior to a fall incident.

Poster Title: Evaluation of an oral vitamin D supplementation protocol in a hospital-based hemodialysis unit

Primary Author: Jamie John, Ernest Mario School of Pharmacy - Rutgers University, New Jersey; **Email:** jsj58@scarletmail.rutgers.edu

Additional Author (s):
Daniel Abazia
Caroline Steward

Purpose: Recent evidence surrounding extra-renal 1-alpha hydroxylase and the pleiotropic effects of vitamin D has led to a discussion on the role of nutritional vitamin D supplementation in patients undergoing maintenance hemodialysis (MHD). While the 2009 Kidney Disease Improving Global Outcomes (KDIGO) clinical guidelines recommend correcting 25(OH)D levels less than 30 ng/mL for patients on MHD, it not does provide a specific treatment protocol. The primary objective of this study is to evaluate the proportion of outpatients achieving optimal 25(OH)D levels of greater than or equal to 30 ng/mL according to the vitamin D supplementation protocol in a hospital-based hemodialysis unit.

Methods: A retrospective analysis was conducted using the dialysis service electronic clinical information system to identify patients undergoing MHD with a 25(OH)D level less than 30 ng/mL from March 1, 2015 to June 1, 2016. Patients were excluded from the study if the corrected calcium level was greater than 10.2 mg/dL and PTH greater than 600 pg/mL. De-identified data was collected from the institution's clinical information system and electronic health information management platform. Data collected included: demographic information (age, gender, weight), baseline laboratory values (corrected calcium, phosphorus, PTH, albumin), active vitamin D analog administration, MHD treatment schedule, ergocalciferol administration, and follow-up 25(OH)D levels. The primary outcome measure was first 25(OH)D follow-up level greater than or equal to 30 ng/mL. Secondary outcomes included adherence to protocol, 25(OH)D level greater than or equal to 30 ng/mL within 6 months of first level taken (second follow-up), initiation of subsequent regimens for 25(OH)D levels less than 30 ng/mL, and third follow-up 25(OH)D level greater than or equal to 30 ng/mL.

Results: A total of 74 patients were included in this study. The overall average first follow up 25(OH)D level was 32.27 ng/mL, where only 32 patients (43.24 percent) were able to reach goal. Approximately 46 percent of patients received the appropriate ergocalciferol regimen according to baseline 25(OH)D level. Among these patients, 15 patients (44.12 percent) achieved a 25(OH)D level greater than or equal to 30 ng/mL. Within six months of treatment, 62 patients had a second 25(OH)D level drawn. Among these patients, 7 patients (11.29 percent) achieved a 25(OH)D level greater than or equal to 30 ng/mL, at an average of 21.44 ng/mL. A second vitamin D supplementation regimen was initiated in 48 patients and 11 of these patients had a third 25(OH)D level drawn. Among these patients, 2 patients (18.18 percent) achieved a 25(OH)D level greater than or equal to 30 ng/mL, at an average of 22.18 ng/mL.

Conclusion: Findings of this study indicate that a large proportion of patients within our hospital-based hemodialysis unit are unable to achieve a 25(OH)D level greater than or equal to 30 ng/mL. Improvements to our current vitamin D supplementation protocol may be beneficial in attaining target 25(OH)D levels. These may include improved adherence, more strict follow-up monitoring, and an extended duration of supplementation. Further studies may be beneficial in assessing the clinical outcomes of long-term vitamin D supplementation in MHD patients.

Submission Category: Pain Management

Submission Type: Evaluative Study

Session-Board Number: 2-199

Poster Title: Evaluation of pain management practices in patients with an opioid use disorder in a community teaching hospital

Primary Author: Stephen May, Ernest Mario School of Pharmacy - Rutgers University, New Jersey; **Email:** snm93@scarletmail.rutgers.edu

Additional Author (s):
Daniel Abazia

Purpose: Patients with an opioid use disorder (OUD) present a unique challenge in providing appropriate pain management within the acute care setting. Practitioners may be apprehensive that providing opioid analgesics propagates addiction and drug-seeking behavior of OUD patients. Clinical management is also complicated as OUD patients may be tolerant to standard doses of opioids. Prescribers seek an optimal, individualized regimen to provide adequate pain management while remaining vigilant that overreaches in therapy could negatively impact the patient. The purpose of this study was to help characterize pain management practice in OUD patients and identify areas of improvement within our institution.

Methods: A retrospective query by the hospital's Health Information Management (HIM) department was performed to identify patients with a primary or secondary discharge diagnosis of an opioid use disorder based upon the ICD-9 or 10 code between March 1, 2015 and February 29, 2016. Patients 18 years or older discharged from the institution with a primary or secondary ICD 9 and 10 discharge codes indicating an opioid use disorder (OUD) were included. De-identified data collected from the institution's clinical information system and electronic health information management platform included: (1) demographic information (patient age, gender, actual body weight, race/ethnicity, marital status, attending physician specialty, hospital unit/floor at discharge); (2) patient medical history (diagnosis of depression/anxiety, history of tobacco/alcohol/other substance use disorder, no. emergency department (ED) visits for pain, no. ED visits for overdose/withdrawal, history of pain syndrome); (3) current visit (pain diagnosis, numeric pain score at admission/discharge, average score, max score, and LOS); (4) pain management received (non-CII analgesic, short-acting CII analgesic, long-acting CII, average prescribed dose, average daily dose, total days of analgesic prescribed at discharge). Descriptive statistics were computed for the total sample. Variables examined included

demographic characteristics and available clinical outcomes. For continuous variables, means, medians, and standard deviations were computed. For categorical variables, percentages were reported.

Results: Data for 101 patient admissions were collected during the study period. Mean age was 48 years old, 67.33 percent of patients were male, and mean length of stay was 5.64 days. Using numeric pain score out of 10, mean pain score at admission was 4.875, mean pain score at discharge was 2.758, mean of the mean pain over duration of stay was 1.914, and mean maximum pain score over duration of stay was 5.373. Approximately half (49.5 percent) of patients received non-CII analgesics, 45.55 percent of patients received short-acting CII analgesics, and 27.72 percent of patients received long-acting CII analgesics. Mean morphine equivalents (MME) per day ranged from 0 to 750 MME per day, with a mean of 78.42 MME per day. A new analgesic was prescribed to 19.8 percent of patients at discharge for a mean duration of 6.5 days. Forty-five patients (44.55 percent) were on an analgesic agent prior to arrival, and 32 (71.11 percent) of those patients continued their prior analgesic agent upon discharge. Of the remaining 13 patients (28.89 percent), 10 patients had agents discontinued upon discharge, one patient changed agents entirely, one patient had agent dosage increased, and one patient had agent dosage decreased.

Conclusion: There appears to be a lack of standardization in approach to characterizing and managing pain in patients with history of OUD within our institution. There also appears to be a lack of patient information collected and available to physicians about OUD patient's nature of pain and previous management. Our institution may benefit from a protocol-based approach to pain management in patients with OUD. This protocol would potentially help physicians collect relevant patient information, guide initial regimen selection, and adjust regimens to individualized patient requirements. Further research is required to implement improvements in pain management practices in patients with OUD.

Submission Type: Evaluative Study

Session-Board Number: 2-200

Poster Title: Impact of antibiotic timing on length of stay of septic patients in a community-based hospital

Primary Author: Nina Chacko, Ernest Mario School of Pharmacy - Rutgers University, New Jersey; **Email:** nina.chacko@rutgers.edu

Additional Author (s):
Natalie Gofman
Daniel Abazia

Purpose: Treatment of sepsis involves prompt administration of fluids and antibiotics to initially manage symptoms. The 2012 Surviving Sepsis Guidelines recommend that empiric antibiotics should be given within one hour of recognition of septic shock and severe sepsis. Every hour delay of antibiotic administration is associated with increased mortality. The purpose of this study is to assess the effect of antibiotic administration on length of stay and other outcomes in septic patients. This study will also evaluate adherence to sepsis guidelines at Capital Health Regional Medical Center.

Methods: The health-system's electronic medical record was utilized to identify patients over the age of 18 years with a diagnosis of sepsis from March 1, 2016 through May 31, 2016. Patients were excluded if they developed sepsis as an inpatient or if timing of antibiotic administration was unable to be determined. Data collected included: patient demographics, labs (including white blood cell count, percent bands, and lactate level) discharge diagnosis, initial vital signs at admission, date and time of admission and discharge, days of intensive-care unit (ICU) stay, days of hospital stay, time of antibiotic ordering, time of antibiotic administration, types of cultures taken, and results of those cultures. The primary outcome of the study was to compare time to first antibiotic administration with length of hospital stay. Secondary outcomes included length of ICU stay, mortality, and adherence to the health-system's sepsis protocol.

Results: Sixty-nine patients were included. Forty-eight patients (69.5 percent) were diagnosed with sepsis, 7 patients (10.1 percent) with septic shock, 4 patients (5.8 percent) with severe sepsis, and the remaining patients had a combination of diagnoses. Antibiotics were given

empirically according to the health-system's protocol and suspected site of infection. Thirty patients (43.5 percent) received empiric antibiotic coverage with vancomycin and cefepime. The average length of hospital stay for all of the patients was 16 days plus or minus 15 days. Fifty-seven patients (82.6 percent) received an antibiotic within one hour. Patients that received an antibiotic within one hour had an average length of stay of 14.5 days plus or minus 14.9 days, whereas patients that did not receive an antibiotic within one hour had an average length of stay of 20 days plus or minus 18.4 days. The average length of ICU stay was 3.8 days plus or minus 4.5 days in the within one hour group, compared to 7.8 days plus or minus 19.5 days in the over one hour group. Eight patients (11 percent) expired during their hospital stay. Seven patients were in the within one hour group, and one patient was in the over one hour group.

Conclusion: It is critical to get septic patients urgent care as quickly as possible. Overall, there was adherence to guidelines of antibiotic administration within one hour of sepsis identification, resulting in decreased length of hospital stay. For patients who received antibiotics after one hour, several barriers were identified, such as a lack of IV line access. The health-system will continuously strive to improve barriers to administration in order to optimize patient outcomes.

Poster Title: Companion diagnostics: Current trends from a clinical development and regulatory perspective

Primary Author: Diana Destin, Ernest Mario School of Pharmacy (Rutgers University), New Jersey; **Email:** df.destin@rutgers.edu

Additional Author (s):
Shivani Shah
Kristina Vishnevetskaya

Purpose: The advent of personalized medicine has ushered a shift in both the development and approval of drug therapies. In recent years, the rise of immunotherapies and targeted therapies has also led to a crucial need to better predict patients' clinical response from these medications. The objective of this research is to evaluate current companion diagnostics on the US and European markets and compare the regulatory framework between the US and Europe. Furthermore, another goal is to illustrate the co-development process of companion diagnostics with their corresponding therapeutic products.

Methods: We performed a literature review of existing companion diagnostics, their therapeutic areas, and the regulatory processes required for the approval of companion diagnostics in both the US and Europe. Search engines included Medline, National Center for Biotechnology Information, and PubMed. We also utilized the Food & Drug Administration (FDA) and the European Medicines Agency (EMA) guidelines and guidances for regulatory information. Additionally, we examined trends in the development of companion diagnostics over the past several years, as well as the therapeutic areas represented.

Results: Currently, there are 37 FDA-approved drug-companion diagnostics combinations. The majority of companion diagnostics are geared towards oncology, but other therapeutic areas represented include HIV, cystic fibrosis, and severe growth failure. The development process of companion diagnostics generally involves preclinical trials that focus on biomarker selection. As for subsequent clinical trials, they involve prototype construction, analytical validation, and clinical validation. The FDA recommends that companion diagnostics be developed in parallel with their corresponding therapeutic product and validated in the Phase 3 clinical trial. In

Europe, there is often no cross-talk between companies, and most companion diagnostics are regulated by self declaration under the lowest risk category, "general IVD", which include all devices except Annex II and self-testing devices. Companion diagnostic tests are expected to fall into the new risk-based classifications (Class C or D) of IVD medical devices by the EMA, whereas the FDA classifies medical devices as exempt, 510(k), or PMA. Overall, both agencies understand that co-development strategies and regulatory issues for drugs present challenges within companion diagnostic projects, so it is important to establish a dialogue with regulatory authorities as early as possible in the development process.

Conclusion: Companion diagnostics offer value by individualizing therapy to improve clinical outcomes. Personalized medicine is the future of many therapies, and the increasing trend in the sales of companion diagnostics over the past several years reflects this phenomenon. In 2010, companion diagnostics generated $1.3 billion. This is predicted to increase to $11.4 billion by 2021. Health authorities are also adapting their regulatory frameworks in order to accommodate the progression of companion diagnostics. Further research may be conducted to distinguish the regulatory process for products with a companion diagnostic from that of agents without one.

Poster Title: Assessment of pharmacist interventions in hospitalized patients' medication therapy to prevent development of delirium

Primary Author: Stephanie Chung, Ernest Mario School of Pharmacy at Rutgers University, New Jersey; **Email:** st.chung13@gmail.com

Additional Author (s):
Stacy Hardeo

Purpose: The risk of developing delirium is faced by many hospitalized patients, especially those with advanced age, organ dysfunction, and use of medications that can cause delirium. Delirium can present as hallucinations or altered consciousness, and may become permanent or have fatal consequences. The Hospital Life Elder Program (HELP) at Morristown Medical Center helps prevent delirium through various measures, including therapeutic activity programs and early mobilization. Currently, there are minimal interventions related to high risk medications. The purpose of this project is to investigate the potential for pharmacist involvement in the HELP program and to standardize pharmacists' approach to these patients.

Methods: The Beers criteria, hospital formulary, and physician prescribing practices were used to develop a list with rationale and recommendations of medications to be avoided or minimized in patients at risk for delirium. Pharmacy students reviewed the medication profiles of all patients identified by HELP as a delirium risk from May 1, 2016 through May 31, 2016. They identified at-risk patients' age, sex, renal function, and high-risk medications prescribed. Patient medication profiles were further evaluated to identify potential and actual interventions related to medications that pose a delirium risk.

Results: 226 patients were identified to be at risk for delirium by HELP, with 305 potential medication interventions identified among them. 247 medication issues (81%) were identified in patients at least 75 years of age; 155 (51%) were identified in female patients, and 124 (41%) had a creatinine clearance of at least 50mL/min while 69 (23%) incidences occurred in patients with a creatinine clearance below 30mL/min. 174 patients (77%) had been prescribed at least 1 high-risk medication, with 30 (18%) of these patients receiving greater than 1 high-risk medication. High-risk medications most commonly prescribed were benzodiazepines, followed

by diphenhydramine, then sedative-hypnotics. In total, interventions were made on 96 (31%) of the possible medication issues, and of these, the majority consisted of monitoring without recommending changes to the patients' medications. 37 patients developed delirium in the hospital during this time, out of which 13 were enrolled in the HELP program. All 37 patients were prescribed at least 1 high-risk medication.

Conclusion: Many hospitalized patients are at risk of developing delirium, and pharmacists have the opportunity to help prevent delirium caused by medications. Results show that while pharmacists may be aware of the risks of certain medications in developing delirium, little is being done to reduce the medications' exposure to at-risk patients. Development and education of a tool to assist pharmacists in easily identifying high-risk medications, the rationale behind the risk and clear, specific interventions may assist pharmacists in taking a bigger role in the reduction of delirium secondary to medication interventions.

Poster Title: Characterization of hypoglycemia management in accordance with a protocol in hospitalized patients with medication-induced hypoglycemia: a retrospective analysis

Primary Author: James Young, Ernest Mario School of Pharmacy

Rutgers, The State University of New Jersey, New Jersey; **Email:** jy418@rutgers.edu

Additional Author (s):
Steven Nerenberg

Purpose: In hospitalized patients, hypoglycemia and lack of glycemic control are associated with increased morbidity and mortality. The statuses of hospitalized patients change on a daily basis making it more difficult to maintain glycemic control which allows episodes of medication-induced hypoglycemia to occur. Thus, the hospital has instituted a hypoglycemia protocol to ensure episodes of hypoglycemia are corrected appropriately and timely. The purpose of this study is to evaluate the utilization of the protocol developed for managing episodes of hypoglycemia experienced by patients admitted to the hospital.

Methods: This study was a retrospective chart review approved by the hospital's institutional review board. A list was generated from the data-mining program, Theradoc, to identify patients greater than or equal to 21 years old with a blood glucose level less than 80 mg/dL in the intensive care unit or less than 70 mg/dL for the non-intensive care unit, from July 18, 2016 to August 18, 2016. Patients were included if they had an active order for a hypoglycemic-causing medication such as insulin, sulfonylureas, or meglitinides. Patients were excluded if they had an active order for immune globulin intravenous, total parenteral nutrition or experienced an episode of diabetic ketoacidosis, calcium channel blocker overdose, or beta-blocker overdose. Demographic data, such as age, gender, weight, and length of stay was collected. In addition, the choice of intervention and blood glucose levels up to 24 hours post-hypoglycemic event were recorded. The primary endpoint was the percent of patients in which a documented intervention to correct hypoglycemia had occurred. Secondary endpoints were incidence of hypoglycemia with an active hypoglycemic medication, time to reach corrected blood glucose and if the patient had multiple hypoglycemic episodes within 24 hours.

Results: Of the 85 patients with an episode of hypoglycemia, 60 patients met the inclusion criteria. Of these patients, 27 (45 percent) were critical care patients, 56 (93.3 percent) had diabetes, and 25 (41.7 percent) were on concurrent corticosteroids. Initial episodes of hypoglycemia had an average blood glucose level of 60.95 mg/dL and included 58 patients with a concomitant order for insulin, 6 for sulfonylureas, and 2 for meglitinides. For the primary outcome, 17 (28 percent) patients had a documented intervention. The median time from hypoglycemic episode to intervention was 1.24 hours. Of the 60 patients, it took, on average, 3.57 hours from the initial episode of hypoglycemia to reach normoglycemia. In addition, 20 patients (33 percent) had multiple episodes of hypoglycemia within 24 hours.

Conclusion: The results of this study highlight poor compliance with our institution's hypoglycemia protocol. This is evident by infrequent and inconsistent documentation of interventions to reverse hypoglycemia. In addition, this study confirms that most episodes of hypoglycemia occur in patients who are receiving anti-diabetic medications. Of these episodes, older, diabetic patients managed on insulin were at increased risk. Additional education should be considered to ensure each patient receives timely hypoglycemic reversal that is documented in the electronic medical record.

Poster Title: Termination of eculizumab therapy in a pediatric patient with atypical hemolytic uremic syndrome: a case report

Primary Author: Wen-Ling Kyon, Ernest Mario School of Pharmacy, Rutgers the State University of New Jersey, New Jersey; **Email:** wk111@scarletmail.rutgers.edu

Additional Author (s):
Christine Li
Katelin Kimler

Purpose: Atypical hemolytic-uremic syndrome (aHUS) is a disease that involves dysregulation of the alternative complement pathway, which leads to complement overactivation. It is associated with thrombotic microangiopathy (TMA), characterized by a triad of microangiopathic hemolytic anemia, thrombocytopenia, and acute kidney failure. Previously, the only treatment was plasma exchange, which led to poor outcomes with almost 50% patient mortality or end-stage renal disease despite treatment. Eculizumab (Soliris®), a monoclonal antibody that targets C5 and prevents complement activation, was approved for the treatment for aHUS in 2011. However, time to response is unclear and it is unknown when to discontinue therapy when a patient seems refractory. This case report presents a 17 year old male patient with a 3 month history of right eye vision loss. Medical evaluations prior to admission revealed anemia and thrombocytopenia. Prior to admission, a bone marrow biopsy was negative for multiple myeloma but revealed abnormal lymphocytes and a PET scan revealed only abnormal adenoid tissue, which was subsequently biopsied and negative. He was admitted for fevers of 102 oF, vomiting, headache, petechial rash and nosebleeds for 2 days. On admission, his white blood cell count was 18.5, hemoglobin 11.9, platelets 63, serum creatinine (SCr) 3.0, C3 complement 23, and C4 complement 16.9. Given his renal insufficiency, thrombocytopenia, anemia, and low C3, this patient was diagnosed with aHUS and given eculizumab 900 mg IV on Day 2 of his admission. ADAMTS13 levels were checked to rule out possible deficiency, which was excluded. His SCr continued to increase, and he was put on dialysis on day 4. He continued weekly eculizumab therapy, as indicated, for 3 additional weeks, and then transitioned to every two week maintenance therapy thereafter. On day 20, he was intubated for acute respiratory failure and hypotension. Echocardiogram showed acute systolic dysfunction with ejection fraction ~40% and pulmonary hypertension. As aHUS and renal function did not resolve with

eculizumab use, the patient began plasmapheresis starting on day 20, at first on consecutive days and transitioning to three times weekly. Due to this procedure, supplemental eculizumab was given up to four times per week, as per the package insert. Plasmapheresis was effective to maintain platelet counts as this patient's admission continued, and continues to the point of this report. Eculizumab was continued on a biweekly schedule with frequent supplemental doses for plasmapheresis up to day 70, when the therapy was discontinued due to lack of clinical improvement. Subsequently, additional therapies have been added, although eculizumab remains on the list of failed therapies for this patient. Signs of refractory use of eculizumab include signs and symptoms of TMA complications, elevated serum creatinine and lactate dehydrogenase, and thrombocytopenia. These should be assessed during therapy in order to monitor drug efficacy. Based on this patient's clinical presentation throughout therapy, we recommend continued vigilant monitoring for efficacy throughout a patient's course of therapy. In addition, review of literature has described few other case reports in which time to response was demonstrated to be within two doses to one month. Due to costs and lack of added benefits, we recommend eculizumab be discontinued after one month of induction therapy without evaluable clinical improvement. This case report demonstrates a continued lack of efficacy of eculizumab therapy after an extended duration of treatment and serves to add to literature supporting a shortened course of therapy in such refractory cases.

Poster Title: Evaluation of intravenous alteplase in elderly patients with acute ischemic stroke: a retrospective safety analysis

Primary Author: Judah Brown, Ernest Mario School of Pharmacy, Rutgers University, New Jersey; **Email:** judah.brown@rutgers.edu

Additional Author (s):
Luigi Brunetti
Christopher Adams

Purpose: Intravenous alteplase, or recombinant tissue plasminogen activator (rtPA), is frequently used in the emergency setting to provide an increased chance of improved functional outcomes for patients diagnosed with acute ischemic stroke. Although alteplase has been shown to improve neurologic functioning, its outcome measures are generally restricted to younger patients (less than 80 years old) with a better chance of survival and a better ability to recover. The purpose of this study was to determine if there exists an increase risk of mortality in ischemic stroke patients aged 80 years or older with hemorrhagic conversion post alteplase administration.

Methods: This retrospective cohort study was conducted by chart review utilizing the electronic medical record and hospital discharge database from a 365-bed academic community medical center certified as Joint Commission comprehensive stroke center and was approved by the institutional review board. Patients aged 18 years and older were enrolled in the study if the patient had a primary diagnosis of ischemic stroke and received intravenous alteplase, 0.09 mg per kg bolus in addition to 0.81 mg per kg infusion of rtPA between the dates of January 1, 2012 and January 1, 2016. Patients were excluded from the study if the patient did not receive a CT scan or MRI immediately prior to rtPA administration and a minimum of 24 hours post rtPA administration. Patients were also excluded if they were transferred to a different medical institution prior to 24 hours post rtPA administration. The primary outcome measure was in-hospital mortality within 7 days of admission to the emergency department for the treatment of acute ischemic stroke. Secondary outcome measures included the composite of hemorrhagic conversion or major bleeding as defined by the International Society on

Thrombosis and Haemostasis within 7 days of admission to the emergency department for the management of acute ischemic stroke.

Results: A total of 86 patients were eligible for inclusion in the study; 35 patients were aged 80 years or older and 51 patients were under the age of 80. Of the patients aged 80 years or older, 4 patients expired compared to 0 patients in the less than 80 years of age population (11.4 percent versus 0.0 percent, p equals 0.0493). When comparing the incidence of hemorrhagic conversion or major bleeding, 8 patients aged 80 years or older bled compared to 1 patient in the less than 80 years of age population (22.8 percent versus 1.9 percent, p equals 0.0055). There were no patients in either group that experienced hemorrhagic conversion that resulted in death.

Conclusion: The use of intravenous alteplase in acute ischemic stroke patients 80 years or older was associated with a statistically significant increase in the incidence of in-hospital mortality. The composite of hemorrhagic conversion and major bleeding at 7 days post administration also showed a statistically significant increase in the elder patient population. Because older age is a unique risk factor for mortality, more research is required to strengthen the determination of causality between intravenous alteplase administration and ultimate safety endpoints.

Poster Title: Examination of the effects of multidisciplinary home visits on 30-day readmission rates in chronic obstructive pulmonary disease and pneumonia patients

Primary Author: Mary Cordon, Ernest Mario School of Pharmacy, Rutgers University, New Jersey; **Email:** maryacordon@gmail.com

Additional Author (s):
Jessica Bente
Rachel Meyers
Lucio Volino
Dawn Howard

Purpose: Hospital readmissions significantly contribute to overall healthcare costs. Programs such as the Hospital Readmissions Reduction Program now penalize hospitals with excessive 30-day readmission rates for conditions including pneumonia and chronic obstructive pulmonary disease (COPD). While Transitions of Care (TOC) programs involving interventions such as home visits have been implemented, there are few studies assessing their impact on readmission rates. The focus of this study is to evaluate the effects of home visits on 30-day readmission rates of TOC Medicare patients diagnosed with COPD or pneumonia in a community teaching hospital.

Methods: This study was approved by the appropriate institutional review boards. A retrospective chart review was performed for patients 18 years and older with a primary diagnosis of COPD or pneumonia enrolled in a TOC service from January 1, 2014 to December 31, 2015. Patients with dementia, cognitive impairment, or a language barrier, and/or patients discharged with hospice care or to anywhere other than home were excluded. Patient demographic data including age, primary diagnosis, LACE (length of stay, acuity, co-morbidities, emergency department use) index score and insurance provider were collected. Baseline home visit intervention data including home visit occurrence, associated provider(s), and readmission within 30 days were also captured. Primary endpoints included 30-day readmission rates for Medicare patients with COPD who received a home visit versus no home visit and 30-day readmission rates for Medicare patients with pneumonia who received a home visit versus no home visit. Secondary endpoints included 30-day readmission rates for all patients enrolled in

the TOC program who received a home visit versus no home visit and 30-day readmission rates for patients who received a home visit from an Advanced Practice Nurse (APN) alone versus an APN with a pharmacist. Primary and secondary endpoints were evaluated using Fisher's exact test, with an alpha of 0.05 set for significance.

Results: Of the 240 total patient charts reviewed, 189 met inclusion criteria. Medicare patients with pneumonia who received a home visit had a lower readmission rate than patients who did not receive a home visit (0 percent versus 15.38 percent, one-sided P value of 1). Medicare patients with COPD who received a home visit had a higher readmission rate than those who did not receive a home visit (25 percent versus 20.83 percent, two-sided P value of 1). The overall readmission rate for all patients enrolled in the TOC program who received a home visit was lower than in similar patients who did not receive a home visit (11.11 percent versus 14.2 percent, two-sided P value of 1). Lastly, readmission rates for patients who received a home visit from an APN alone were lower than for patients who received a home visit from both an APN and a pharmacist (0 percent versus 13.63 percent, two-sided P value of 1).

Conclusion: Overall, no significant differences in readmission rates for Medicare patients with COPD or pneumonia who received a home visit versus no home visit were observed. There were also no significant differences in readmission rates for all patients in the TOC service who received a home visit versus no home visit and for patients who received a home visit from an APN alone versus an APN with a pharmacist. Although study size was a major limitation, slight trends of decreased readmission rates in some groups were observed. Larger studies evaluating the impact of multidisciplinary home visits should be considered.

Poster Title: Perioperative administration of tranexamic acid in total hip and total knee arthroplasty: A retrospective analysis

Primary Author: Anasemon Aioub, Ernest Mario School of Pharmacy, Rutgers University, New Jersey; **Email:** anasemon@gmail.com

Additional Author (s):
Christopher Adams
Luigi Brunetti

Purpose: Tranexamic acid (TXA) is the only pharmacologic agent recommended by the American Academy of Orthopaedic Surgeons for the reduction of postoperative blood loss and transfusions following total knee arthroplasties (TKA). No guidelines are currently published for total hip arthroplasties (THA). The purpose of this study was to evaluate the introduction of TXA to one hospital's protocol and to assess whether it resulted in a reduction of blood loss and consequently a decline in transfusion requirements in patients who underwent THA or TKA.

Methods: This retrospective cohort study was conducted by chart review utilizing the electronic medical record and discharge database from a 365 bed academic community medical center and was approved by the institutional review board. Our study consisted of patients at least 18 years of age who underwent THA or TKA. The control group included patients who underwent surgery between January 1, 2012 and December 31, 2012, before implementation of the hospital TXA protocol in 2013, and the study group included patients who underwent surgery between January 1, 2014 and December 31, 2014 and received two perioperative doses of intravenous TXA. The first dose was administered before tourniquet inflation and the second after tourniquet release. Doses were chosen at the discretion of the anesthesiologist, up to 1 gram. The primary outcome measure was a drop in hemoglobin of greater than 3 mg/dL within 48 hours of surgery. Secondary outcomes included postoperative decline in hematocrit within 48 hours of surgery and the incidence of blood transfusion during hospital admission. Including 162 patients in each group would provide a power of 80 percent with a two sided alpha of 0.05 to detect an absolute difference of 7.5 percent with regard to the primary outcome.

Results: Of the 221 patients who received TXA during their THA or TKA procedure, 32.1 percent experienced drops in hemoglobin greater than 3 mg/dL from baseline versus 72.4 percent of the 279 patients who did not receive TXA (P less than 0.01). There was a 9.5 percent absolute reduction in the incidence of transfusions in patients who received TXA compared to those who did not (4.1 percent and 13.6 percent, respectively; P less than 0.01). The mean decrease in hematocrit was less in patients that received TXA (8.0 percent; 95 percent CI, 7.6 percent to 8.4 percent) than in patients who did not receive TXA (10.6 percent; 95 percent CI, 10.2 percent to 11.0 percent; P less than 0.01). There was no significant difference in the incidence of deep vein thrombosis or pulmonary embolism between the two groups.

Conclusion: Use of TXA during THA and TKA was associated with significantly fewer patients experiencing decreases in hemoglobin greater than 3 mg/dL from baseline as well as fewer blood transfusions without negatively impacting safety.

Poster Title: Evaluation of pharmacist interventions in underserved minority patients with diabetes

Primary Author: David Fett, Ernest Mario School of Pharmacy, Rutgers University, New Jersey; **Email:** davidtfett@gmail.com

Additional Author (s):
Divita Singh
Enid Morales

Purpose: Diabetes affects approximately 22 million Americans, with Hispanics at a 51 percent higher death rate from diabetes than non-Hispanic whites. Achieving diabetes control through HbA1c reduction has been shown to prevent or delay long-term complications such as retinopathy, nephropathy, and neuropathy and may decrease cardiovascular mortality. There is mounting evidence that pharmacist interventions improve outcomes in diabetes patients, however, there is limited data on the effect of pharmacist interventions in minority populations with diabetes. This study evaluates the effect of the clinical pharmacist's interventions in medically underserved and financially distressed minority patients with diabetes.

Methods: This study was approved by the local Institutional Review Board and was conducted at a Federally Qualified Health Center in New Jersey. All patients 21 years or older that were referred to the clinical pharmacist for diabetes education and therapy management from July 1, 2014 to June 30, 2016 were enrolled in the study. Baseline data, including patients' demographics, medication-related problems, interventions provided, and labs, were collected concurrently. Follow-up outcome data was collected retrospectively at 3 months, 6 months, and 1 year and included HbA1c, blood pressure, LDL, and BMI values. Interventions consisted of comprehensive diabetes and self-management education, therapy recommendations and adjustments in collaboration with the referring physician, and follow-up visits between primary care appointments. Outcomes included mean decrease in HbA1c from baseline, percentage of patients achieving HbA1c goal of 7 percent, and the percentage of patients that improved HbA1c from baseline. Additional outcomes included reduction in blood pressure, LDL, and BMI. Continuous data were analyzed using a two-tailed paired t-test and categorical data were analyzed using a chi-squared analysis.

Results: A total of 262 patients were referred for diabetes management during the study period. The mean age was 51 years, 59.2 percent were females, 69.1 percent were Hispanics, 17.6 percent African Americans, and 55.3 percent were uninsured. Interventions were provided in Spanish for 62.2 percent of the patients. There were 147 patients with HbA1c measurements at 3 months, 128 at 6 months, and 80 at 12 months. The mean baseline HbA1c for all patients was 9.82 percent. The mean decreases in HbA1c from baseline in the 3, 6, and 12 month groups were 1.81 (p less than 0.0001), 1.40 (p less than 0.0001), and 1.30 (p less than 0.0001), respectively. At baseline, 13.8 percent of patients had a HbA1c of 7 percent or less compared to 38.1 percent at 3 months (p less than 0.0001), 36.7 percent at 6 months (p less than 0.0001), and 28.8 percent at 12 months (p less than 0.01). Mean LDL decrease from baseline was 36.4 mg/dL (p less than 0.001), 22.3 mg/dL (p equal to 0.022), and 2.0 mg/dL (p equal to 0.863) at 3, 6, and 12 months, respectively.

Conclusion: Pharmacist interventions in diabetes management in underserved minority patients showed an association with improved glycemic control by significantly reducing HbA1c levels and increasing the number of patients achieving the American Diabetes Association goals for HbA1c. Although the improvement was still evident at 1 year, the magnitude decreased over time, suggesting the need for continued pharmacist interventions. Other factors may have contributed to these outcomes and a randomized controlled trial would be needed to establish a causal relationship.

Poster Title: Adherence to vitamin K usage guidelines for reversal of excessive INR in a community teaching medical center.

Primary Author: Brandon Chen, Ernest Mario School of Pharmacy, Rutgers University, New Jersey; **Email:** brandon.chen@rutgers.edu

Additional Author (s):
Yekaterina Opsha
Alison Brophy

Purpose: The use of vitamin K to reverse supratherapeutic INRs in patients taking vitamin K antagonists, such as warfarin, has clinical efficacy and utility. However, vitamin K usage is not without its own drawbacks: anaphylaxis in approximately 3 of 100,000 patients, long infusion times of 30 minutes, development of thromboembolism, and possible development of resistance to later warfarin therapy. This retrospective study was designed to examine a single institution's vitamin K usage in relation to The American College of Chest Physicians' 2012 guidelines for INR reversal as well as to educate pharmacists on appropriate orders for vitamin K.

Methods: The institutional review board approved this retrospective study. One hundred patients who were 18 years or older and received vitamin K from January 1, 2016 to May 31, 2016 were included in our analysis. Chart review selection was based off of a report generated from Cerner Power Chart and pharmacy dispensing records for the time period of interest. All patients who received vitamin K while also on warfarin were included for the primary analysis of adherence to the INR reversal guidelines. Secondary analysis included all other patients that were receiving a different anticoagulant or no anticoagulation at all.

Results: A total of 48 patients received warfarin and were included for primary analysis. The rate of guideline compliance of our institution was 62.5 percent with 30 patients receiving the correct dose and route of administration of vitamin K. Twenty of these patients necessitated rapid reversal for surgery and 10 had bleeds requiring reversal of anticoagulation. Of the 18 patients who were not given vitamin K appropriately while on warfarin, 13 patients were given vitamin K despite having no bleed, 1 was given vitamin K for a retroperitoneal hematoma that

did not require medical action at the time, 3 had no bleeds with an INR greater than 8.2 (the guideline cutoff is 10 however our system is limited to a maximum value of 8.2) that received more than the recommended 3mg vitamin K by mouth, and 1 had no bleed with an INR greater than 8.2 but was given 10mg intravenously. Of the 52 patients who received vitamin K despite not receiving warfarin as an anticoagulant, 34 patients were not receiving any anticoagulation or antiplatelet therapy at all and the other 18 received direct Xa inhibitors, heparins, aspirin, and clopidogrel.

Conclusion: Our institution was moderately compliant to the guidelines for INR reversal with vitamin K. This study has shown useful, actionable information in how to educate pharmacists with regard to vitamin K administration to improve guideline adherence.

Poster Title: Evaluation of student leadership roles and development in a United States pharmacy school

Primary Author: Sowmya Banda, Ernest Mario School of Pharmacy, Rutgers University, New Jersey; **Email:** sowmya.banda24@gmail.com

Additional Author (s):
Quanhao Fu
Evelyn Hermes-DeSantis
Mary Bridgeman

Purpose: The Accreditation Council for Pharmacy Education (ACPE) has identified leadership as a key element of personal and professional development in the 2016 Standards. Student pharmacists need to develop the necessary leadership skills to provide patient care and advance the profession of pharmacy. The purpose of this study was to evaluate whether the student leadership development opportunities offered at a U.S. pharmacy school meet the elements of leadership defined by the ACPE standards and to identify barriers currently preventing students' involvement in leadership activities.

Methods: A 21 question paper and electronic survey was developed to identify current student leadership activities and the types of organizations that provided those opportunities. Students were asked to self-identify if they had been developed as any of the following significant elements of leadership identified by the 2016 ACPE Standards throughout their professional coursework: Learner, Caregiver, Manager in the Medication Use System, Promoter for Health and Wellness, Provider, Problem Solver, Educator, Advocate, Collaborator, Includer, Communicator, Self-Aware, Leader and Innovator, and Professional. Finally, students were asked to select the primary barriers that prevented their participation in leadership activities. The survey was administered to all four professional year classes and institutional review board approval was obtained prior to data collection. The data was analyzed using descriptive statistics to determine the variability in student development among class years and identify areas for improvement.

Results: A total of 224 responses were collected from the survey with 83 responses from the class of 2020, 52 from the class of 2019, 59 from the class of 2018 and 30 from the class of 2017. A majority of participants from each professional class were female, completing the 0-6 program and had a grade point average from 3.5-4.0. Among the 14 different elements of leadership presented, Communicator, Learner and Professional were the three elements identified most frequently by the class of 2017, 2018 and 2019, while the class of 2020 identified Communicator, Self-Aware and Collaborator. Manager in the Medication Use System was least commonly identified and listed by less than 40 percent of all four classes. The class of 2017, 2018 and 2019 identified subspecialty pharmacy organizations (like ASHP, APhA, DIA) as the most common type of organization that developed them as one of the listed elements, while the class of 2020 chose nonpharmacy organizations. All four professional classes responded that the top three barriers to participating in leadership development were "Not enough time due to school work" followed by "Not enough time due to work/family/other responsibilities" and "Inconvenient logistical considerations."

Conclusion: Communicator was the most frequently identified leadership element regardless of class year. Elements of leadership that will need to be further emphasized include Manager in the Medication Use System and Provider, for which a majority of participants from all four classes evaluated the effectiveness of their skills in those areas as "neutral". The most common barriers to participation in leadership development also indicate that leadership development skills and opportunities should be integrated into professional course work as many participants face barriers to attaining them through only extracurricular organizations.

Poster Title: Implementation of a linked hypoglycemia order set with pre-packaged glucose tablets for mild hypoglycemia

Primary Author: John Daniel, Ernest Mario School of Pharmacy, Rutgers, The State University of New Jersey, New Jersey; **Email:** jdaniel18129@gmail.com

Additional Author (s):
Joseph Cruz
Jim Regan
Mary O'Connor

Purpose: Diabetes guidelines recommend orally administered glucose as the treatment of choice to manage hypoglycemia (blood glucose 70 mg/dL or below) in patients who are able to swallow. In an effort to improve patient care and ensure best practices at our institution, a multidisciplinary group drafted a hypoglycemia protocol that streamlined ordering, dispensing, administration, and documentation practices by leveraging our computerized physician order entry (CPOE) system and automated dispensing cabinets (ADCs). This descriptive report outlines the implementation of a hypoglycemia order set linked to glucose point of care tests and the financial impact of stocking unit-dosed, barcoded, glucose tablets in ADCs.

Methods: After implementation of the new hypoglycemia protocol and accompanying staff education at our institution, every patient who had a glucose point of care test (POCT) ordered automatically had linked orders for oral glucose tablets, injectable 50 percent dextrose (D50W), and glucagon added to their medication profiles for as needed (PRN) use in the event of predefined hypoglycemia. The order set was based on the protocol developed by the Diabetes Program Manager using the current diabetes guidelines and other reviewed literature. Omnicell® ADCs were stocked with barcoded and unit-dosed vials of four glucose tablets, for a total dose of 16 grams of glucose per vial. If patients experienced hypoglycemic events that warranted the use of glucose tablets, the nurse could then scan the attached barcodes on the label of the vial accounting for the full sixteen-gram dose in order to facilitate documentation in the electronic medical record (EMR). Data was collected during the three-month period pre- and post-implementation of this protocol using Omnicell® Pandora Analytics software to track the number of times nurses withdrew D50W and oral glucose tablets from the ADCs. An

analysis of cost was also performed to quantify the potential costs avoided by properly managing "mild" hypoglycemic events.

Results: The hypoglycemia protocol was implemented successfully. The linked order set and stock supply of glucose tablets in the ADCs has simplified ordering, dispensing, administration, and documentation of medications used to manage hypoglycemia at our institution. In the three months prior to the implementation of this program, nurses withdrew 64 doses of D50W from the ADCs on the general medical/surgical floors of our hospital. In the three months after implementation nurses withdrew a larger number of D50W doses (91), but 38 doses of oral glucose tablets were withdrawn on those same floors, indicating that patients had been given oral glucose tablets preferentially in some cases. The acquisition cost of one D50W dose at our institution is $7.21, whereas each vial of glucose tablets had a direct acquisition cost of just $0.08. A cost avoidance of $270.94 was captured in the post-implementation period based on the implementation of the new hypoglycemia protocol.

Conclusion: The linking of the hypoglycemia order set to the glucose POCTs sought to make it easier for nurses to access treatment options during hypoglycemic events and improve documentation of medications administered. Barcoded 16 gram doses of oral glucose tablets were stocked in ADCs in attempt to reduce unnecessary intravenous medication use and improve EMR documentation. These interventions were carried out in an effort to improve best practices and evidence-based care. Further study is needed to identify if hypoglycemia treatment options were used appropriately and if any clinical outcomes have been affected by this new practice at our institution.

Poster Title: Evaluation of hazardous drug administration in non-oncology settings

Primary Author: Kathleen Montgomery, Fairleigh Dickinson University, New Jersey; **Email:** happyrx@student.fdu.edu

Additional Author (s):
Barbara Rossi

Purpose: Historically, hazardous drugs were typically classified as anti-neoplastic agents and used in traditional oncology practice settings where safe handling practices were well established. Increasing trends in the administration of hazardous drugs in non-oncology settings may present unforeseen exposure risks to various health care workers, ancillary staff, family and extended family members. To heighten an awareness of these risks, such as inhalation and dermal exposure, and identify hazardous medications administered in non-oncology settings, this evaluation was performed. Evolving trends in the delivery of non-hazardous personalized targeted therapy medications was also included in the research.

Methods: During an elective APPE rotation, an FDU School of Pharmacy Student performed extensive and comprehensive research and review of information obtained from the NIOSH list of Hazardous Medications, NCCN guidelines and several other reputable web sites. In addition, miscellaneous trade journals were reviewed to obtain data encompassing trends in the administration of hazardous drugs in non-oncology settings as well as the evolving trends in personalized targeted therapy medications. Documentation of the use of the drugs present in the NIOSH Hazardous Drug list in non-oncology settings and the various routes of administration of these drugs was performed. Throughout the research process, periodic review of findings were discussed with APPE Preceptors to ensure the capture of appropriate data which was compiled and reflected in various tables and charts for presentation and reference.

Results: Research findings revealed significant risk of exposure to hazardous drugs during medication preparation, transport, administration, disposal and other activities performed in non-oncology settings. Research indicated the use of hazardous drugs in 22 nontraditional settings constituting a potential occupational exposure risk to the staff of these settings. In

addition, potential exposure risk exists in 14 less traditional routes of administration. Research also revealed 9 major trends in personalized medicine, encompassing chronic and rare disease states, RNAi therapies, biologics, targeted monoclonal antibodies, vaccine therapies, unique medical devices and oral formulations. The impact of many of these drug formulations on occupational safety health is largely unknown.

Conclusion: The administration of hazardous drugs in non-oncology settings has revealed unforeseen exposure risks of these medications among various health care workers, ancillary staff, family and extended family members. The need to heighten an awareness of the various administration settings, medications delivered within such practice arenas and the route of administration of these drugs, is of paramount importance to healthcare workers, ancillary staff, family and other caregivers' safety. As facilities evaluate methods to achieve compliance with the recently published USP < 800> standards, these nontraditional settings and treatment protocols must be included in assessment of risk.

Submission Category: Cardiology/ Anticoagulation

Submission Type: Evaluative Study

Session-Board Number: 2-213

Poster Title: Evaluation of clopidogrel non-responders (ECNR) at a comprehensive stroke center

Primary Author: Patricia Szmuc, Fairleigh Dickinson University, School of Pharmacy, New Jersey; **Email:** pszmuc@student.fdu.edu

Additional Author (s):
Monisha Prakash
Giselle Troncoso
Natalie Gofman

Purpose: Clopidogrel non-response or resistance occurs when there is platelet aggregation despite adequate clopidogrel therapy. Approximately 40 percent of patients do not achieve adequate antiplatelet effects despite dual antiplatelet therapy. Although there has been no consensus on the prevalence of resistance to clopidogrel, the literature suggests a range from 5 to 44 percent. Our study aims to determine the prevalence of clopidogrel resistance at a comprehensive stroke center. The secondary objective is to evaluate stroke risk factors such as age, hypertension, dyslipidemia, and concomitant use of interacting medications in patients who are clopidogrel non-responders as well as loading dose response.

Methods: This study is a retrospective chart review examining prevalence of clopidogrel non-responders using VerifyNow test results from December 24, 2013 through December 29, 2014. The information collected was based on patient demographics, diagnosis/indication for hospitalization, dose of clopidogrel, loading dose (if applicable), patient labs, co-morbid conditions, and concurrent medications. The data was reviewed to determine the prevalence of clopidogrel resistance and to analyze the possible risk factors or conditions associated to clopidogrel resistance.

Results: The cumulative prevalence of initial non-response (P2Y12 Reaction Units above 194) to clopidogrel therapy in stroke patients was 64 percent. One hundred and fifty-three patients met inclusion criteria for the study and out of these patients, 68 patients received loading doses of clopidogrel. Seventeen patients (25 percent) subsequently became responders after receiving a loading dose. Stroke risk factors were seen at the following rates in non-responders: 77.5 percent having hypertension, 60.2 percent having dyslipidemia, and 47.9 percent having

coronary artery disease. Sixty one percent of non-responders were greater than 65 years, 59 percent were on aspirin, 61 percent were on HMG-CoA inhibitors, and 24 percent were on proton pump inhibitors.

Conclusion: Determining the occurrence of clopidogrel non-response is important for the monitoring of antiplatelet therapy. When non-responders receive loading doses of clopidogrel, the ADP-induced platelet inhibition is shortened to less than 6 hours and may decrease the number of non-responders. Of the 68 percent of patients who were non-responders, only 25 percent of them were able to achieve a response after initial loading dose. Further studies are needed to determine the risk factors that predispose patients to clopidogrel non-response, effects of clopidogrel non-response on patient outcomes after stroke hospitalization and any bleeding or adverse effects related to clopidogrel non-response.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Evaluative Study

Session-Board Number: 2-214

Poster Title: Evaluation of education on use of the clinical institute withdrawal assessment for alcohol scale, revised protocol

Primary Author: Michelle Ha, Rutgers University, New Jersey; **Email:** michelle.ha@rutgers.edu

Additional Author (s):
Saba Nikpour
Mary Gayle Flannelly
A. Scott Mathis
Germin Fahim

Purpose: The clinical institute withdrawal assessment for alcohol scale, revised (CIWA-Ar) is a protocol that provides guidance for the medical staff on administration of benzodiazepines to patients experiencing alcohol withdrawal syndrome (AWS). Physicians prescribe the protocol and nurses administer medications per protocol and advocate for adjustments as needed. Proper understanding and ordering of the CIWA-Ar protocol is essential to reducing patient risk of severe withdrawal, which is associated with increased morbidity, increased mortality and prolonged length of stay. This project was designed to evaluate the impact of education on physician prescribing habits for patients with AWS at a community medical center.

Methods: This was an institutional review board-approved retrospective chart review on patients admitted for AWS from April to August 2016. Education was presented to the physicians during a scheduled noon conference and to the nurses during their monthly unit meetings. This presentation was intended to both refresh the knowledge of current residents and educate the incoming residents on the CIWA-Ar protocol per hospital guidelines. Pre and post CIWA-Ar protocol education was compared to assess three target outcomes: proper use of front-loading per hospital guidelines to reduce seizure risk in patients with a history of seizures or delirium tremens, proper use of the complete CIWA-Ar protocol to prevent onset of severe alcohol withdrawal, and selection of diazepam over lorazepam as the preferred benzodiazepine.

Results: A total of 37 treatment regimens prescribed to patients on the CIWA-Ar protocol were evaluated, 14 of which were evaluated prior to education and 23 of which were evaluated

following education. Of these regimens, 85.7 percent (6/7) were properly front-loaded before education and 87.5 percent (7/8) were properly front-loaded after education, indicating a 1.8 percent absolute improvement in the use of front-loading. Additionally, 7.1 percent (1/14) were properly assigned to the CIWA-Ar protocol before education and 34.8 percent (8/23) were properly assigned to the CIWA-Ar protocol after education, indicating a 27.7 percent absolute improvement in use of the complete CIWA-Ar protocol. Lastly, 7.1 percent (1/14) were given diazepam rather than lorazepam before education and 21.7 percent (5/23) were given diazepam rather than lorazepam after education, indicating a 14.6 percent absolute improvement in selection of benzodiazepine.

Conclusion: Education on the proper use of the CIWA-Ar protocol improved adherence. These results are helpful in identifying additional gaps in protocol adherence and in creating routine formal educational programs.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Evaluative Study

Session-Board Number: 2-215

Poster Title: Experience with idarucizumab for dabigatran reversal at a tertiary academic medical center

Primary Author: Yu Tang, Rutgers University, New Jersey; **Email:** yukaitang115@gmail.com

Additional Author (s):
Michelle Kohute
Rachael Durie

Purpose: Idarucizumab is a humanized monoclonal antibody fragment (Fab) FDA approved in 2015 for the reversal of the direct thrombin inhibitor dabigatran. Currently, there is limited clinical outcome and safety data with the use of idarucizumab. Our institution restricts the use of idarucizumab to reverse dabigatran in the presence of life-threatening bleeds or urgent surgery needed to sustain life. The purpose of this review is to describe the experience with idarucizumab for reversal of dabigatran at a 600-bed, level-2 trauma, academic tertiary center.

Methods: All patients ordered with idarucizumab between December 2015 and June 2016 were reviewed for appropriate use per the institution's restrictions. Parameters collected include indications for anticoagulation, dabigatran dose, concomitant antiplatelet medications used, patient weight, age, sex, creatinine clearance, baseline INR and aPTT, types of bleed, types of surgical interventions, and idarucizumab dose given. Outcomes collected include any reported adverse events, ICU length of stay, total hospital length of stay, and survival.

Results: A total of 16 patients were ordered idarucizumab but only 12 received the medication. The mean age of the collected population was 83.5 years old. All patients were taking dabigatran for atrial fibrillation except one patient who received dabigatran for deep vein thrombosis in addition to atrial fibrillation. Nearly half of the patients had life-threatening bleeds and needed idarucizumab for reversal. Six patients were taking aspirin in addition to dabigatran and one was taking ticagrelor. Average INR and aPTT at baseline were 1.43 and 52.9, respectively. Among those 12 patients who received idarucizumab, 2 patients received only one vial of 2.5 grams instead of two vials for the total 5-gram dose as recommended by the package insert. An average length of hospital stay was 8.9 days and ICU stay was 3.3 days. No patients

were reported to have thrombogenic adverse effects. Only 1 patient expired while the other 15 patients survived.

Conclusion: Clinical outcomes data on the use of idarucizumab for dabigatran reversal remains limited. Our institution only administered a total of 12 doses over six months. No adverse events occurred during administration and all but one patient survived to discharge. Idarucizumab is reserved for life-threatening bleeds associated with dabigatran or the need of life sustaining surgery at this academic tertiary center. Idarucizumab appears to be safe when used according to the institution's protocol along with supportive care to treat life-threatening bleeds.

Session-Board Number: 2-216

Poster Title: Safety and effectiveness of diuretic use in preterm infants

Primary Author: Priya Shah, Rutgers University Ernest Mario School of Pharmacy, New Jersey;
Email: pms165@scarletmail.rutgers.edu

Additional Author (s):
Christine Robinson

Purpose: Since pulmonary edema may result in lung injury, diuretic therapy has been used in the management of chronic lung disease to improve lung function. Risks and benefits of various diuretics for infants developing or with chronic lung disease have been analyzed in several small studies. Based on limited literature and lack of evidence for important clinical outcomes and associated adverse effects, diuretic use is generally not recommended in this patient population. The purpose of this study was to evaluate the safety and effectiveness of diuretic use for chronic lung disease in preterm infants at Morristown Medical Center.

Methods: The institutional review board approved this retrospective chart review of 25 preterm infants admitted to the neonatal intensive care unit at Morristown Medical Center who were prescribed at least one dose of diuretics for confirmed or developing chronic lung disease between June 13, 2012 and August 13, 2015. Eligible patients were identified by creating a report by resource utilization by individual resource and encounter number. Patients prescribed diuretics for other indications were excluded. Data collected included information regarding diuretic agent, indication, starting, minimum, and maximum dose and duration; adverse effects (serum electrolytes, nephrocalcinosis, nephrolithiasis, bone demineralization, and ototoxicity), duration of adverse effects, and intervention(s) for resolution; frequency of laboratory monitoring; and patient demographics including gestational age, birthweight, postmenstrual age and active diagnoses at time of diuretic initiation, daily weights, percent nipple feeding, respiratory support including the need for oxygen supplementation and extubation attempts, urine output, mortality, and length of hospitalization. The data was analyzed using descriptive statistics. The primary objective was to assess potential complications of diuretic administration. Secondary objectives were assessment of short-term improvement (within one week): changes in mean airway pressure, need for artificial ventilation, need for continuous positive airway pressure, failure to tolerate extubation, and

oxygen supplementation and long-term improvement: mortality, duration of need for oxygen supplementation and respiratory support, chronic lung disease at 36 weeks postmenstrual age, and length of hospitalization.

Results: Twenty-five preterm infants with a median gestational age of 25 4/7 weeks and median birthweight of 725 grams were included in this study. Spironolactone and thiazide diuretic combination therapy was the most frequently prescribed diuretic regimen (68 percent), followed by furosemide alone (24 percent), and spironolactone, chlorothiazide, and furosemide (8 percent). The average starting dose of spironolactone, chlorothiazide, and furosemide was 1.2 mg/kg/day, 17 mg/kg/day, and 1 mg/kg/day, respectively. The median duration of diuretic use was 36 days beginning at a median postmenstrual age of 32 6/7 weeks. Electrolyte abnormalities occurred in 84 percent of patients and included hyponatremia (29 percent), followed by hypokalemia (21 percent), and hypochloremia (17 percent). Osteopenia of prematurity (7 percent) and nephrocalcinosis (5 percent) were seen as well. Management included electrolyte supplementation (10 percent), discontinuation of diuretic therapy (19 percent), decrease in diuretic dose (33 percent), and supplementation with dose decrease or discontinuation (38 percent). Upon completion of diuretic therapy, 48 percent of infants were weaned to room air, while 52 percent continued to require respiratory support throughout their hospitalization; 24 percent low grade respiratory support and 28 percent high grade respiratory support. The median length of hospitalization was 114 days and four patients died.

Conclusion: This study shows that potential complications of diuretic use in preterm infants with or developing chronic lung disease may outweigh benefits. A majority of patients developed laboratory abnormalities and required management. Short term improvement in the level of required respiratory support was seen in less than half of patients and clinically important improvement in long term outcomes was not appreciated based on more than half of patients requiring continued oxygen supplementation and respiratory support upon diuretic discontinuation or at discharge. Risks and benefits of diuretic use in this patient population should be weighed carefully prior to initiating treatment.

Poster Title: Impact of a mentorship program on students' interests in the pharmaceutical industry

Primary Author: Lan-Anh Nguyen, Rutgers University, Ernest Mario School of Pharmacy, New Jersey; **Email:** languyen93@gmail.com

Additional Author (s):
Anna Yang
Chang Woo Han
Lucio Volino

Purpose: Over several years, student interest in the pharmaceutical industry (pharma) as a potential career path has grown due to the versatility provided by PharmD training and increase in post-doctoral programs. A growing need exists for resources that student pharmacists can use to prepare for potential careers in pharma. Mentorship with industry professionals provides an impactful connection for students to receive guidance relating to industry interests. The objective of this study is to evaluate the impact of a mentorship program, hosted by the Industry Pharmacists Organization (IPhO) School Chapter, on pharmacy students' career development and professional interests relating to pharma.

Methods: A 22-question, electronic retrospective survey was distributed via Qualtrics, a web-based survey tool, to all students (N=37) enrolled in the IPhO Fellow Mentorship Program. Data was collected over a 4-week period. Survey completion notifications were sent to students at weeks 2 and 3. Question topics included student demographics, familiarity and knowledge of pharma, interest in pharma and specific functional areas, value of the program, and impact of the program on students' professional development. This study was approved by the University's Institutional Review Board.

Results: Out of the 37 program participants, 67.6% (n=25) completed the survey. At least 80% of students reported an intension to keep in touch with their mentors in the future and identified increased interest in applying for pharma-related opportunities. The majority of the students (61%) reported a change in area of pharma interest upon completing the program. The majority of participants (greater than 53%) had positive perceptions regarding the value

and impact of the mentoring program. Most participants (76%) felt that the mentorship program taught them skills not found in a classroom environment. At least 80% of respondents learned something new regarding pharma or industry fellowships, expressed more interest in pharma-related opportunities, and would recommend a pharma-related mentoring program to other students.

Conclusion: Overall, the mentorship program proved valuable in providing education, fostering professional development, and generating further interest in post-PharmD careers in pharma. Future pharmacy programs and organizations should consider facilitating a program to expose students to pharma through a mentorship program. Future studies may focus on the effects of long-term mentorship as well as the number of post-program students who achieve their desired careers in pharma.

Poster Title: Evaluation of compliance to institutional antimicrobial stewardship guidelines for acute bacterial skin and skin structure infections

Primary Author: Yen-Ting Shoung, Rutgers University, Ernest Mario School of Pharmacy, New Jersey; **Email:** ytshoung@gmail.com

Additional Author (s):
Kaiwen Wang
Monica Shah
A. Scott Mathis

Purpose: Acute bacterial skin and skin structure infections (ABSSSI) are associated with increased hospital admissions. Frequent use of unnecessary broad-spectrum antibiotics and prolonged therapy duration is common. This may lead to antibiotic-related adverse events, such as Clostridium difficile infection, and increased length of stay (LOS). An antibiotic stewardship program (ASP) may help improve antibiotic use and outcomes for patients with ABSSSI. Compliance with ASP guidelines has shown to decrease therapy duration and LOS, which can potentially result in decreased antibiotic resistance and adverse events. The objective of this study was to evaluate compliance to institutional antibiotic stewardship guidelines for ABSSSI.

Methods: This study was approved by the Institutional Research Review Board. Adult patients, admitted with a diagnosis of ABSSSI, from April to August 2016, were randomly selected for evaluation. A retrospective review of electronic medical records was performed and data collection included patient demographics, emergency department (ED) and inpatient antibiotic utilization, blood and wound culture results, duration of antibiotic therapy, discharge antibiotics, and patient outcomes. Compliance to institutional antibiotic stewardship guidelines for ABSSSI was evaluated.

Results: A total of 30 patients were evaluated. 18 (60 percent) were females, mean age 58 years (range 24-94). The most common co-morbidities were diabetes, seen in 5 (16.7 percent) and malignancy, in 2 (6.7 percent) patients. 16 (53.3 percent) patients were obese. 11 (36.7

percent) had allergies to antibiotics, which commonly included beta-lactams and fluoroquinolones.

26 (86.7 percent) patients received antibiotics for ABSSSI in the ED. Majority of the antibiotic regimens included vancomycin, ampicillin/sulbactam, levofloxacin, and piperacillin/tazobactam. Blood cultures were collected in 25 (83.3 percent) patients and wound cultures in 12(40 percent). 11(91.7 percent) of the 12 wound cultures were positive. Only 1 (4 percent) blood culture was positive. The most common pathogens isolated included methicillin-resistant Staphylococcus aureus (MRSA), Staphylococcus epidermidis, and Pseudomonas aeruginosa. Among inpatients, 5 (16.7 percent) received ceftaroline and 25 (83.3 percent) received other antimicrobials, which most commonly included vancomycin, first-generation cephalosporins and extended-spectrum beta-lactams.

Of the 30 total patients, all received appropriate antibiotics in the ED, and 29 (96.7%) inpatients received appropriate antibiotics.

All of the patients were discharged, 5 completed antibiotic therapy during hospitalization and 25 received oral antibiotics upon discharge. The average inpatient duration of antibiotic therapy and hospital LOS was 4.33 days.

Conclusion: Overall, the use of antibiotics for ABSSSI in the ED and inpatients was appropriate and consistent with institutional guidelines. Continuous education and monitoring of institutional antimicrobial stewardship guidelines helped improve adherence.

Poster Title: Assessment of student leadership development in United States pharmacy schools

Primary Author: Anna Yang, Rutgers University, Ernest Mario School of Pharmacy, New Jersey;
Email: annayang4@gmail.com

Additional Author (s):
Sowmya Banda
Mary Bridgeman
Evelyn Hermes-DeSantis

Purpose: The Center for the Advancement of Pharmacy Education (CAPE) emphasizes that pharmacist responsibilities have expanded beyond traditional roles to include interprofessional collaboration, patient advocacy, diverse patient population care, education among various areas, and workplace management. Thus, the 2013 CAPE educational outcomes included leadership development as a desired result of pharmacy curricula. The purpose of this study is to identify current leadership development opportunities offered as curricular, co-curricular, or extracurricular activities in United States pharmacy schools and identify what future leadership initiatives are being planned to achieve updated national education standards set forth by the Accreditation Council for Pharmacy Education (ACPE).

Methods: An anonymous survey of student chapter advisors of Phi Lambda Sigma (PLS) Pharmacy Leadership Society was conducted. A 32-item electronic survey was created in Qualtrics regarding current leadership development opportunities, extracurricular activities, effectiveness of curriculum on leadership development, and future initiatives for leadership development. The survey was open for one week. Institutional Review Board approval was obtained prior to survey distribution and all participants provided informed consent prior to participation.

Results: Out of 121 participants surveyed, 54 participants completed the survey, yielding a 44 percent response rate which included schools from all 8 regions. Of the participants who completed the survey, 78 percent indicated that their school's curriculum included courses related to leadership development. Faculty were involved in teaching 98 percent of leadership development courses. Leadership experience was considered for admission in more than 70

percent of the pharmacy schools completing this survey. Over 90 percent of participants reported their schools offered extracurricular activities, including professional Greek organizations, student government specific to pharmacy, pharmacy academic recognition organizations, and professional pharmacy organizations. A majority of participants agreed that their pharmacy school curricula developed students to be self-aware, to be leaders with the ability to create and achieve shared goals, and to be professionals. However, 45 percent of participants evaluated the development of students as innovators and entrepreneurs to be neutral in effectiveness. Of the 47 percent of participants who stated that future initiatives surrounding student leadership development are being planned in their respective schools, more than half of the participants specified curricular, extracurricular, and co-curricular activities in development.

Conclusion: Surveyed PLS student chapter advisors reported that various leadership development opportunities are currently being offered or planned in pharmacy schools throughout the United States to achieve CAPE and ACPE outcomes. Many pharmacy schools are developing additional curricular, extracurricular, and co-curricular activities to supplement the leadership growth in student pharmacists. Overall, the emphasis on student leadership development in numerous pharmacy organizations and courses demonstrates the increasing relevance of leadership across curricula of United States pharmacy schools.

Poster Title: Evaluation and assessment of pharmacy students' knowledge of cultural competency, patient health literacy, and social determinants of health

Primary Author: See Gin Lee, Rutgers University, Ernest Mario School of Pharmacy, New Jersey; **Email:** sglee1992@gmail.com

Additional Author (s):
Muhammad Sheikh
Mamta Karani
Marc Sturgill

Purpose: Throughout the didactic and experiential learning of a pharmacy student, there is limited exposure to the underserved population. Factors such as low health literacy and patient activation levels have been found to be significantly associated with emergency room and hospital reutilization. It is unknown whether students are prepared to work with patients who have limited resources and socioeconomic challenges along with enough cultural sensitivity to adapt to patients' needs. The purpose of this project is to investigate the current knowledge and ability of pharmacy students at a pharmacy school in the northeast to effectively communicate with an underserved population.

Methods: The institutional review board (IRB) approved this prospective, cross-sectional study survey. Descriptive statistics was used to analyze the results. All students who completed an informed consent form and were enrolled in the 1st, 2nd, 3rd, or 4th professional years (P1, P2, P3, or P4) at the pharmacy school during the 2016-2017 academic year were eligible to participate. The survey was developed and adapted from two previously existing and validated surveys, the Underserved Knowledge Assessment and the Clinical Cultural Competency Questionnaire. Permission for use was obtained from both authors of each survey. The survey was hosted through the Qualtrics website. Students were recruited through an IRB-approved recruitment email that was distributed to eligible participants' emails during a one month time frame. The primary outcome was to assess the need for implementation of cultural competency, patient health literacy and social determinants of health education into the pharmacy school curriculum by evaluating pharmacy students' knowledge and skillset of these concepts.

Results: Over 800 students were invited to participate in the survey. 186 students enrolled with 37 being excluded due to incompletion or failing to meet inclusion criteria. 149 students completed the survey (28% P1s, 16% P2s, 19% P3s, 40% P4s). The baseline characteristics of the majority of participants were Asian, female, age between 20-25 years old, coming from a suburban, upper middle class background with their parents achieving some professional or graduate school education. Including rotations, P4s significantly received more exposure hours than P1s (p=.001729). However, through required or elective courses, majority of students received less than 10 hours of cultural competency education. Around 95% of students believed that sociocultural issues affect pharmacists' relationships with patients and healthcare professionals and that it was at least somewhat important for healthcare professionals to receive training in cultural diversity. 89% of students either strongly agreed or agreed that they would like to be involved in serving the medically needy and 95% felt that it was important for pharmacists to receive education about issues related to medically underserved populations. One third of students felt that they did not have any skills to deal with cross cultural conflicts relating to diagnosis, treatment, adherence, or ethical concerns.

Conclusion: The results of the study support the importance and emphasize the need for formalized teaching of cultural competency, patient health literacy, and social determinants of health in the pharmacy curriculum. This supports current recommendations made by the American College of Clinical Pharmacy and the accreditation standards by the Accreditation Council of Pharmacy Education for pharmacists and pharmacy students to receive this type of education.

Poster Title: Evaluation of metronidazole and oral vancomycin use for Clostridium difficile infection

Primary Author: Maria Fidelis Romero, Rutgers University, Ernest Mario School of Pharmacy, New Jersey; **Email:** mariaelise.romero@gmail.com

Additional Author (s):
Thom Nguyen
Ashmi Philips
Rani Madduri
Mona Patel

Purpose: In suspected C. difficile infection, empiric antibiotic coverage with metronidazole and/or oral vancomycin may be initiated based on risk factors, with the Infectious Diseases Society of America and American College of Gastroenterology guidelines recommending possible antibiotic initiation prior to diagnostic testing in high risk patients. Continuation of antibiotics without confirmed diagnosis potentiates resistance and adverse effects. This study will be held at a community teaching hospital, where PCR stool assay is used for diagnosis. The purpose of this study is to determine the percentage of patients who continued to receive antibiotics for C. difficile infection after negative PCR stool results.

Methods: This is an institutional review board approved retrospective medication use evaluation study. A list of patients were generated from the electronic medical record system who received metronidazole and/or oral vancomycin therapy from April to June 2016. A retrospective review was performed on patient charts to determine use of antibiotics for empiric C. difficile coverage prior to PCR stool assay results. Patients were included in the study if they were at least 18 years of age and started on empiric antibiotic therapy for suspected C. difficile infection prior to PCR stool assay results. They were excluded if they had an additional indication for initiating metronidazole and oral vancomycin. A data collection sheet was used to record the results of PCR stool assays and to determine whether antibiotic therapy was continued or discontinued in patients with a negative result. The following data was collected: age, gender, C. difficile risk factors, metronidazole and/or oral vancomycin dose and duration of therapy, time of initiation of PCR stool assay, results and time when reported, and reasons why

antibiotics were continued. The primary endpoint is the percentage of patients who continued to receive antibiotics after negative PCR stool assay results. Secondary outcomes include cost analysis of additional doses of antibiotics given, and the incidence of patients started on empiric antibiotic therapy where a confirmatory PCR stool assay test was not performed.

Results: There were a total of 32 patients included of which 22 patients were started on therapy prior to PCR results, and 11 of those patients tested negative for C. difficile infection. Of the 11 patients, 7 (63.6 percent) patients were continued on therapy for the major concern of non C. difficile infectious diarrhea. For the secondary outcome, there were 7 out of 32 patients (21.8 percent) who did not receive confirmatory PCR stool assay test. Additionally, 3 out of 32 patients were started on therapy after a negative PCR report. In terms of the cost analysis, there were 8 patients who received a range of 1 to 10 additional doses of antibiotics. The price of metronidazole ranged from 1 to 5 dollars. However the costs in additional doses of oral vancomycin ranged from 35 to 175 dollars per person. It should be noted for 2 patients that incurred a cost of 175 dollars each, one did not receive a PCR test and the other tested negative for C. difficile infection. Neither patient appeared on a C. difficile infection report during their hospital stay. Only one of those patients had an active C. difficile infection in the previous 8 weeks.

Conclusion: While patients may have been continued on therapy regardless of a negative result, the indication was appropriate for a majority of those patients. However, there were a number of patients who did not receive a confirmatory PCR test to determine appropriate therapy, which subsequently led to additional doses that were given. This study highlights the importance of the initiation of PCR stool assay tests when C. difficile infection is suspected. Antibiotic use can be further improved by checking whether PCR test results are reported prior to dosage administration.

Poster Title: Evaluation of a remote, non-emergency department pharmacy process for tissue plasminogen activator (tPA) for ischemic stroke at a community hospital

Primary Author: Parna Haghparast, Rutgers University, The State University of New Jersey, New Jersey; **Email:** parna_haghparast@hotmail.com

Additional Author (s):
Liza Andrews
Suzanne Caravella

Purpose: Despite clear benefit of an emergency department (ED) based pharmacist, not all hospitals have resources to support this model. This poses concerns for critical populations such as ischemic stroke, in which time sensitive pharmacist involvement is required. Current guidelines recommend that eligible patients receive tPA within 3 hours of symptoms (or up to 4.5 hours with additional exclusions), with hospitals administering tPA within an hour from the time patients present to the hospital. The purpose of this study is to evaluate whether this process can meet these standards when the pharmacist is based in a facility outside the ED.

Methods: Our hospital has an established process in which the ED notifies a pharmacist operating outside of the ED of a potential stroke patient and relays orders to allow for adequate lead time for evaluation, preparation and delivery of tPA. A retrospective review of all patients presenting to the emergency department and having tPA ordered between June 2015 and July 2016 was conducted. Data was collected from the medical record of patients and from the pharmacy's tPA worksheets for 42 patients. Six patients were excluded due to insufficient data or for a tPA indication other than stroke. Process data such as when the emergency room nurse called the pharmacy to inform about the presence of the patient, when the tPA order was faxed to pharmacy, when the tPA order was received by the pharmacy and the time it took for the pharmacist to prepare the tPA was collected from the internal work sheets. To evaluate whether our hospital is within the 3-hour goal from symptom onset to tPA administration, the mean time from last seen normal to the time of tPA administration was calculated. In addition, the mean time from the moment the patient presented to the emergency room and was worked up to the time the patient received TPA was calculated to see whether we reached our 1-hour goal of tPA administration.

Results: For the 36 patients receiving tPA for ischemic stroke in our community-based emergency department over a 13 month period, the mean time from which the patients were last seen normal to the actual time the patient received tPA was 2.20 hours. The mean time from the moment the patient presented to the ED to tPA administration was 54.26 minutes and the mean time it took the pharmacists to prepare tPA was 7.2 minutes.

Conclusion: This quality assessment supports that collaboration between emergency department nurses and physicians with a pharmacist outside of the emergency department in our community hospital allows for tPA to be administered within the required timeframe for patients presenting with ischemic stroke.

Poster Title: Assessing cost-effectiveness trials that evaluate integration of a clinical pharmacist into primary care settings for disease-state management of psychiatric conditions

Primary Author: Daniel Dipsia, Rutgers, The State University of New Jersey, New Jersey; **Email:** dipsiadaniel@gmail.com

Additional Author (s):
Caitlin McCarthy

Purpose: Uncontrolled psychiatric conditions are known causes of heath care burden and reduced quality of life. Efforts should be made to improve care delivery and consider unique strategies for comprehensive management. As medication experts, clinical pharmacists are well positioned to collaborate with primary care providers (PCPs) to optimize outpatient management of psychiatric illnesses in a cost-effective manner. However, few randomized-controlled trials (RCTs) exist to illustrate this point. This systematic review was designed to assess available literature to determine cost-effectiveness of incorporating pharmacists into a collaborative care model for the treatment of psychiatric conditions and to spread awareness of an unmet need.

Methods: A literature review was performed using evidence-based databases that included MEDLINE, Pubmed, Cochrane Library, ScienceDirect, Google Scholar and reference lists of retrieved articles. The following search terms were utilized: pharmacist, outpatient care, primary care, collaborative care, disease state management, depression, psychiatric conditions, mental health, cost-effectiveness, and cost-benefit analysis. Articles were included in the analysis if they met the following inclusion criteria: 1) patients in the trial received disease-state management from a pharmacist in a primary or collaborative care setting, 2) the primary diagnosis of interest included one or more psychiatric condition(s) and, 3) trials used a validated cost-effective measurement. Only randomized-controlled trial (RCTs) published through August 2016 were considered. Articles meeting inclusion criteria were compared and contrasted. Each study was assessed based on trial design, primary outcome measures, cost-effectiveness measures, cost calculations, results, and conclusions.

Results: Seventy-three articles were screened for inclusion, of which thirty-four assessed cost-effectiveness. Studies were excluded if the primary disease state of focus was not a psychiatric condition (n=19) or if the patients were not managed by a pharmacist in a collaborative practice or primary care setting (n=12). Three studies met full criteria for inclusion (Studies A, B, and C). Studies A and B evaluated the impact of community pharmacist-led coaching on antidepressant adherence. Study C evaluated the difference in cost-effectiveness between onsite practice-based collaborative care (PBCC) and telemedicine-based collaborative care (TBCC). PBCC included onsite PCPs and nurse depression care managers (DCMs). TBCC included onsite PCPs and an off-site psychiatric team comprised of a DCM, psychologist, psychiatrist, and clinical pharmacist. Primary cost-effectiveness measures differed among studies. Measures included quality-adjusted life years (QALYs), direct and indirect health care costs, indirect non-health care costs, and societal perspectives. Studies A and B did not find statistically significant differences between groups regarding cost or clinical outcomes. While Study C did not directly measure pharmacist interventions, differences in health care costs between the groups were not statistically significant, whereas clinical outcomes were slightly better in the TBCC group.

Conclusion: Given the complex nature of psychiatric conditions, management can be challenging. Incorporation of clinical pharmacy services into standard practice may offer a cost-effective option to improve care delivery and patient outcomes. However, too few studies exist to show the cost-benefit of pharmacist-delivered disease-state management of psychiatric conditions. Of available studies, significant limitations exist, including small sample sizes, high withdrawal rates, and short follow-up periods. Additional cost-effectiveness studies are warranted to establish the impact pharmacists may have on outcomes associated with psychiatric disorders.

Poster Title: Assessment of the use of venous thromboembolism prophylaxis in post-traumatic brain injury patients

Primary Author: Raghad Saadi, Rutgers, The State University of New Jersey, New Jersey; **Email:** rsaadi94@gmail.com

Additional Author (s):
Steven Nerenberg
Kimberly Brandt
Robert Madlinger

Purpose: Trauma patients are at higher risk for venous thromboembolism (VTE), and traumatic brain injury (TBI) in particular is considered an independent risk factor for VTE. When prophylaxis is delayed beyond 48 hours, TBI patients are three to four times more likely to develop a VTE. Despite the high risk for thromboembolism, controversy often surrounds the decision to initiate pharmacologic VTE prophylaxis because of the potential for bleeding risk complications. The purpose of this study is to evaluate thromboembolic prophylactic therapy in TBI patients for variation in practice, appropriateness of regimen, and efficacy to identify areas of potential improvement in therapy.

Methods: This study was a retrospective chart review approved by the institutional review board. The trauma registry identified patients diagnosed with moderate to severe TBI with a Glasgow Coma Scale (GCS) score of 3-12 from June 1, 2015 to May 31, 2016. Patients 21 years or older who were admitted into the surgical intensive care unit were included if they had a stable CT scan, defined by a radiologist's impression indicating a stable or improving bleed. Patients were excluded if they had a contraindication to pharmacologic VTE prophylaxis, or if they died or were discharged within the first 24 hours. Information collected included admission location, age, gender, weight, height, body mass index, creatinine clearance, admission GCS score, Injury Severity Score, any fatalities, and data associated with thromboembolic prophylactic therapy including time to stable CT scan, time to initiation of prophylaxis, the regimen administered, and incidence of side effects. The primary endpoint assessed was the time to initiation of VTE prophylaxis after a stable CT scan. Secondary efficacy endpoints assessed were the incidence of VTE, stratified into categories reflecting time to

initiation of prophylactic therapy and into categories based on the VTE prophylaxis regimen administered. Secondary safety endpoints assessed were the incidence of adverse effects, including major bleeding leading to a hemoglobin drop of 2g/dL or greater, or bleeding in a critical area, and in-hospital mortality.

Results: Of the 60 patients identified by the trauma registry, 32 patients met inclusion criteria. After a stable CT scan, 4 patients (12.5%) did not receive VTE prophylaxis, 5 patients (15.63%) received VTE prophylaxis within 0 to less than 24 hours, 5 patients (15.63%) within 24 to 48 hours, and 18 (56.25%) patients after 48 hours. The mean time to prophylaxis initiation was 65.26 hours. While there was no statistically significant difference in baseline demographics, patients with a lower GCS tended to have delayed prophylaxis. VTE was diagnosed in 4 patients, 1 of which received prophylaxis within 24 to 48 hours, and 3 of which received prophylaxis after 48 hours post-stable CT scan. All 4 patients received regimens indicated for medical patients: 2 patients were on enoxaparin 40 mg every 24 hours, and 2 patients were on heparin 5000 U every 8 hours. A major bleed occurred definitively in 1 patient in the less than 24 hours group, and a hemoglobin drop of 2 or greater was seen in 5 additional patients with no associated bleed. No patients developed heparin induced thrombocytopenia. All 7 fatalities were associated with the initial injury and not due to a complication of VTE prophylaxis therapy.

Conclusion: The majority of patients in this study received prophylaxis after 48 hours. While the results are not conclusive with regards to optimal timing for initiation of prophylaxis, they do confirm the increased risk for VTE with delayed prophylaxis. Administration of prophylaxis earlier than 24 hours post-stable CT scan was associated with increased risk of major bleeding. Of note, all incidences of thromboembolism occurred in patients receiving medical dosing of prophylaxis, presenting an opportunity to improve our dosing strategy. Additional studies looking at a larger scope of patients are recommended to determine the optimal timing for initiation of VTE prophylaxis.

Poster Title: Retrospective study on time to antibiotic administration in septic patients

Primary Author: Marina Shahat, Rutgers, The State University of New Jersey

Ernest Mario School of Pharmacy, New Jersey; **Email:** marinashahat22@gmail.com

Additional Author (s):
Ashmi Philips
Rani Madduri
Thom Nguyen
Mona Patel

Purpose: The Surviving Sepsis Campaign recommends administering empiric antibiotics within one hour of diagnosis of sepsis. Currently, it is estimated that sepsis begins outside of the hospital for approximately 80 percent of patients, making early antibiotic administration vital. According to Kumar et al, each hourly delay from administering antibiotics after diagnosis results in an increase in mortality of 7.6 percent. At our institution, there is a sepsis committee that evaluates time to initiation of antibiotics. The purpose of this study is to determine if patients received antibiotics within one hour after diagnosis of sepsis.

Methods: This is an institutional review board approved retrospective medication use evaluation study. A list of patients who met the inclusion criteria was generated from the electronic medical record system. Patients who are included in this study are septic patients greater than or equal to 18 years old who received at least one dose of antibiotics from December 2015 to March 2016 and all other patients were excluded. A data collection sheet was utilized to record if patients received antibiotics within one hour of sepsis diagnosis. The data that was collected includes: patient age, gender, race, height, weight, body mass index, antibiotic allergies, condition that led to delay to treatment of sepsis, previous hospital admissions for sepsis, microbiological cultures, antibiotics administered, antibiotics available in Pyxis, time to initial infusion of the first antibiotic, and various time points in the steps taken to prepare and deliver an antibiotic. The primary endpoint of this study was the percent of patients who receive antibiotics within one hour of sepsis diagnosis. The secondary endpoint was the average time to administration of antibiotics after sepsis diagnosis. This study was utilized to evaluate if septic patients are receiving antibiotics within one hour of diagnosis. The

results of this study were used to improve the performance of the process of antibiotic preparation and administration in septic patients.

Results: There were a total of 102 patients evaluated in this study; however, 9 patients were excluded from this study due to no diagnosis of sepsis. Of these 9 patients, 7 did not receive antibiotics. The percent of patients who received antibiotics within one hour of sepsis diagnosis was 69.8 percent. There were 65 patients who received antibiotics within one hour of sepsis diagnosis and 28 patients who did not. Additionally, the percent of patients who received a combination of antibiotics within one hour of sepsis diagnosis was 56 percent. The average time to antibiotic administration in septic patients was 68 minutes. The time to antibiotic administration after sepsis diagnosis ranged from 4 minutes to 6 hours.

Conclusion: Treatment of sepsis requires a multifaceted approach in order to optimize patient outcomes. Early antibiotic administration as well as intravenous fluid resuscitation are essential to decrease mortality. Most patients at this institution received antibiotics within one hour of diagnosis of sepsis, subsequently; the patients who did not were hypotensive and received fluid resuscitation. This study demonstrates the importance of applying a multifactorial approach when treating septic patients. The clinical significance of these findings may be determined through further studies.

Poster Title: Gap analysis for an initiative to optimize inpatient proton pump inhibitor usage

Primary Author: Rachel Bigos, Rutgers, The State University of New Jersey

Ernest Mario School of Pharmacy, New Jersey; **Email:** rbigos1@gmail.com

Additional Author (s):
Timothy Reilly
Whitney Hung

Purpose: To determine what gaps exist between the optimal use of proton pump inhibitors (PPI) and the current standard of care.

Methods: A list of patients who received intravenous (IV) pantoprazole was generated over 14 days. All patients who were receiving intravenous pantoprazole were included in the analysis; patients were excluded if they had already been converted to oral (PO) pantoprazole or if pantoprazole had been discontinued. All patients were evaluated for conversion to oral therapy based on hospital protocol. The indication for pantoprazole and the outcome of the attempted oral conversion was noted. Prior-to-admission treatment and discharge with proton pump inhibitor therapy was also documented.

Results: 97 patients were evaluated. Of those patients, 47 (48.4%) were receiving PPI therapy at home, while 45 (46.4%) were newly initiated; 5 patients (5.2%) did not have medication reconciliation performed. Five indications for PPI use were identified as inappropriate in 22 of the 97 patients (abdominal pain, diverticulitis, nausea, obstruction, and corticosteroid use). Of these 22 patients, 8 qualified for IV-to-PO conversion, based on the successful administration of other oral medications. 2 of these 8 patients (25%) were successfully converted to PO pantoprazole. Seven indications for PPI use were identified as appropriate in 75 of the 97 patients (epigastric pain, gastrectomy, gastroesophageal reflux disease, gastrointestinal bleed, continuation of home medication, esophagitis, and stress ulcer prophylaxis in select patients). Of these 75 patients, 15 qualified for IV-to-PO conversion, while 10 of these 15 patients (66.7%) were successfully converted. Barriers to IV-to-PO switch included patient discharge immediately upon tolerance of other oral medications and denial by the medical team due to clinically significant nausea. Additionally, out of 45 patients who were newly initiated on PPI therapy, 13

(28.9%) did not have appropriate clinical indications for the use of acid-suppression therapy. 4 of these 13 patients (30.7%) were discharged home with a PPI.

Conclusion: Optimization of proton pump inhibitor therapy is an important intervention that allows the pharmacist to close various gaps in care. Through the conversion of IV to PO pantoprazole, the prevalence of parenteral medication administration was decreased. Provider education, an approved hospital protocol, and more consistent monitoring of indications for PPI therapy may further improve appropriateness of PPI therapy, thus leading to decreased incidence of unnecessary PPI therapy at discharge.

Poster Title: Effects of Dioxin Based Exposure in Western Kanawha County, WV

Primary Author: Frank Annie, Not In pharmacy School no other option in this section, Not In pharmacy School no other option in this section; **Email:** fha13@my.fsu.edu

Additional Author (s):

Purpose: We hypothesize when patient's cancers such as: Colon and Bladder cancer, are paid by public based insurances, the patients will have a higher survival rate than those with other forms of insurance including private and cash pay.

Methods: The primary outcome of median overall survival was assessed for each insurance category within each cancer type. After data was collected, a multivariate analysis was completed for each cancer. Kaplan-Meier Curves as well as a Cox Proportional Hazards Model were created using Stata 11.2 for each cancer. Kaplan–Meier Curves are one of the best methods to estimate the survival of subjects after their treatment has been received. When constructing the survival analysis time event within this study, it involved the enrollment of patients that have been diagnosed with Bladder and Colon Cancer. For Colon Cancer, 2 data sources were considered because of the larger data set of N = 2,267 which allowed for a wider variety of insurance to be studied. For Bladder Cancer the variety examined was less because of the smaller data set of N=596 which only included 6 insurance types. For any insurance type 5 or lower, patients were dropped because of the extremely small sample size. The Kaplan Meir Survival Curve is defined as the probability of surviving after a certain event which is usually treatment.

Results: Both Medicare and PEIA appeared to have the longest survival rate of any curve observed. Managed Care lasted almost as long as Medicare and PEIA but trailed off. The Chi Squared test was used to assess the significance of the Cox Proportional Hazards Model. A total of 2,854 patients were included in the analysis, including 596 patients with Bladder Cancer and 2,267 patients with Colon Cancer (Tables 1-2). The ages of patients at diagnosis were primarily 65 – 90. The Kaplan Meier results illustrate that for Bladder Cancer, Medicaid with (22 cases) had the longest survival rate and this was most likely due to the low sample size. Medicare (145 cases) had the second longest survival time. PEIA (West Virginia State Pension Insurance with

(311 cases) allowed a Kaplan Meier curve all the way to 0 survival because of the continued pension fund of the program and continued data set. Medicare (145 cases) had approximately 40 percent of the patients still living at the end of the patient data. Colon Cancer had a large sample size (N =2,267) with PEIA (1,275 cases) having the longest survival rate while Medicare (431 cases) and Managed care have the next longest survival rates.

Conclusion: Of all the insurance groups, Federal and State plans seemed to indicate there is supportive evidence that well supported Federal and State funds are necessary to insure a higher survival rate in either type of cancer.

Poster Title: Ethical and economic perspectives regarding coverage policies related to expanded naloxone access efforts: a systematic review of the evidence

Primary Author: Andrew Gaiser, Duquesne University, Pennsylvania; **Email:** gaisera1@duq.edu

Additional Author (s):
Khalid Kamal
Vincent Giannetti

Purpose: Drug related overdose deaths have reached epidemic levels in the US. In response to this public health crisis, there have been statewide initiatives to increase access to naloxone, a lifesaving overdose reversal agent. However, little is known regarding the ethics and economics of expanded access to naloxone and subsequent coverage policies. This systematic review explores these areas and identifies gaps in the existing literature. The review will form the basis of a content analysis of pharmacies' distribution policies, as well as assist in generating interview questions for stakeholders such as payers and clinicians involved with naloxone dispensing, coverage, and access.

Methods: The systematic literature review was conducted as per the Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) guidelines. Articles were searched in relevant healthcare databases (PubMed, CINAHL, PsycInfo) and articles that met the inclusion criteria were abstracted and summarized. Key search terms utilized in combination with naloxone to identify articles included economics, reimbursement, out-of-pocket cost, ethics, distributive justice, stigma, attitudes, beliefs, coverage policies, access, distribution, and dispensing. The student investigator examined each of the healthcare databases to identify relevant articles and completed a detailed data extraction log that included all the desired information relevant to this review. The extracted data was matched against original articles and if there was a disagreement, it was adjudicated by other investigators. Articles were selected based on predefined inclusion and exclusion criteria and the search was conducted from January 2012 to September 2016. Articles were excluded if they were in a language other than English, randomized control trials, other review articles, or articles regarding opioid substitution therapy or treatment modalities for addiction and overdose treatment other than naloxone. Articles involving administration, training, education, or pharmacology of naloxone

were excluded from this analysis as well. The article selection process involved identification of articles based on study titles and bibliographies of identified articles. Articles that met the inclusion criteria were then included in the final review.

Results: A total of 2,072 articles were screened using PRISMA guidelines and 24 relevant citations were included in the final review. 10 studies were conducted in the US and five were international studies from countries including Australia, Finland, Russia, and Scotland. Very few of the studies and articles included in this review discussed economic and ethical issues in tandem. The majority (n=19) discussed each of these content areas in isolation, or alternatively, only included a cursory exploration or acknowledgment of the other area of interest. A total of 10 studies (41.6%) evaluated economic issues, nine (37.5%) focused on ethical issues and five (20.8%) on a combination of the two issues. Several ethical concerns were identified in regards to naloxone distribution practices, including stigma associated with addiction-related health issues, pharmacists' attitudes and practices in relation to dispensing and counseling, and concern with enabling addiction. In reference to the exploration of the naloxone cost and coverage objectives of this review, identified issues included pharmacy reimbursements for naloxone dispensing, access to and costs of naloxone rescue preparations, approved product indications, and the potential for availability of OTC naloxone preparations.

Conclusion: While the majority of the studies examined showed that pharmacists are willing to participate in expanded naloxone distribution efforts to increase access to this lifesaving antidote, stigma and access, attitudes, practices and equitable distribution remain important practice and policy issues. While broad ethical, pricing, and coverage determination concerns were identified, further investigation into the specifics of these considerations in relation to naloxone dispensing and coverage is warranted. The results of this review can be used to inform future investigation aimed at further dissecting the concerns and identifying the gaps and addressing the potential barriers that may hinder naloxone access.

Poster Title: Formulation specific hormonal contraceptives and breast cancer subtyping: a retrospective study

Primary Author: Jesse Dorchak, Duquesne University Mylan School of Pharmacy, Pennsylvania; **Email:** dorchakj@duq.edu

Additional Author (s):
Joseph Guarinoni
Paula Witt-Enderby
Stella Somiari
Craig Shriver

Purpose: Given that many forms of breast cancer are hormonally dependent, hormonal contraceptives (HCs) have gained much attention as a potential risk factor in breast cancer incidence. While HCs carry warnings for increased risk of breast cancer, the literature remains split on this topic; however, it has been suggested that the progestin component and certain patient demographics may be responsible for the increased risk. This study evaluates the differences in breast cancer pathology among patients that ever used one of three HC agents.

Methods: This study received appropriate IRB approval through the Clinical Breast Care Project (CBCP) and Duquesne University. All subjects were duly consented patients attending clinics of the CBCP at Walter Reed National Military Medical Center (Bethesda, MD), the Joyce Murtha Breast Center (Windber, PA), and Anne Arundel Medical Center (Anne Arundel, MD). Data was queried from December 2000 to September 2015 from CBCP Core Questionnaires and Pathology Checklists, identifying 4299 patients who had ever used HC agents. This number was further narrowed to 656 patients based on complete contraceptive and breast pathological history. In order to evaluate the risk of specific progestins on breast cancer subtyping, three HC agents were studied: Lo Ovral, Ortho Tri-Cyclen, and Ortho Novum. Pathological subtypes were categorized as benign, ductal carcinoma in situ (DCIS), luminal A, luminal B, Her2 positive, or triple negative (TN). In order to evaluate patient demographics, seven common risk/protective factors were selected based on current literature. StatPac statistical calculator was utilized for calculating t-tests. All calculations were set at a 95% confidence interval where $p < 0.05$ was considered statistically significant.

Results: Of the initial 4299 patients who had ever used HCs, 39.5% had a benign diagnosis while 59.1% had a malignant diagnosis (p < 0.0001). After narrowing to 656 patients, the average age at diagnosis was 41.35 years; mean BMI of 26.12; began utilizing HC agents at a mean age of 20.4 years; and utilized HCs for an average of 10.92 years. Of the 656 patients, 62.7% had a benign diagnosis and 37.3% had a malignant diagnosis (p < 0.0001). When stratified by HC, patients who used Ortho Tri-Cyclen were more likely to have a diagnosis under the age of 40 (p < 0.0001) and demonstrated a trend favoring a negative family history (p=0.0848) while patients who used Ortho Novum were more likely to be Caucasian (p=0.0041) and have an increased risk of malignant pathologies (p=0.0052). Overall, the ever use of HCs was associated with more luminal A pathologies. When stratified by HC, Lo Ovral showed no statistical differences in breast cancer subtyping, Ortho Tri-Cyclen decreased luminal A (p=0.0474) and demonstrated a trend towards an increase in DCIS (p=0.0758), and Ortho Novum showed an increase in DCIS (p=0.0205) and demonstrated a trend towards an increase in Her2 (p=0.0833) and TN (p=0.0647) breast cancer pathologies.

Conclusion: For the first time, this study evaluates three HC agents, confirming all progestins do not contribute equally to the overall risk of breast cancer while proving that differences in pathological subtyping exists between progestins. Clinically, norgestimate was least likely and norethindrone was most likely to precipitate a difficult to treat malignant pathology. Given the mean age at diagnosis, the ever use of HC agents is an acceptable risk factor for beginning annual mammograms at age 40.

Poster Title: Evaluation of the impact of pharmacist-run tobacco cessation classes on abstinence rates in patients of a patient-centered medical home (PCMH) practice

Primary Author: Angela Raymond, Duquesne University Mylan School of Pharmacy, Pennsylvania; **Email:** raymonda0304@gmail.com

Additional Author (s):
Lauren Wolfe
Jamie McConaha
Gibbs Kanyongo

Purpose: Even with the resulting decline in cigarette smoking from 42 percent in 1965 to 18 percent in 2012 following the initial US Surgeon General's Advisory Committee report on smoking and health, over 42 million Americans still smoke. Guidelines explicitly advocate for the combined use of counseling and medication(s) as the most effective means to improve cessation rates. This study evaluated abstinence rates of patients that attended pharmacist-led group tobacco cessation classes in conjunction with tobacco cessation medications compared to those who utilized medications alone.

Methods: The practice site for this study was an independently owned physician group consisting of 21 offices located throughout the Pittsburgh region. Patients with a documented active smoking status in the electronic medical record (EMR) of a patient-centered medical home (PCMH) beginning July 2013 through October 2015 were invited to attend a pharmacist-led tobacco cessation class titled The Courage to Quit. Study inclusion criteria for the intervention group included the use of nicotine replacement treatment (NRT), bupropion, or varenicline and attendance in at least 3 of the 4 the classes. An EMR report was used to identify patients for the control group who utilized NRT, bupropion, or varenicline during the same time frame but did not attend the class. Tobacco abstinence rates in both the control and intervention groups were assessed telephonically at 2, 4, 12, and 24 weeks following treatment. If any patient from the control or intervention group reported continued nicotine use, they were offered an opportunity to attend future smoking cessation classes.

Results: Of the 80 patients who had previously taken The Courage to Quit classes, 30 patients met the inclusion criteria and consented to involvement in the study. The control group of 30 patients was determined based on smoking cessation treatments utilized in the intervention group and by consent to study participation. The primary endpoint, cessation at 24 weeks, was identical between intervention and control groups (26.7 percent). The most prevalent reason for relapse amongst both control and intervention groups was identified as stress.

Conclusion: There are many factors that can influence success with smoking cessation including personal desire, motivation, co-morbid conditions, support, and additional resources. While overall cessation rates did not differ between the groups, patients who attended The Courage to Quit classes may be better equipped with the knowledge and resources necessary to be successful with future quit attempts.

Poster Title: Antibiotic prophylaxis failure among patients with spontaneous bacterial peritonitis: influence of antimicrobial agent, body mass index and prognostic score

Primary Author: Alexis DeLeo, Duquesne University Mylan School of Pharmacy, Pennsylvania;
Email: deleoa@duq.edu

Additional Author (s):
Elizabeth Travers
Matthew Gatchel
Nicholas Verna
Priya Tomy

Purpose: Patients with a history of spontaneous bacterial peritonitis (SBP) or who meet criteria for primary prophylaxis are prescribed antimicrobials based upon clinical guidelines, allergies and local susceptibilities. Several prophylactic regimens are prescribed and due to conflicting data, the ideal regimen to prevent subsequent infections is unclear in patients who are obese or across various MELD-Na (Model for End-stage Liver Disease [Sodium]) scores. The goal of this study is to compare the prophylactic failure for SBP by hospital admission among cirrhotic patients with SBP, with a focus on stratification across different body mass indices and MELD-Na scores.

Methods: This study was a retrospective health system cohort analysis of patients with cirrhosis receiving antimicrobial prophylaxis for SBP who presented to a network hospital. Data was extracted from the health system electronic medical record database via International Classification of Disease 9 – Clinical Modification (ICD-9 CM) coding for cirrhosis (571.2, 5, 6) and SBP (567.23) among hospitalized patients. The following data points were collected: patient demographics, laboratory values contributing to the calculation of MELD-Na scores, presenting symptoms, paracentesis results and microbial culture(s), prophylactic antimicrobial agent(s) used including dose and frequency, home medications, empiric SBP treatment and length of hospital stay. Patients were excluded if they were not on antimicrobial prophylaxis, were not treated for SBP during this admission or if there was a secondary source of intra-abdominal infection. The primary outcome was to determine the influence of body mass index (BMI) classification upon failure of SBP prophylaxis agents. BMI indices were defined based upon the

World Health Organization classification. Descriptive statistics were utilized for patient characteristics, and Chi-square analyses were used to compare prophylaxis failures between obese and normal body weight individuals. This study was approved by Duquesne University and University of Pittsburgh Medical Center institutional review boards.

Results: A total of 700 admissions were screened; 113 admissions (92 patients) were included for analysis. Among the cohort, 66.3 percent were male, 92 percent were Caucasian, and the average age was 56.5 years. The most prevalent etiologies of cirrhosis were alcohol (54.9 percent), hepatitis C (34.5 percent) and nonalcoholic steatohepatitis (19.5 percent). All but one admission received prophylactic treatment with either sulfamethoxazole/trimethoprim (SMX/TMP; 28.6 percent) or a fluoroquinolone (71.4 percent) prior to admission. A total of 42.5 percent of antibiotic failures were among underweight/normal patients, 31 percent were overweight and 26.5 percent were obese. The BMI distributions of patients between the SMX/TMP and fluoroquinolone treatments were approximately equal: underweight/normal (43.8 vs. 41.3 percent), overweight (31.3 vs. 31.3 percent) and obese (25.0 vs. 27.5 percent). The proportion of failures for SMX/TMP and fluoroquinolones stratified by BMI were similar, showing no indication that BMI or antibiotic choice affected prophylaxis failure. Among admissions with data available to calculate a MELD-Na score, more patients failed SMX/TMP with a MELD-Na less than 30 (70.97 percent) compared to patients receiving fluoroquinolones (43.43 percent). For patients with MELD-Na scores greater than 30, failures among patients receiving fluoroquinolones were higher (56.57 percent) compared to SMX/TMP (29.03 percent).

Conclusion: Based on the results of this study, there does not appear to be an association between BMI and prophylaxis failure among patients with SBP. However, failures varied according to antibiotic and MELD-Na score, with patients at lower MELD-Na scores experiencing less failures when treated with fluoroquinolone prophylaxis, and patients with higher MELD-Na scores experiencing less failures when receiving SMX/TMP prophylaxis. Further research is needed to see if discovered trends persist among larger sample sizes, and to further investigate the influence of weekly vs. daily dosing of fluoroquinolones.

Poster Title: Evaluation of adding intravenous antibiotics to ICU automated dispensing cabinets and the effect on time to administration in patients with sepsis or septic shock

Primary Author: Alvina Tran, Duquesne University Mylan School of Pharmacy, Pennsylvania; **Email:** alvina.tran@gmail.com

Additional Author (s):
Alaina Koval
Katherine Hilton
Lauren Finoli

Purpose: The Centers for Medicare & Medicaid Services (CMS) identify time to appropriate antibiotic administration as a core measure for the treatment of sepsis and septic shock due to studies showing its direct effect on mortality. In previous studies, automated dispensing cabinets (ADCs) have been demonstrated to enhance provider access to antibiotics for the prompt treatment of infections in hospitalized patients. The purpose of this study is to determine the effect of ADCs on time to antibiotic administration for patients in the ICU diagnosed with sepsis or septic shock.

Methods: The study was designed as a retrospective cohort, pre-post analysis of patients ages 18-89 admitted to the medical intensive care unit (MICU) who were first ordered and administered either intravenous ciprofloxacin or cefepime for the treatment of sepsis or septic shock while in the MICU at a tertiary care center. Patients were excluded if they received their first dose of ciprofloxacin or cefepime in the emergency department prior to admission to the MICU. Pregnant and incarcerated patients were also excluded from this study. The primary outcome looked at time to antibiotic administration prior to intravenous ciprofloxacin and cefepime being added as stock to ADCs compared to time to antibiotic administration after stock was added to ADCs. Secondary outcomes included CMS sepsis core measure compliance pre and post implementation, rate of compliance to CMS sepsis core measure, in-hospital mortality, and ICU length of stay. This study was approved by the Allegheny General Hospital Institutional Review Board.

Results: A total of 60 patients were included in the final analysis, 31 patients in the pre-intervention group who received intravenous ciprofloxacin or cefepime prior to these antibiotics being available in the MICU ADCs and 29 patients in the post-intervention group who received intravenous ciprofloxacin or cefepime after these antibiotics were placed in the MICU ADCs. The mean time to antibiotic administration pre-intervention was 384.8 minutes and post-intervention was 181.9 minutes, a difference of 202.5 minutes (a 47.3% decrease in time).

Conclusion: Adding intravenous antibiotics to automated dispensing cabinets decreased time to antibiotic administration in sepsis and septic shock patients admitted to the medical intensive care unit at a tertiary care facility.

Poster Title: Pharmacokinetic assessment of oral voriconazole and posaconazole delayed release tablets in patients with acute myeloid leukemia

Primary Author: Matthew Gatchel, Duquesne University Mylan School of Pharmacy, Pennsylvania; **Email:** gatchelm@duq.edu

Additional Author (s):
Monank Patel
Derek Bremmer

Purpose: Hematologic malignancies, especially acute myeloid leukemia (AML) are associated with a higher incidence of invasive fungal infections, largely due to the prolonged duration of neutropenia during induction chemotherapy. Posaconazole and voriconazole are the most commonly prescribed agents for antifungal prophylaxis at our center. Posaconazole delayed release (DR) tablets claim to have no restrictions on fasting/fed state while also requiring little if any drug concentration monitoring, which was a major limitation of the suspension formulation of posaconazole. The goal of this assessment was to add to the limited pharmacokinetic data available for oral posaconazole DR and voriconazole during AML induction chemotherapy.

Methods: This single center retrospective cohort included all AML patients receiving induction chemotherapy at West Penn Hospital from October 2013 – June 2016 who received antifungal prophylaxis with either posaconazole ER or voriconazole. Patients were identified from the hospitals electronic medical record based on induction chemotherapy regimen of 7 plus 3 (cytarabine plus idarubicin). Patients were excluded if they did not receive induction-based chemotherapy or if they did not receive antifungal prophylaxis with posaconazole or voriconazole with a subsequent serum trough concentration. The following data was collected: patient demographics, choice of antifungal prophylaxis, the loading and maintenance doses of antifungal agents, patients' serum trough concentrations of posaconazole or voriconazole, and the number of days of antifungal prophylaxis the patient received prior to trough concentration. The primary outcome of this study was to compare the rates of therapeutic serum trough concentrations among patients on posaconazole DR and voriconazole tablets. Therapeutic posaconazole and voriconazole trough serum concentrations were defined as greater than or equal to 0.7 mcg/mL and 1–5 mcg/mL, respectively. An elevated Posaconazole

concentration was not defined due to the lack of correlation with toxicity in the literature. Fisher's exact test and descriptive statistics were used to describe nominal data and patient characteristics, respectively. Linear regression was used to correlate patient weight with serum concentration. This study was approved by the West Penn Hospital institutional review board.

Results: A total of 38 patients, 23 posaconazole DR and 15 voriconazole, were included. 32 (62.7percent) were male with a mean height of 170.55 centimeters, weight of 90.76 kilograms, and body mass index (BMI) of 31.23 kg/meters squared. All posaconazole DR patients received a loading dose of 300mg twice daily for 2 doses followed by 300mg daily. Most voriconazole patients (13/15) received a dose of 200mg twice daily without a loading dose. Patients received an average of 5.58 days of antifungal prophylaxis prior to serum trough concentrations. The mean serum trough concentrations of posaconazole DR and voriconazole were 1.1mcg/mL and 3.4mcg/mL, respectively. There was a higher percent of patients on posaconazole that had therapeutic concentrations compared to voriconazole, however not statistically significant (87 vs. 60 percent; p equals 0.12). By linear regression, weight did not correlate well with posaconazole or voriconazole trough concentrations with a R squared value of 0.05 and 0.01, respectively. Nevertheless, 67 percent (2/3) of patients with sub-therapeutic posaconazole concentrations weighed greater than 150kg. In the voriconazole group, 2 (11.8 percent) and 4 (26.7 percent) patients had troughs less than 1mcg/mL and greater than 5mcg/mL, respectively. However, patient weight did not appear to be associated with voriconazole troughs.

Conclusion: Based on these results, posaconazole DR tablets were associated with higher rates of therapeutic concentrations than voriconazole (87 vs. 60 percent). Therefore, therapeutic drug monitoring for posaconazole DR may not be necessary for most patients. However, morbidly obese patients may benefit from therapeutic drug monitoring as 67 percent of sub-therapeutic posaconazole patients weighed greater than 150kg. The majority of non-therapeutic voriconazole troughs were supra-therapeutic and patients' dosages were reduced without adverse effects. We would recommend therapeutic drug monitoring to prevent adverse effects associated with voriconazole. Further research is needed to see if these trends continue among a larger AML population.

Session-Board Number: 2-234

Poster Title: The association between MELD-Na and clinical outcomes in patients with cirrhosis hospitalized with spontaneous bacterial peritonitis

Primary Author: Caitlin McHugh, Duquesne University Mylan School of Pharmacy, Pennsylvania; **Email:** caitlinmchugh6@gmail.com

Additional Author (s):
Brandon Taylor
Gregory Caspero
Michael Steffes
Mehdi Hedjazi

Purpose: Spontaneous bacterial peritonitis (SBP) is the most common bacterial infection in patients with cirrhosis, associated with an estimated 30 percent mortality rate. The MELD (Model for End-stage Liver Disease) provides a severity/prognostic index informing on short-term mortality in patients with cirrhosis. The goal of this project was to evaluate clinical outcomes during hospitalization for SBP using the updated MELD score, which now includes serum sodium as a prognostic factor (MELD-Na).

Methods: The present study was a retrospective chart review that included hospitalized patients treated with antibiotics for diagnosed/suspected SBP between 2009-2014. Data was extracted from the health system electronic medical record using International Classification of Disease 9 –Clinical Modification (ICD-9 CM) coding for cirrhosis (571.2, 5, 6) and SBP (567.23). Data collected included relevant demographics, laboratory markers, treatment and selected clinical outcomes (length of stay, ICU admissions and mortality). SBP diagnoses were considered confirmed if the patient had either a PMN count greater than or equal to 250 cells/mm3, or presence of bacteria in the ascitic fluid; other patients were considered to have suspected SBP if they received empiric treatment during admission for SBP. Both MELD and MELD-Na scores were calculated to assess disease severity and stratified into established categories. MELD-Na scores were calculated according to Organ Procurement and Transplantation Network/United Network for Organ Sharing (OPTN/UNOS) criteria with a score range of 11-40; for MELD-Na scores less than 11, the MELD score was substituted for analysis. Clinical outcomes of interest included length of hospital stay, length of intensive care unit (ICU) stay and in-hospital

mortality. This study was approved by Duquesne University and University of Pittsburgh Medical Center institutional review boards.

Results: A total of 251 patients were included in this study. Of these patients, 182 (72.5 percent) had a confirmed diagnosis of SBP and 69 (27.5 percent) were empirically treated based on a suspicion of SBP. All 251 patients received empiric/targeted antibiotic therapy throughout the duration of their hospital stay. Patients were predominantly male (69 percent), Caucasian (92 percent), and had alcoholic cirrhosis (54 percent). The most common bacteria found in ascitic fluid cultures of confirmed SBP patients were S.aureus (39 percent), E.coli (31 percent), and S.virdians (18 percent). Among all patients, 36 percent were treated with cefotaxime, 17 percent with ceftriaxone, and 16 percent with piperacillin/tazobactam. Overall in-hospital mortality was 11 percent with an average length of stay of 11.5 days (standard deviation [SD] ±11). Average length of hospital stay was consistent among our patient groups, regardless of MELD-Na score. A total of 37 percent of patients required ICU admission, with a mean stay of 8.2 days (SD ±8.8). A disproportionately high mortality (50 percent) and incidence of ICU admission (68 percent) occurred in patients with MELD-Na scores greater than 30.

Conclusion: In our study, patients with SBP and higher MELD-Na scores had a higher risk of being admitted to the ICU as well an increased mortality. This contributes to the field of knowledge that MELD-Na scores can serve as a predictive outcome indicator in patients with cirrhosis that develop SBP.

Poster Title: Revisits to the emergency department for community-acquired pneumonia: a four year experience

Primary Author: Colton Collier, Duquesne University Mylan School of Pharmacy, Pennsylvania; **Email:** colton.collier@gmail.com

Additional Author (s):
Lauren Curry
Samantha Heller
Michaela Palermo
Lauren Zarger

Purpose: Community-acquired pneumonia (CAP) commonly presents to the emergency department (ED). For patients able to be discharged from the ED, current guidelines suggest treatment with a course of macrolide-only therapy, or use of either (1) macrolide plus a beta-lactam, or (2) a respiratory fluoroquinolone if the local resistance rate of Streptococcus pneumoniae to macrolides is greater than 25 percent. The purpose of this project was to determine the relationship between 30-day revisit rates of patients discharged from the ED with CAP according to antibiotic selection, with specific focus on trends pre- and post-treatment protocol implementation at an urban medical center.

Methods: A retrospective single center cohort study using data collected through chart review of adult patients with ED visits for CAP was conducted on two temporal cohorts: 2012-2013 and 2014-15. At the beginning of 2014, our institution's CAP empiric antibiotic protocol changed to reflect increasing resistance to macrolides. Azithromycin plus cefuroxime was recommended as a first line option and a respiratory fluoroquinolone as second line therapy for patients with a beta-lactam or macrolide allergy. In order to determine prescribers' compliance and to see if there was a clinical effect on the return rate following protocol implementation, the following data was collected: patient demographics, clinical characteristics (CURB-65 [confusion, urea, respiration, blood pressure, age] scoring and Charlson Comorbidity Index [CCI]), antibiotic therapies received at discharge, and if the patient revisited any ED in the healthcare system within 30 days due to worsening pneumonia or other causes. Exclusion criteria included patients who received antibiotics prior to coming to the ED, patients less than 18 years of age,

and patients who were admitted to the hospital from the ED. Descriptive statistics were utilized for patient characteristics, and Chi-square analyses were used to compare differences in return rates between treatment groups and characteristics between cohorts. This study was approved by Duquesne University and University of Pittsburgh Medical Center institutional review boards.

Results: A total of 741 patients were included in the study from 2012-2015 (411 patients during 2012-13 and 330 patients during 2014-15). Compared to the 2012-13 cohort, patients treated in 2014-15 had lower CURB-65 scores but higher CCI. The proportion of patients receiving macrolide monotherapy decreased from 70.1% to 42.7% between the two cohorts, with increases in utilization seen for macrolide/beta-lactam combination therapy (6.3% to 21.8%) and fluoroquinolones (15.1% to 23.6%). Revisit rates to the ED due to both general causes and worsening pneumonia were numerically higher in 2014-15 compared to 2012-1013, with a statistically significant increase in overall revisit rate for patients treated with fluoroquinolones (14.5% to 29.5%).

Conclusion: A significant decrease in macrolide monotherapy with a reciprocal increase in both macrolide/beta-lactam combination and respiratory fluoroquinolone monotherapy was observed in the two temporal cohorts, as anticipated due to the change in hospital protocol. There was no significant change in ED revisit rates due to worsening pneumonia between the two cohorts suggesting no difference in efficacy despite current guideline's recommendations. Larger prospective studies are needed though to validate this data and assess the current guideline recommendation of combination use of macrolide and beta-lactam or respiratory quinolone when a >25% resistance rate to Streptococcus pneumoniae is present.

Session-Board Number: 2-236

Poster Title: Clinical Use and Outcomes of Non-acetaminophen Acute Liver Failure Treated with N-acetylcysteine at a Academic Tertiary Care Center

Primary Author: Hannah Cawoski, Duquesne University Mylan School of Pharmacy, Pennsylvania; **Email:** cawoskih@duq.edu

Additional Author (s):
Megan Jackson
Hannah Mazur
Lauren Finoli

Purpose: N-acetylcysteine is the first line treatment for patients with acetaminophen toxicity due to accidental or intentional overdose. In patients with toxic serum levels of acetaminophen, the use of N-acetylcysteine has shown to improve overall health outcomes, particularly an improvement in patients' liver function. N-acetylcysteine eliminates the toxic amounts of acetaminophen metabolite through a known mechanism, however, may also improve the health outcomes of patients with non-acetaminophen induced acute liver failure according to more recent literature. Therefore, the purpose of this study was to determine prescribing practices as well as clinical efficacy markers for N-acetylcysteine at a tertiary care center.

Methods: The Allegheny General Hospital IRB approved this retrospective medication use evaluation which analyzed patients who presented with non-acetaminophen related acute liver failure that were treated with N-acetylcysteine. Outcomes assessed included describing dosing prescribing practices given varying doses studied in the literature, improvement in laboratory values commonly monitored in the clinical scenario of acute liver failure (AST, ALT, bilirubin levels, Alk Phos, INR), and analysis of cost associated with varying dosage strategies. Patients 18-89 years of age who presented with documented acute liver failure as a primary diagnosis and negative acetaminophen levels on presentation were included. Patients were excluded if they were prescribed N-acetylcysteine for the treatment of acetaminophen toxicity, had documented active liver malignancy, pregnant patients, and prisoners.

Results: A total of 23 patients were admitted between January 1, 2015 and May 2016 that were treated with n-acetylcysteine for non-acetaminophen induced acute liver failure. Of these patients, all were treated with conventional dosing strategies indicated for acetaminophen toxicity. Mean baseline laboratory values for the cohort included AST of 2993.6 units/L, ALT of 1467.5 units/L, INR of 2.8, and alkaline phosphatase of 131.5 units/L. Laboratory values trended down in the cohort at 24, 48 and 72 hours after n-acetylcysteine administration. At 72 hours, the mean AST value was 936.9 units/L, mean ALT was 1043.6 units/L, INR of 2.7, and alkaline phosphatase of 130.3 units/L.

Conclusion: Prescribers preferentially used dosing strategies indicated for acetaminophen toxicity in patients presenting with non-acetaminophen acute liver failure, which was influenced by easily accessible ordersets within the organizations CPOE. Additionally, laboratory values, including AST, ALT, alkaline phosphatase, and INR decreased at 24, 48, and 72 hours after n-acetylcysteine administration, possibly justifying its use in this patient population in addition to other published literature on the subject.

Submission Category: Cardiology/ Anticoagulation

Submission Type: Evaluative Study

Poster Title: Effect of intravenous versus enteral acetaminophen on opioid usage after cardiothoracic surgery

Primary Author: Marissa Romanish, Duquesne University Mylan School of Pharmacy, Pennsylvania; **Email:** romanishm@duq.edu

Additional Author (s):
Jesse Dorchak
Timothy Heiss
Savas Mavridis
Luis Gonzalez

Purpose: The high cost and limited evidence of effectiveness of intravenous (IV) acetaminophen in comparison to enteral acetaminophen products has brought the value of IV acetaminophen into question. The purpose of this study is to evaluate the opioid-sparing effects of IV compared to enteral acetaminophen in postoperative cardiothoracic (CT) surgery patients. We hypothesize that IV in comparison to enteral acetaminophen will produce no difference in total morphine equivalents used in postoperative CT patients who are receiving either IV or enteral acetaminophen. Antiemetic usage will be evaluated as a secondary endpoint.

Methods: The study was conducted at Conemaugh Memorial Medical Center. This quasi-experimental study consisted of retrospective data collected from two cohorts of patients. The first group included subjects undergoing CT surgery from January to August 2016 who received 3 doses of IV acetaminophen 1 gram every six hours after surgery. The comparison group included subjects receiving enteral acetaminophen 1 gram every six hours for 3 doses postoperatively. The same demographic and data variables were collected for both groups. Data variables collected from the subjects included non-opioid pain medications usage, opioid usage, antiemetic usage and home opioid usage. Data collection began at the conclusion of surgery, which was termed day 0, and ended at the first post-operation day, which was termed day 1. This study received institutional review board approval from Conemaugh Memorial Medical Center who waived the need for informed consent since this was a planned practice change by the cardiothoracic surgery service. A t-test with 95 percent confidence intervals was used to compare the outcomes of each cohort.

Results: Data were collected for a total of 101 subjects. 84 subjects were in the IV acetaminophen group and 17 subjects were in the enteral acetaminophen group with the mean age of all patients being 70 years old. The mean total IV morphine equivalents usage was 17.4 mg and 21.0 mg for the IV and enteral acetaminophen groups, respectively (p equals 0.38). The mean ondansetron usage was 4.5 mg for the IV acetaminophen group and 6.4 mg for the enteral acetaminophen group (p equals 0.28). A select number of patients received additional antiemetic coverage, but the number of patients was not enough to warrant exclusion from the study. The mean total acetaminophen usage was 1377 mg and 3794 mg for the IV and enteral acetaminophen groups, respectively. Patients in the enteral acetaminophen group received significantly higher amounts of acetaminophen than the IV acetaminophen group (p less than 0.01).

Conclusion: Although IV acetaminophen has been suggested to provide greater efficacy than enteral acetaminophen for as needed use, no difference was found for morphine equivalents when both are administered as a background. Patients in the enteral acetaminophen group received a greater amount of acetaminophen, but less than 4 grams in 24 hours. Enteral compared to IV acetaminophen is a cost-effective adjunctive pain management strategy in patients undergoing CT surgery.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Descriptive Report

Poster Title: Use of barcode scanning technology during automated medication dispensing cabinet (AMDC) restocking and its effect on medication safety: A one year assessment.

Primary Author: Dennis Goodstein, Duquesne University Mylan School of Pharmacy, Pennsylvania; **Email:** dengoodstein@gmail.com

Additional Author (s):
Laura Reilly

Purpose: Accurate restocking of medications into the AMDC is a crucial component for meeting hospitals' medication safety standards. Automated restocking via the use of barcode technology was identified as way to reduce the risk of restocking errors and overall medication errors. This project was designed to evaluate the role that barcode scanning technology plays in reducing medication errors that result from the incorrect stocking of medications into an AMDCs. In addition, technician feedback, usage statistics, and medication refilling workflow and procedure were evaluated.

Methods: On July 27th, 2015 a "scan on restock" protocol was implemented at St. Clair Memorial Hospital in an effort to reduce medication restocking errors. Training sessions were directed and held during the first month of implementation for all technicians. Medication restocking errors and occurrence reports were reviewed and analyzed over a 12 month period leading up to initiation of the barcode scanning protocol and 12 months following implementation. When reviewing each restocking error recorded, several factors were taken into account including: if barcode scanning was used to restock the medication, if the medication being restocked was able to be scanned, and if the automated dispensing cabinet had scanning capabilities (cabinets located in operating rooms did not have the ability to use barcode scanning technology). Usage statistics were also analyzed for individual technicians and on each individual unit. In addition, a survey was sent to all technicians that assessed overall adherence to "scan on restock" protocol, efficacy of protocol in reducing restocking errors, ease of use, restocking speed with use, current restocking procedure, efficacy of protocol, and suggestions on how to improve the current process. Completion of the survey was optional and it was made available to all technicians and interns on the pharmacy staff at the time of presentation.

Results: The total number of reported restocking errors from July 1st, 2014 through July 27th, 2015 was 9 out of 34334 total restocks. Following implementation of barcode scanning technology on July 27th, 2015 the total number of errors reported over the next 12 months was 3 out of 34334 total restocks. The P-value was < 0.0001, therefore the reduction in error was found to be statistically significant. There was a sixty-seven percent reduction in medication restocking errors 12 months after initiation compared with 12 months prior to initiation. Of these 3 reported medication refill errors, it was shown that on all three occurrences the new "scan on restock" protocol was not utilized by the technician restocking the cabinet. Twenty one pharmacy technicians participated in the survey. Ninety five percent of technicians said that they utilize the barcode scanning when possible. Sixty-two percent of technicians stated that the new scanning protocol only "sometimes" reduced the time spent restocking. Thirty-three percent stated that the new protocol "always" reduces the time spent restocking. The median and mode of the comfort level with the scanning protocol on a scale of one to five were 5 and 5 respectively.

Conclusion: Implementation of barcode scanning technology when restocking AMDC has successfully reduced the risk of medication restocking errors. Medication restocking errors dropped 67% in 12 months following implementation compared to 12 months prior. All of the post-intervention errors reported occurred on products that were not scanned during restocking. The majority of technicians followed the scan on restock protocol and felt the process helped to reduce errors. Technicians believed that "scan on restock" is more time consuming. Future plans for advancement with "scan on restock" include placing barcodes on all IV products compounded to make them compatible with the current restocking procedure.

Poster Title: Investigation of the therapeutic potential of N-acetyl cysteine and the tools used to define nigrostriatal degeneration in vivo

Primary Author: Jimin Han, Duquesne University Mylan School of Pharmacy, Pennsylvania; **Email:** hanj@duq.edu

Additional Author (s):
Negin Nouraei
Lauren Zarger
Justin Weilnau
Daniel Mason

Purpose: N-acetyl cysteine (NAC) is a glutathione precursor molecule used to treat acetaminophen overdose and has shown potential in treating neurodegenerative diseases such as traumatic brain injury caused by explosives in veterans, and patients of Alzheimer's to a lesser extent. In this study, the therapeutic potential of NAC was investigated in an animal model utilizing a toxicant compound 6-hydroxy dopamine (6-OHDA) to mimic the loss of dopaminergic neurons at the nigrostriatal pathway seen in Parkinson's disease.

Methods: Animals were infused intrastriatally with either the oxidative neurotoxicant 6-OHDA (4 mcg) or an equal volume of vehicle. NAC or an equal volume of vehicle was administered intraperitoneally (100 mg/kg) immediately after the infusion of 6-OHDA for either 10 or 21 days. Tyrosine hydroxylase (TH) was used as the dopaminergic marker in the nigrostriatal pathway made up of the striatum and substantia nigra. As TH expression is affected by stress, the tracer FluoroGold (FG) was injected into the striatum one week prior to 6-OHDA infusions to label nigrostriatal neurons retrogradely. All animals received 0.015 mg/kg buprenorphine subcutaneously during recovery from surgery and antibiotic treatment of their scalp wound. Brain sections of these animals were mounted onto glass slides and scanned on an infrared Odyssey Imager for lower resolution analysis or under epifluorescent microscopy (Olympus) for higher resolution analysis. A blinded observer made infrared measurements of TH levels by tracing regions of interest (ROIs), while bilateral TH+ cell counts of the substantia nigra were made from the images stitched on the Olympus microscope. Two independent raters counted nigral cells on select sections and the results were found to be in agreement. Finally, sections

from FluoroGold-infused animals were viewed under confocal microscopy to assess colocalization of FluoroGold with TH.

Results: Four measures were taken to analyze the protective effects of NAC: striatal TH levels, nigral TH levels, nigral TH+ cell counts, and nigral FuoroGold levels. As expected, nigral FG staining and cell counts of FluoroGold+ profiles were both more sensitive measures of nigrostriatal degeneration than measurements relying on TH alone. After 10 days of injections, it was found that there was a significant increase of TH in the striatum, both in terms of overall expression and density, while the protection was muted in the substantia nigra. However, after 3 weeks of injection, NAC failed to show protection against the oxidative toxicity of 6-OHDA in both the striatum and substantia nigra.

Conclusion: NAC may offer protective effects against oxidative toxicity only transiently. When concerning a chronic disease such as Parkinson's, it is important to not only examine the short-term effects, but also the long-term effects of treatment agents as well. Accordingly, it would be imperative that future studies extend the timeline so that the results are more meaningful and relevant to the disease state.

Submission Type: Descriptive Report

Session-Board Number: 2-240

Poster Title: Impact of clinical pharmacy involvement on the management of hypertension and diabetes: a closer look at clinical outcomes and medication-related problems

Primary Author: Jenna Fancher, Jefferson College of Pharmacy, Pennsylvania; **Email:** jenna.fancher@jefferson.edu

Additional Author (s):
Anuja Kanaskar
Leon Sakkal
Kimberly Carter
Nicholas Leon

Purpose: According to the Centers for Disease Control and Prevention, 33.5% of adults in the United States have hypertension and 9.3% have diabetes. In 2012, healthcare costs exceeded $200 billion as a result of improper medication use. A major barrier to preventing and managing chronic conditions is the shortage of primary care providers, which necessitates the use of non-physician providers. The purpose of this study was to evaluate the clinical impact of two ambulatory care pharmacist faculty members and their advanced pharmacy practice experience (APPE) student-pharmacists on the management of patients with diabetes and/or hypertension in an outpatient primary care office.

Methods: Two pharmacist faculty members with advanced, specialized training in ambulatory care have spent approximately 30% of their time precepting APPE student-pharmacists while providing high-level clinical services for over five years. The practice site is a large, outpatient internal medicine primary care office within a large university medical center that is located in a socioeconomically depressed area of a large metropolitan area. This site serves as a primary teaching site for internal medicine medical residents who are accepted into a primary care track of their residency. This retrospective chart review included adult patients aged 18 years or older diagnosed with diabetes and/or hypertension who had their first visit with pharmacy between January 2014 and May 2016. Patients were excluded if they were scheduled to see pharmacy for reasons other than hypertension and/or diabetes, if they only had one visit with pharmacy in the past year, and if the initial visit with pharmacy was before January 1, 2014. Patient-specific data collected via retrospective chart review included demographic

information, baseline measurements (blood pressure and/or hemoglobin A1c), dates of initial and final pharmacy visits, type and number of clinical interventions made by the pharmacist to optimize disease-state management, and follow-up measurements (blood pressure and/or hemoglobin A1c at follow-up appointments). Clinical interventions were retrospectively classified according to a type of medication-related problem identified in the original SOAP note.

Results: For data collected during the study period, 646 patients were screened and 116 patients met the inclusion criteria. Patient demographics included 47% males and 53% females with an average age of 59 years (± 13.1). These patients were predominantly African American (75%), had an average of five chronic conditions (± 2.4), and were on seven medications (± 4.0) at the initial pharmacy visit. For diabetes management, a total of 533 interventions were made during the study period. The majority of these interventions were categorized as addressing diet and exercise counseling (35%), disease-state management (25%), and medication effectiveness (15%). By the first follow-up visit, the median baseline hemoglobin A1c decreased by 1.6%. This hemoglobin A1c reduction was maintained by subsequent follow-up visits, with a median hemoglobin A1c of 7% by the fourth follow-up visit. For the management of hypertension, 278 total interventions were made during the study period with the majority being categorized as addressing diet and exercise counseling (37%), disease-state management (15%), and adherence (14%). The initial median blood pressure was reduced throughout the study period with the largest effect on the systolic blood pressure, which was reduced by 4 mmHg.

Conclusion: During the study period, pharmacist involvement in the management of diabetes and hypertension lead to clinically significant improvement in clinical outcomes for diabetes according to the reduction in hemoglobin A1c and borderline clinically significant improvement in hypertension based on slight reduction in systolic blood pressure. There was a total of 811 interventions made by pharmacy during the study period for diabetes and hypertension visits combined, with an overwhelming majority including diet and exercise counseling, medication effectiveness, and disease-state management. This study suggests that pharmacist involvement in the management of diabetes and hypertension may lead to improved clinical outcomes.

Poster Title: Implementing a pharmacist-led, Individualized Medication Assessment and Planning (iMAP) program to improve medication use in ambulatory senior adult oncology patients

Primary Author: Shannon Doherty, Jefferson College of Pharmacy, Pennsylvania; **Email:** shannon.doherty@jefferson.edu

Additional Author (s):
Elizabeth Pigott
Margaret Wang
Emily Hajjar
Ginah Nightingale

Purpose: Medication-related problems (MRP) is a significant healthcare issue and accounts for $177 billion in medication-related morbidity and mortality. One approach to address MRP and optimize medication management is through utilization of pharmacists as part of the healthcare delivery model for interprofessional, team-based care.
The objectives of the pharmacist-led iMAP intervention pilot were to: examine the feasibility of the iMAP intervention, compare the number and rate of MRP between patient follow-up sessions [Day 0, 30, 60], and evaluate the proportion of MRP that are successfully addressed between follow-up sessions.

Methods: This was a prospective, exploratory, IRB approved study conducted at the Senior Adult Oncology (SAO) Center at Thomas Jefferson University. All ambulatory, English speaking patients aged at least 65 years who received a comprehensive geriatric-oncology assessment between June 2014 and October 2015 were eligible to participate. Patients brought in all their medications (prescription, non-prescription, and complementary and alternative) for the pharmacist-led assessment. The study was facilitated by two Advanced Practice Pharmacists and the follow-up sessions were conducted via telephone at 30 and 60 days post the initial face-to-face session. Identified MRP and recommendations were communicated to the patient, the SAO team, and forwarded to the primary provider. All planned statistical analysis was conducted using SAS version 9.3.

Results: Baseline demographics of 41 patients include a mean age of 79.1 years; 66% women, mean number of comorbidities was 7.76 excluding primary cancer, and the most prevalent malignancies were lymphoma, breast cancer and colorectal cancer. The mean number of medications used was 10.44 at baseline. The mean number of prescription medications was 6.7, 3.15 non-prescription, and 0.59 herbal medications. There was a total of 123 MRP with a mean of 3 per patient. The most common MRP categories were suboptimal drug use (i.e. no indication for drug therapy, safer medication alternatives), medication under-treatment and suboptimal medication dosing. There were 46% of the pharmacist recommendations that were accepted by the primary provider and/or the patient by the end of the 60-day follow-up period. The overall number of MRP was decreased by 45.5%, and number of patients with MRP decreased by 20.5%. The mean number of MRP per patient was significantly reduced from 3 to 1.6. The average time requirement to conduct the initial session was 22 minutes and 15 minutes for the follow-up phone sessions. Resources needed to conduct the iMAP intervention include a tracking system for scheduling follow-up calls and a database for tracking acceptance of recommendations.

Conclusion: In an effort to reduce MRP in the senior adult oncology population, the iMAP intervention was designed to assess the impact pharmacists can have in reducing these incidences. The iMAP model has the potential to address a significant and timely issue affecting senior adults: the burden of continuously managing and monitoring multiple medications.

Poster Title: Evaluation of antimicrobial initiation and selection prior to a newly implemented microbial identification system

Primary Author: Deirdre Yarosh, Jefferson College of Pharmacy, Thomas Jefferson University, Pennsylvania; **Email:** daw007@jefferson.edu

Additional Author (s):
Kevin Farrow
Anna Drapkin
Sareen Vartanian

Purpose: The utilization of innovative techniques, such as matrix-assisted laser desorption ionization time-of-flight mass spectrometry (MALDI TOF MS), for microbial identification and susceptibilities has the potential to greatly reduce pathogen identification time from days to minutes on the same day bacterial colonies are cultured. By both ensuring the pathogen isolated is covered by the antibiotics selected and ensuring that therapy is narrowed or discontinued in a timely manner, MALDI TOF MS can reduce the time to appropriate antibiotic treatment. MALDI TOF MS will be implemented at Abington Hospital, but in order to better evaluate its impact, retrospective pre-intervention data was collected.

Methods: Following institutional review board approval, all patients admitted to the hospital from January through February 2016 with positive blood cultures were included in this evaluation. Information retrospectively collected from patient charts included microorganism identification and susceptibilities, presumed source of infection, times of cultures, susceptibility reporting, antibiotic initiation, initial empiric therapy, and final appropriate regimen. Patients were excluded from the analysis if data was missing for the timing of antibiotic therapy. The primary endpoint was time to appropriate therapy, which was determined based on the average time to streamline therapy, average time to broaden therapy, and average time to therapy discontinuation. Secondary endpoints included time to microorganism identification, time to susceptibility information, and length of time on inappropriate therapy. This data, representing part one of the study, is based on the currently utilized Vitek microbial identification system. In the coming months, Abington Hospital will implement the MALDI TOF

MS system. The results reported here will be compared to the results after implementation of MALDI TOF MS to determine the effect on antimicrobial stewardship.

Results: Twenty four patients were included in the final analysis, of those, fifteen were eligible for a change in treatment. Among the patients who were streamlined (n=13), the average time to therapy streamlining was 3 days, 18 hours, and 36 minutes. For patients who had therapy broadened (n=1) the average time to therapy change was 2 days, 20 hours, and 40 minutes. In patients requiring therapy discontinuation (n=1), the average time to therapy discontinuation was 3 days, 19 hours, and 54 minutes.

Conclusion: Based on the results collected, we anticipate the time to therapy optimization with utilization of MALDI TOF MS will be reduced.

Submission Type: Evaluative Study

Session-Board Number: 2-243

Poster Title: Retrospective evaluation of fall admissions in geriatric patients

Primary Author: Dalton Fishel, Lake Erie College of Osteopathic Medicine - Erie Campus, Pennsylvania; **Email:** dalton.fishel@rx.lecom.edu

Additional Author (s):
Michael Makaimoku
Kristen Gawronski

Purpose: The CDC Injury Center has stated that the number of fatal falls in older adults is estimated to reach 100,000 per year by 2030, with an associated cost of 100 billion dollars. Previous studies have closely associated selective serotonin/norepinephrine reuptake inhibitor (SSRI/SNRI) use to an increased risk of falls in elderly persons. The purpose of this evaluation was to evaluate 30-day readmission in a cohort of geriatric patients receiving SSRIs or SNRIs to determine if they were at an increased fall risk compared to geriatric patients not receiving those medications.

Methods: The study was a retrospective chart review of patients ages 65 years and older admitted to a community hospital in Erie, PA for a fall-related injury between January 1, 2007 and April 27, 2016. The primary study objective was to evaluate recurrent 30-day fall rate in patients who were prescribed SSRIs or SNRIs compared to those not receiving those medications. The study was approved by the Institutional Review Board.
A computerized list of patients was generated based on ICD-9 codes. Exclusion criteria included patients with incomplete medical records. We examined previously identified risk factors that may be associated with an increased fall risk. Risk factors included: common medical causes for falls such as blindness, seizures, concussion, SIADH, hypoglycemia, peripheral neuropathy, and hyponatremia. Sodium levels were obtained to identify potential fall risk. For the purposes of our study, hyponatremia was defined as mild (130-135 mEq/L), moderate (120-129 mEq/L) and severe (less than 120 mEq/L). Information on medications associated with an increased fall risk were obtained. These classes were identified based on the Beers' List criteria and from the "Meta-analysis of the impact of 9 Medication Classes on Falls in Elderly Persons". Demographic data, including overall comorbidity defined by the Charlson Score, was obtained.

Results: We identified 157 patients from our computerized list. 67 were included in the SSRI/SNRI group and 90 patients to the non-SSRI/SNRI group. The SSRI/SNRI group was younger (81.3 vs 84.7; p = 0.01), had improved renal function (CrCl (ml/min) 51 vs 43; p = 0.04), and had more baseline comorbidities defined by the Charlson Score (2.8 vs 2.2; p = 0.04). All other baseline characteristics were not significantly different.

There was no statistically significant difference in the incidence of fall-related readmission within 30 days between groups (0 vs 1; p = NS). Hospital length of stay was also not statistically different (7.6 vs 7.8; p = NS). Of interest, the average patient was on at least five medications with a known risk to potentiate falls in the elderly.

Conclusion: SSRI or SNRI use in geriatric patients does not appear to be associated with an increased risk of a fall-related readmissions. Limitations include the small sample size and retrospective nature of the study. Geriatric patients who were included in our study were taking on average five medications which have been proven to increase falls, with antihypertensives being the most commonly prescribed medications. Further studies could be designed with a larger patient population to evaluate whether the results of this study are valid or the result of a lack of power.

Submission Category: General Clinical Practice

Submission Type: Case Report

Session-Board Number: 2-244

Poster Title: Warfarin resistance with patients receiving enteral tube feeding

Primary Author: Shivam Patel, Lake Erie College of Osteopathic Medicine School of Pharmacy, Pennsylvania; **Email:** shivam.patel@rx.lecom.edu

Additional Author (s):
Sarah Dombrowski
Michelle Hiles

Purpose: A few studies and case reports have examined warfarin administration with enteral tube feeding, however, this interaction is not widely publicized. The interaction of concern involves vitamin K in enteral feeds and its effects on efficacy of warfarin leading to resistance. Initial case reports of warfarin resistance date back to before the 1980s when vitamin K concentrations in enteral feeding products were above the recommended daily allowance. Since that time period, manufacturers have reduced the concentration to less than the United States recommended daily allowance. Additionally, in-vitro analyses have shown warfarin binding to proteins and macromolecules in enteral feeding products.

A 71 year old male presents to the emergency department in a community hospital with unilateral knee/lower leg swelling. Patient denied any fever, nausea, vomiting or chills. His past medical history included coronary artery disease, hypertension, hyperlipidemia, and myocardial infarction. Due to previous history, patient was admitted for further evaluation. Patient was on warfarin 2mg daily at home. A few days after the patient was admitted, an enteral feeding product was started and continued for 4 days. During that 4 day time period, on day 1 of enteral feeding the patient was on warfarin 2.5mg with an international normalized ratio (INR) of 2.2. Day 2, the patient was on warfarin 2mg with INR of 2.0. Day 3, patient was on warfarin 2mg with INR of 1.7. On day 4, patient was on warfarin 4mg with an INR of 1.4. The INR remained low at 1.5 on day 5 where the patient received 4mg of warfarin. Even with the increase in warfarin dose throughout enteral feeding, the INR remained subtherapeutic.

As with previous case reports, this case report suggests warfarin resistance due to involvement of enteral feeding products. Currently there are no standardized recommendations on whether to withhold enteral feeding while administering warfarin. It may be necessary to monitor INR and titrate warfarin dose to a therapeutic range in otherwise stable patient while receiving enteral feeding. Further research and evaluation of warfarin resistance with enteral tube

feeding will provide guidance to help solve the issue. Additionally, hospitals could consider instituting a protocol for anti-coagulation management throughout enteral feedings.

Poster Title: Increase in serum creatinine following the initiation of cobicistat or dolutegravir containing antiretroviral regimens

Primary Author: Ryan Greenley, Philadelphia College of Pharmacy, Pennsylvania; **Email:** rgreenley@mail.usciences.edu

Additional Author (s):
Jessica Adams

Purpose: Cobicistat, a pharmacokinetic booster, and dolutegravir, an antiretroviral, are used in combination therapy for the treatment of human immunodeficiency virus (HIV). In clinical trials, both agents were associated with an increase in serum creatinine (SCr) within the first 8 weeks due to inhibition of renal transporters associated with renal tubule secretion. The purpose of this study was to determine whether patients in a real world setting, who initiated cobicistat or dolutegravir, experienced a SCr increase comparable with the 0.1 to 0.2 mg/dL median increase seen in clinical trials.

Methods: This retrospective chart review was approved by the institutional review board at Cooper University Hospital. All HIV infected adult patients that had been initiated on a cobicistat or dolutegravir containing antiretroviral regimen between August 1, 2012 and May 1, 2016 were included. Patients younger than 18 years of age and pregnant women were excluded. Subjects' SCr concentrations were recorded from the electronic medical record prior to initiation and at each clinic follow-up visit. Additional subject data collected included HIV-1 RNA viral load, CD4 cell count, concomitant nephrotoxic agents and concomitant inhibitors of renal transporters. The primary outcome measure was the change in SCr from baseline to the first follow-up after at least 8 weeks of treatment. Secondary outcomes included change in creatinine clearance from baseline to the first follow-up after 8 weeks of treatment, time to peak SCr from baseline, and frequency of drug discontinuation due to renal dysfunction. Data was collected for the first 48 weeks on therapy.

Results: A total of 39 patients were included in this analysis. The majority were treatment naïve (56.4 percent), males (69.3 percent) with a median age of 42 years (IQR 30 to 53 years). Of the 39 patients collected, 24 (61.5 percent) started cobicistat containing regimens, 14 (35.9

percent) started dolutegravir containing regimens, and 1 (2.6 percent) started on both. The median change in SCr from baseline to the first follow-up after at least 8 weeks of treatment was 0.07 mg/dL (IQR minus 0.02 to 0.23 mg/dL). A corresponding median change in CrCl from baseline to the first follow-up after at least 8 weeks of treatment was minus 5 mL/min (IQR minus 21 to 1 mL/min). The median time to peak SCr concentrations was 29 weeks (IQR 16 to 59 weeks). A majority of patients remained on their current regimen at the end of the study period (64.1 percent) while only 2 patients discontinued due to renal dysfunction (5.12 percent). Most patients (79.5 percent) were on tenofovir disoproxil fumurate (TDF) containing regimens which is a known nephrotoxic agent. Thirty-eight patients were on concomitant nephrotoxic agents (97.4 percent) and 14 were on concomitant renal transport inhibitors (35.8 percent).

Conclusion: There was an increase in SCr concentrations in patients following initiation of cobicistat or dolutegravir. The 0.07 mg/dL increase in SCr that was observed is similar to the 0.1 to 0.2 mg/dL increase from previous studies despite a real life clinic setting in a patient population with comorbid disease states and concomitant medications. Future directions for this project are to compare the results to a control group and explore the effect of comorbidities and concomitant medications. The control group will consist of patients with HIV initiated on a regimen that did not contain cobicistat or dolutegravir during the study period.

Poster Title: A long-term hospitalization complicated by a pre-vancomycin-intermediate Staphylococcus aureus (pVISA) endocarditis and daptomycin-associated rhabdomyolysis: a case report.

Primary Author: Steven Galerkin, Philadelphia College of Pharmacy, Pennsylvania; **Email:** stevengalerkin@gmail.com

Additional Author (s):
Gul Madison
Thomas Turco
Lynn Kleina

Purpose: This case illustrates the concern of rising vancomycin minimum inhibitory concentrations (MICs) complicated by an adverse effect to alternative therapy. A 56-year-old female with a history of cerebral vascular accident (CVA), Type 2 Diabetes, toxic nodular goiter, deep vein thrombosis (DVT), morbid obesity (BMI>40), and chronic diastolic heart failure is hospitalized for a significant amount of time within a 7-month span.

She initially presents to the hospital with a right diabetic foot infection that requires surgical debridement. The medical team discovers tendonitis without bone involvement. She is empirically treated with IV vancomycin and piperacillin-tazobactam. Her MRI of the foot does not show osteomyelitis. Surgical cultures return positive for methicillin-sensitive Staphylococcus aureus (MSSA) and the patient's antibiotic regimen is modified to a 2-week course of IV ampicillin-sulbactam.

Before the completion of her antibiotic course, she is admitted back to the hospital with shortness of breath and respiratory failure. She is found to have health care-associated pneumonia (HCAP), requiring intubation and mechanical ventilation. During this prolonged hospital stay, the patient's right foot reveals a necrotizing infection, one requiring above-ankle amputation. Shortly after stump closure, the patient is permitted to leave the hospital. Initially, she receives cefepime for HCAP coverage. Her methicillin-resistant Staphylococcus aureus (MRSA) screen is negative. Following culture results, cefepime is changed to piperacillin-tazobactam to cover anaerobic organisms. Antibiotics are adjusted further to meropenem and vancomycin to cover the necrotizing foot infection. Following amputation, the patient receives 10 additional days of antibiotics with linezolid and cefepime. Linezolid had replaced vancomycin

due to fluctuations in kidney function. Operating room (OR) cultures return negative and the patient is discharged.

Two months later, the patient is readmitted with abdominal pain, nausea, and vomiting. She is found to have acute cholecystitis and is started on IV metronidazole and ciprofloxacin. A cholecystostomy tube reveals negative bile cultures. At this time, the patient also begins to show mental status changes in the form of lethargy and confusion, creating suspicion for meningitis. IV vancomycin, piperacillin-tazobactam, and acyclovir are started for expanded coverage. Lumbar punctures are unobtainable due to body habitus and blood cultures return negative. IV tigecycline is added on briefly to cover a suspected UTI with multi-drug resistant (MDR) Acinetobacter baumanii. As the patient's mental status begins improving, all antibiotics are discontinued. The peripherally inserted central catheter (PICC) in the right arm is maintained for ongoing IV requirements.

Several weeks into her admission, she develops new fevers prompting the medical team to send blood cultures. These cultures return positive for MRSA with isolates showing a vancomycin MIC of 1µg/mL. The PICC line is subsequently removed and IV vancomycin is started. Despite adequate vancomycin troughs, the MRSA bacteremia persists. A 2D echocardiogram (ECHO) shows no evidence of valvular vegetation, but a successive transesophageal echocardiography (TEE) confirms mitral valve vegetations, indicating endocarditis. Cardiothoracic surgery evaluates the patient and concludes that she is not a candidate for valve repair surgery due to her numerous comorbidities. The MRSA MICs for vancomycin later rise to 2.0µg/mL, signifying a trend towards vancomycin-intermediate Staphylococcus aureus (VISA). The patient is switched to IV daptomycin due to vancomycin's diminished ability to sterilize the blood. Upon receiving 1 week of therapy with daptomycin, the patient experiences an elevation in creatine phosphokinase (CPK) from 24U/L at baseline to 2559U/L, indicating rhabdomyolysis. Ceftaroline therapy is introduced, replacing daptomycin. Unfortunately, 10 days into therapy, the patient succumbs to her illness. Additional details of this case including antibiotic regimens, cultures and sensitivities, lab values, and general analysis are discussed in the poster presentation.

Poster Title: Readability and length of high-risk informed consent forms

Primary Author: Jonathan Burns, Philadelphia College of Pharmacy, Pennsylvania; **Email:** jburns@mail.usciences.edu

Additional Author (s):
Tracy Ziolek
Karen Tietze

Purpose: The Food and Drug Administration requires informed consents forms to be written in "language understandable to the subject." The average American reads at a 7th or 8th grade level; consent cannot be informed if the subject is unable to understand the document. Prior research analyzed specific types or sections of informed consent forms to quantify the complexity. The purpose of this study was to assess the readability and length of informed consent forms used in high-risk studies.

Methods: This study analyzed informed consent forms for high-risk clinical trials approved in 2014 by a single institution. High-risk trials were defined as Phase I trials, Phase II trials, Phase III investigator-initiated trials, and trials involving vulnerable populations (children, pregnant women, prisoners). Each informed consent form was assessed for page length and readability using the following scales: Flesch-Kincaid Grade Level (FKGL), Simple Measure of Gobbledygook (SMOG), and Flesch Reading Ease (FRE). Analyses were performed using the program Readability Studio (2015 version, Oleander Software, Ltd. Vandalia, OH).

Results: Forty-eight informed consent forms from high-risk studies were analyzed. The mean FKGL was 9.5 plus or minus 0.8 (range 7.1-11.4), indicating a 9th-10th grade education readability. Three (6.3%) of the informed consent forms were written at an 8th grade level or lower. Sixteen (33.3%) of the informed consent forms were written at a 10th grade level or higher. The mean SMOG was 11.7 plus or minus 0.7 (range 9.8-13), indicating an 11th-12th grade education readability. None of the informed consent forms were written at an 8th grade level or lower. Forty-seven (97.9%) of the informed consent forms were written at a 10th grade level or higher. The mean FRE was 55.2 plus or minus 3.6 (range 48-67), indicating the text is "fairly difficult to read." Seven (14.6%) of the informed consent forms were written at

"standard difficulty" or easier. Forty-one (85.4%) of the informed consent forms were written at "fairly difficult" or harder. The mean page length was 20 plus or minus 5.2 pages (range 10-32 pages). None of the informed consent forms were shorter than 10 pages in length. Twenty-six (54.2%) of the informed consent forms were 20 pages or longer. Page length and readability were weakly correlated.

Conclusion: Informed consent forms from high-risk trials at this single academic institution were lengthy and written at a readability level higher than the desired 7th-8th grade level. The length of the informed consent forms and their difficult readability may compromise subject understanding.

Submission Category: Practice Research/ Outcomes Research/ Pharmacoeconomics

Submission Type: Evaluative Study

Poster Title: Impact of pharmacotherapeutics course on APPE students' performance during an interprofessional medical mission trip

Primary Author: Breoscha West, Philadelphia College of Pharmacy, Pennsylvania; **Email:** bwest@mail.usciences.edu

Additional Author (s):
Kaitlin Emmerson
Shelley Otsuka
Yvonne Phan
Jessica Adams

Purpose: The rigorous curriculum that students must learn to receive a Doctor of Pharmacy degree must continuously be assessed and improved upon to ensure students are prepared to pursue interprofessional partnerships in conventional and unique settings. There is currently a gap in the literature evaluating the impact of a pharmacy curriculum on APPE students' performance during interprofessional medical mission trips.

Methods: This prospective study was reviewed and was determined to be exempt by the appropriate Institutional Review Board. The aim of this study was to correlate the impact of the didactic pharmacotherapeutics courses on APPE students' performance during an interprofessional medical mission trip. Data was collected during a 7-day medical mission trip in Jamaica for any patient who received medical care and prescribed medication from either the medical or dental team. De-identified patient data collected from medical charts included: patient characteristics, type of recommendation for each disease state, number of patient medications, member of pharmacy team that made the intervention (pharmacy preceptor, pharmacy student, or pharmacy student + preceptor). The quantitative data collected was then correlated back to the number of hours spent on each disease state in the pharmacotherapeutics course.

Results: Out of a total 1,881 prescriptions dispensed from the pharmacy on this mission trip, pharmacy students made interventions on 29.9% of the total prescriptions dispensed and made 69.2% of the total recommendations. The therapeutic topics that had the most number of

hours were pain (9 hours), hypertension (7 hours) and diabetes (6 hours). Most other topics such as sexually transmitted infections, fungal infections and skin/soft tissue infections had 2 hours each in the therapeutic curriculum. Students on the mission trip made recommendations on 66% of sexually transmitted infection medications, 40% of fungal infection medications, 37% of hypertension medications, 33% of diabetes medications and 18.9% of pain medications. The total number interventions made by the students was 661 and the most frequent type of student intervention was evidence-based recommendations. These recommendations included dosage strength formulation change (107), frequency (103), disease- specific recommendations (98) and duration of therapy (89).

Conclusion: After evaluating the data collected, there was an indirect association between the hours spent on various pharmacotherapeutic topics and recommendations pharmacy students made during the interprofessional medical mission trip. However, there were many limitations to this study including a restrictive medication formulary, which may have subsequently confounded the results. Gathering the same data from other interprofessional practice sites during APPE rotations may help guide pharmacotherapeutic curriculum changes.

Session-Board Number: 2-249

Poster Title: Performing an institution-wide gap analysis for pediatric medication safety using the Institute for Safe Medication Practices Survey on Pediatric Medication Safety Practices

Primary Author: Kayley Liuzzo, Philadelphia College of Pharmacy, Pennsylvania; **Email:** kliuzzo@mail.usciences.edu

Additional Author (s):
Michael Dejos

Purpose: According to the Institute for Safe Medication Practices (ISMP), pediatric patients are more likely than adults to experience harmful medication errors and adverse drug reactions due to their size, immature physiologic functions, inability to communicate adverse effects to caregivers, and calculation errors. ISMP developed an online Survey on Pediatric Medication Safety Practices in March 2015 asking physicians, pharmacists, and nurses to select the frequency with which they implemented key error-prevention strategies at their institutions. This project was designed to identify areas of medication safety improvement at Nemours Alfred I. duPont Hospital for Children using a gap analysis approach.

Methods: The results from this survey were verified by pharmacists, nurses, and informatics clinicians. Frequencies of implementation were documented with the options being always (>99% of the time), almost always (90-99% of the time), often (50-89% of the time), sometimes (20-49% of the time), rarely (1-19% of the time), or never (< 1% of the time). A likelihood of failure score, likelihood of detection score, and severity score were then assigned to strategies with the frequencies of often, sometimes, rarely, and never. The three scores were then multiplied to calculate a risk priority number (RPN) in order to prioritize the lowest ranking strategies. Based on the RPNs calculated, key areas of medication safety improvement were identified and recommendations were discussed with senior leadership.

Results: The keys areas of medication safety improvement identified included the use of barcode verification of ingredients in intravenous/oral liquid doses during preparation, the use of smart infusion pumps with an activated drug library to administer pediatric parenteral solutions, employing an independent double-check for high-alert parenteral drugs prior to administration, tracing the line from the medication/solution to the patient prior to

administration, having a clinical pharmacist present on patient care units to participate on rounds, and having prescribers order pediatric liquid medications in metric doses, not volume only. The results were shared with senior leadership and error-reduction strategies to fully implement these best practices were discussed.

Conclusion: The ISMP Survey on Pediatric Medication Safety Practices was useful in identifying medication safety gaps with prescribing, dispensing, and administration of medications at Nemours Alfred I. duPont Hospital for Children. The use of a gap analysis and RPNs allowed for the identification of gaps in best practices at this institution, along with prioritization of the gaps to implement error-reduction strategies.

Submission Type: Evaluative Study

Session-Board Number: 2-250

Poster Title: Systematic review: Evaluating cognitive and behavior factors affecting medication adherence

Primary Author: Aakash Gandhi, Philadelphia College of Pharmacy, Pennsylvania; **Email:** agandhi1640@mail.usciences.edu

Additional Author (s):
Rima Patel
Kayla Garzio
Grace Earl

Purpose: The World Health Organization (WHO) in 2003, declared that improving patient adherence will have better health implications than any other medical treatment can. According to the Center for Disease Control (CDC), medication adherence is when the patient properly conforms to the medication regimen recommended by the prescriber in respect to timing, dosage, and frequency. The aim of this systematic literature review is to examine causes of medication non-adherence, with an emphasis on behavioral and cognitive factors, and identify new trends in improving patient adherence and outcomes because it is crucial to educate clinical pharmacists about interventions to improve adherence.

Methods: A PubMed search was performed to identify new trends in medication adherence research using the criteria: Medication adherence (All Fields) AND methods (All Fields) AND chronic disease (all fields). The search was limited to abstracts in English. Abstracts were included if published between January 1, 2011 and January 15, 2015. 400 abstracts were identified. Articles were included if they examined medication adherence factors or used interventions in adult patients diagnosed with chronic diseases. If there was a disagreement regarding inclusion of any article, the authors met to discuss the article and arrive at a consensus. A flowchart was created to depict the number of articles that were included and excluded.
The articles were included if they evaluated medication adherence as an outcome that used a cognitive or behavioral intervention, or examined the association of these factors with adherence.

Articles were excluded if it evaluated non-cognitive/non-behavioral factors, was not a well-designed scientific study with results (review, protocol only, editorial, commentary, did not use pre-post measurement, control group, qualitative methods, validated scales), non-adults or non-chronic disease, not related to medication adherence, or a literature review.

Results: Out of 400 abstracts reviewed, 357 were excluded.

We included 43 articles which evaluated cognitive (20, 46.5%) and behavioral (4, 9.3%) factors influencing patients medication taking behaviors, or described interventions (16, 37.2%) based on these concepts. Additional articles described coordinated care interventions (3, 6.9%).

Emerging evidence on factors affecting patient adherence include:

Belief in God; self-efficacy and motivation (willing to take action and control of your disease); activation (confidence and knowledge to take action); perception toward treatment efficacy; perception of disease severity; motivation towards self-care; and quality of patient education/motivational interviewing.

Conclusion: Pharmacists must be aware of recent trends in order to engage patients in contemporary methods to promote adherence. Reasons for medication non-adherence include cognitive and behavioral factors such as perceptions/attitudes towards treatment, disease severity, and physician's expertise as well as motivation to improve their health outcomes. Pharmacists should integrate tools during patient encounters to identify if patients hold perceptions or beliefs that could be a barrier to taking their medications. Interventions using motivational interviewing and participation in workshops or disease management programs are also being investigated to educate patients and change their medication-taking behaviors.

Poster Title: Evaluation of non-administered basal insulin doses at a community medical center

Primary Author: Ariel Cohen, Philadelphia College of Pharmacy, Pennsylvania; **Email:** acohen@mail.usciences.edu

Additional Author (s):
Ariel Orland
Lauren Igneri
Christopher Shaw
Jessica Ellis

Purpose: The Institute for Safe Medication Practices identified that basal insulin doses are often inappropriately not administered to hospitalized patients. Basal insulins, which have durations of action up to 24 hours, should not routinely be held as this impairs glycemic control and has been shown to increase morbidity and mortality. In hospitalized patients, blood glucose (BG) should be maintained at 140-180 mg/dL. Institutional policy requires prescriber notification when doses are non-administered, regardless of the reason. This study aims to describe nursing practices surrounding basal insulin administration at a community medical center.

Methods: This retrospective chart review included hospitalized patients, aged 18 years and older, admitted between June-July 2016 with at least one documented administration or non-administration of insulin glargine or insulin detemir. Orders were excluded if the dose of basal insulin was discontinued prior to scheduled administration time. IRB approval was granted with a waiver of informed consent. Assessment of patients included demographics, prescriber information, number of scheduled insulin administrations, number of administered doses, and number of non-administered doses. Patients with at least one non-administered dose were further analyzed for BG prior to non-administration, time from last BG to non-administration, BG 2-8 hours after non-administration, and documentation of prescriber notification. The primary outcome was the proportion of subjects with at least one inappropriately non-administered basal insulin dose. Secondary outcomes included the proportion of non-administered doses for which there was no prescriber notification documented, and the documented reason why the dose was non-administered.

Results: 294 patients (1,682 potential doses of basal insulin) were included in the analysis with 58 patients (19.7 percent) having at least one non-administered dose of basal insulin (113 doses held; 6.7 percent in total). 50 of those 58 patients (86.2 percent) were found to have at least one inappropriately non-administered dose. Of those 50 patients with inappropriately non-administered doses, 46 (92 percent) did not have a prescriber notification documented. In the remaining 4 patients (8 percent) notification to the prescriber or the prescriber's answering service was documented. However, in these 4 cases, the doses were documented as non-administered prior to follow-up communication from the prescriber. Documented reasons for the 113 non-administered doses were as follows: low blood sugar (23.9 percent, n equals 27), patient refused dose (18.6 percent, n equals 21), nothing by mouth (14.2 percent, n equals 16), medication unavailable (0.9 percent, n equals 1), medication discontinued by prescriber (1.8 percent, n equals 2) and unspecified (40.7 percent, n equals 46)). The mean BG prior to hold was 127 mg/dL, with an average time from last BG to hold of 1.81 hours and a median of 1 hour. Mean BG 2-8 hours after hold was 141 mg/dL.

Conclusion: This study demonstrated a large proportion of patients with orders for basal insulin had inappropriately non-administered doses. Based on the findings, education initiatives surrounding appropriate administration and use of basal insulin in hospitalized patients will be introduced to nursing staff. Importance of communication and documentation will be stressed during education. A future study will evaluate post-education practices with basal insulin.

Poster Title: Impact of initiation of parenteral nutrition on glycemic control in elderly versus non-elderly patients

Primary Author: Shivani Bhanderi, Philadelphia College of Pharmacy, Pennsylvania; **Email:** sbhanderi@mail.usciences.edu

Additional Author (s):
Angela Bingham
Laura Pontiggia
Colleen Smith
James Hollands

Purpose: Hyperglycemia and insulin resistance have been described as metabolic features impacting elderly patients. However, the literature provides limited information about glycemic control in elderly patients receiving parenteral nutrition.
Advancing parenteral nutrition in patients with high blood glucose levels may lead to metabolic complications that can result in increased length of hospital stay along with increased morbidity and mortality. The purpose of this study is to determine the impact of parenteral nutrition on blood glucose concentrations in the elderly (age greater than or equal to 65) and non-elderly (age less than 65).

Methods: The institutional review board approved this retrospective study that included adult patients initiated on at least two days of parenteral nutrition during hospitalization from May 2014 to July 2016 at Cooper University Hospital. The primary outcome measure was a comparison of peak blood glucose concentrations and hyperglycemic episodes prior to initiation and on day 1 and day 2 of parenteral nutrition and total dextrose infusion rates for elderly versus non-elderly patients.. Categorical variables were analyzed using Chi-squared test and Fisher's exact test. Continuous variables were analyzed using Wilcoxon rank-sum test. The a priori significance level is 0.05.

Results: The peak blood glucose concentration was significantly higher in the elderly versus non-elderly patients on both day 1 (188.8 plus or minus 81.8 versus 164.3 plus or minus 60.8, P equals 0.0001) and day 2 (195.0 plus or minus 78.9 versus 171.2 plus or minus 67.8, P equals

0.0001) despite no difference in peak blood glucose concentrations prior to initiation (143.2 plus or minus 51.9 versus 129.7 plus or minus 49.8, P equals 0.0003). Similarly, there were more hyperglycemic episodes in the elderly on day 1 (0.79 plus or minus 1.62 versus 0.65 plus or minus 1.67, P equals 0.0402) and day 2 (1.13 plus or minus 1.85 versus 0.62 plus or minus 1.67, P less than 0.0001), while there was no difference prior to initiation (0.25 plus or minus 0.83 versus 0.16 plus or minus 0.7 , P equals 0.2174). Dextrose infusion rates (milligram/kilogram/minute) were not different between the elderly and non-elderly patients prior to initiation, on day 1, and day 2.

Conclusion: Initiation of parenteral nutrition led to more blood glucose abnormalities in elderly patients compared to non-elderly patients, as seen by higher peak blood glucose concentrations and more hyperglycemic episodes while receiving comparable dextrose infusion rates. Clinicians should be aware that elderly patients receiving parenteral nutrition are at a greater risk of this metabolic complication.

Poster Title: Impact of time to initiation of parenteral nutrition on outcomes in critically ill patients

Primary Author: Sunish Shah, Philadelphia College of Pharmacy, Pennsylvania; **Email:** sshah1741@mail.usciences.edu

Additional Author (s):
Angela Bingham
Laura Pontiggia
Richard Song
James Hollands

Purpose: The optimal time to initiate parenteral nutrition in critically ill adults in whom enteral nutrition is not feasible is controversial. The American Society for Parenteral and Enteral Nutrition guidelines recommend withholding parenteral nutrition over the first seven days if the critically ill patient is at low nutrition risk, but initiating as soon as possible if at a high nutrition risk and early enteral nutrition is not feasible. The purpose of this study is to investigate in-hospital mortality and hospital length of stay based on initiation of parenteral nutrition within seven days or after seven days of poor nutrient intake.

Methods: This single-center, retrospective study included critically ill adult patients who received at least two consecutive days of parenteral nutrition during hospitalization from January 1, 2013 to July 15, 2016. Patients were excluded if they were pregnant, received concomitant enteral nutrition or if they previously received parenteral nutrition. The primary objective was to compare in-hospital mortality in patients initiated on parenteral nutrition within seven days or after seven days of poor nutrient intake (less than 50 percent of daily nutritional requirement). The secondary objective was to compare hospital length of stay in patients initiated on parenteral nutrition within seven days or after seven days of poor nutrient intake. A subgroup analysis stratified patients based on nutrition classification at baseline: malnourished (actual body weight was less than 89 percent of ideal body weight), normal (actual body weight 90 to 129 percent of ideal body weight), or obese (actual body weight was greater than 130 percent of ideal body weight).

Results: 110 patients received parenteral nutrition within seven days of poor nutrient intake while 49 patients received parenteral nutrition after seven days of poor nutrient intake. In the subgroup analysis, 12 patients were malnourished, 78 patients were normal, and 69 patients were obese. There was no statistically significant difference in the in-hospital mortality based on initiation within seven days or after seven days (29.09 percent versus 18.37 percent, P equals 0.1535). In-hospital mortality was similar in both groups regardless of nutrition classification. Patients initiated within seven days had a shorter mean hospital length of stay than patients initiated after seven days (25.36 plus or minus 18.30 days versus 33.82 plus or minus 21.87 days, P equals 0.0013). Hospital length of stay was similar in both groups for patients who were considered malnourished or normal. Obese patients initiated within seven days had a shorter mean hospital length of stay than obese patients initiated after seven days (22 plus or minus 17.16 days versus 37 plus or minus 19.69 days, P equals 0.0007).

Conclusion: Time to initiation of parenteral nutrition did not have a significant impact on in-hospital mortality. However, patients who received parenteral nutrition within seven days of poor nutrient intake had a shorter hospital length of stay compared to those who received parenteral nutrition after seven days of poor nutrient intake. The small number of malnourished patients may have limited our ability to find a statistically significant difference in patient outcomes for this high nutrition risk patient population.

Poster Title: Pharmacy pain management interventions on a medical mission trip in rural Jamaica

Primary Author: Maura Jones, Philadelphia College of Pharmacy - University of the Sciences, Pennsylvania; **Email:** mjones100@mail.usciences.edu

Additional Author (s):
Taylor Jones
Erin Grannan
Thaddeus McGiness
Jessica Adams

Purpose: The 2016 Jamaica Medical Mission interdisciplinary team was comprised of medical, dental, nursing, and pharmacy students along with their respective preceptors. Students worked alongside preceptors to provide overall patient care. Pharmacy students recommended interventions in an effort to address and improve pain management. The purpose of this study was to evaluate and quantify types of pain management interventions made by pharmacy students on an international, interprofessional medical mission advanced pharmacy practice experience rotation.

Methods: A retrospective analysis of collected data from prescription records and dispensing logs during a 10-day medical mission trip was conducted from June 7th to June 17th, 2016. Data analysis specifically included prescriptions that were written for pain management. Background data collected included patient age, gender, medication, indication, type of recommendation and by whom the recommendation was made. The primary endpoint analyzed was the percentage of pharmacy interventions made on pain prescriptions from the medical and dental teams out of the total pain prescriptions dispensed. Interventions were defined as: medication changes (allergy, non-formulary, out of stock, unnecessary drug or therapeutic alternative), dose changes (strength, frequency, duration of therapy, dosage form or route of administration), and/or new medication recommendation (disease specific or new diagnosis). Secondary endpoints included the percent of interventions accepted by the team, categorization of the types of interventions made, percentage of pain medications filled for the

medical team compared to the dental team, and percentage of pain interventions made by the pharmacy student, student and preceptor together, or pharmacy preceptor alone.

Results: Of the 1881 total prescriptions, 639 were pain prescriptions; 423 from the medical team and 216 from the dental team. Pharmacy interventions were made on 35.2 percent of medical pain prescriptions and 10.6 percent of the dental pain prescriptions. Of the total pharmacy interventions provided, 94.2 percent were accepted by the healthcare team. Interventions by category on medical and dental prescriptions, in percentage respectively, were as follows: non-formulary (2.8, 0), therapeutic alternative (14.2, 0); dose changes due to strength (17, 27.3), frequency (20.5, 31.8), duration of therapy (17.6, 13.6), dosage form (10.2, 27.3); and new medication that was disease specific (11.4, 0), or new diagnosis (6.3, 0). Among the 149 interventions made on medical prescriptions, 73.6 percent were given by pharmacy students, 18.2 percent were given by pharmacy preceptors, and 8.1 percent were given with input from both a student and preceptor. Of the 23 interventions made on dental prescriptions, 52.2 percent were given by students, 39.1 percent were given by pharmacists and 8.7 percent were given with input from both a student and preceptor.

Conclusion: Pharmacy students on a medical mission trip provide diverse recommendations for pain management prescriptions as contribution to overall patient care. Their role in pain management therapy was clearly defined and reflected by the interventions conducted and accepted by the healthcare team as a whole. Pharmacists and students play a major role in monitoring the pain formulary and making recommendation based on adjustments to that formulary. This data can be used to support the impact pharmacy students can have on future medical mission trips to enhance the interprofessional pain management team.

Poster Title: Retrospective evaluation of direct oral anticoagulants and the impact of an in-patient pharmacist monitoring service

Primary Author: Hien Nguyen, Philadelphia College of Pharmacy-University of the Sciences, Pennsylvania; **Email:** hnguyen1694@mail.usciences.edu

Additional Author (s):
Jennifer Walls

Purpose: With the introduction of direct oral anticoagulants, routine therapeutic monitoring is not required. However, evaluation of dosage per indication, renal function, and associated drug-drug interactions are crucial. This project evaluated the impact of an in-patient pharmacist direct oral anticoagulant monitoring service when therapies of these agents are initiated in the hospital setting.

Methods: This is a retrospective chart review that evaluated hospitalized patients who received direct oral anticoagulation therapy during the month of May 2016 at Penn Medicine-Lancaster General Health. The institution's electronic medical record reporting system was used to generate a list of all patients who received anticoagulation. The only charts reviewed were of patients who received at least one dose of a direct oral anticoagulant, such as apixaban, dabigatran, edoxaban, or rivaroxaban, during their hospitalization. Patients were excluded from this study if they did not receive any doses of a direct oral anticoagulant or received anticoagulation other than direct oral anticoagulants. General patient demographics and laboratory values needed to evaluate therapy were recorded, as well as direct oral anticoagulant medication data from prescriber's orders. The primary outcome was to determine the number of pharmacist interventions facilitated through the monitoring service program of direct oral anticoagulants. Secondary outcomes included number of prescribed orders to each direct oral anticoagulant and interventions implemented to each agent. Additionally, pharmacist adherence to monitoring protocol, determination of the modes and types of pharmacist interventions, and acceptance of pharmacist interventions were reviewed. Furthermore, this study evaluated missed opportunities of potential pharmacist intervention for preventative harm. The Institutional Review Board has evaluated this research in an expedited process.

Results: During the month of May 2016, there were 233 pharmacist evaluations for direct oral anticoagulants. Two hundred twenty-four pharmacist evaluations were reviewed, due to 9 evaluations being duplicates of the same order or no direct oral anticoagulant was administered. Of those, 50 orders had pharmacist interventions. Apixaban was prescribed 134 times (59.8%) with 20 interventions (40%), dabigatran had 8 orders (3.6%) with one intervention (2%), rivaroxaban had 82 orders (36.6%) with 29 interventions (58%), and no edoxaban usage. Reasons for pharmacist interventions were due to drug-drug interactions (23 occurrences, 46%), renal dosing adjustments based on creatinine clearance and kidney function (18 occurrences, 36%), incorrect dosages (7 occurrences, 14%), and other clarifications (2 occurrences, 4%). Pharmacist interventions took place through automatic renal dose adjustment twice, 28 provider pages, and 28 sticky notes left for provider review. There were 8 occasions when both provider pages and sticky notes were used. Of the 50 pharmacist interventions, 22 were not accepted (44%), 13 partially accepted (26%), and 15 interventions fully accepted (30%). Incidences of missed opportunities for preventative harm in patients on the direct oral anticoagulants occurred at instances of new medication orders at discharge, unclear documentation, and loss to follow-up.

Conclusion: When evaluating direct oral anticoagulants, pharmacist interventions are fully accepted or at least partially accepted over half of the time. Further considerations include continued education to pharmacists on risk stratification for paging over placing a note for provider review, in order to establish a clearer mode of communication. Other opportunities to consider and optimize in the future, include yearly serum creatinine monitoring and discharge patient counseling to ensure patients have clear understanding in using their direct oral anticoagulant.

Poster Title: Safety and tolerability of rapid titration of intravenous treprostinil

Primary Author: Jennie Xu, Temple School of Pharmacy, Pennsylvania; **Email:** tuf26065@temple.edu

Purpose: Treprostinil is a prostacyclin analogue approved to treat pulmonary arterial hypertension (PAH) and is associated with improved symptoms from this progressive, chronic disease. The approved dosing of treprostinil is based on weekly titration to clinical effect; however, this may lead to delays in achieving symptom relief upon initiation. Rapid titration of intravenous treprostinil beyond the approved frequency has been utilized with little data to support this approach. The purpose of this study is to assess the safety and tolerability of rapid titration of intravenous treprostinil in our institution.

Methods: This was a single-center, retrospective, chart-review study. Institution review board approval of the study was obtained prior to data collection. Potential study subjects were identified using the pharmacy informatics database of patients receiving parenteral treprostinil between January 2006 and April 2016. Patients at least 18 years of age with a PAH diagnosis and newly initiated on intravenous treprostinil were included if dose titrations occurred more frequently than on a weekly basis. Minors, pregnant patients, and prisoners were excluded from the study. Baseline characteristics collected included age, gender, race, weight, past medical history, medications prior to admission, World Health Organization (WHO) group, New York Heart Association (NYHA) functional class, and pulmonary artery pressure (PAP). Dose titrations were evaluated based on initial dose, titration frequency, titration dose, maximum dose, and time to maximum dose. Effects on PAP, blood pressure, and adverse events during hospitalization were collected. Additionally, intensive care unit (ICU) and hospital length of stay (LOS) were collected. The primary outcomes were dose limiting side effects and any serious adverse events that might cause hemodynamic instability. Hemodynamic instability was defined in this study as hypotension that requires intervention with fluids or vasopressors. Secondary outcomes consisted of ICU and hospital length of stay. Data were analyzed using descriptive statistics to determine common titration practices and frequencies of any measured or observed adverse effects.

Results: A total of 10 subjects between the ages of 30-76 were included. The median PAP of study subjects was 83/33 mmHg and all subjects were in NYHA Class IV. The majority of the subjects were identified as WHO group III pulmonary hypertension. Nine patients had previously diagnosed PAH, six had COPD, asthma, or interstitial lung disease, four had hypertension, three had diabetes mellitus, three had osteoarthritis, and two had heart failure. Prior to initiation of treprostinil, seven subjects were on phosphodiesterase inhibitors, two on endothelium receptor antagonists, and three were on inhaled prostacyclin. Initial doses of treprostinil were 1-2.5 ng/kg/min. Eight subjects had their infusion titrated every 24 hours, with two subjects titrated between every 2-8 hours. Doses were titrated mostly by 1 ng/kg/min (70%) with the median maximum dose of 7.75 ng/kg/min. The mean time to maximum dose was 8.75 days and ICU and hospital LOS 9 days and 18.2 days, respectively. The most common adverse event was hypotension, which occurred in four subjects. Two of these subjects required intervention, with one requiring dose reduction and another requiring fluids and vasopressors. One subject experienced vomiting and another had jaw pain.

Conclusion: Rapid titration of treprostinil occurs with variable dosing strategies and appears to be a safe option in achieving stable doses for chronic management of PAH. Few adverse effects were observed in this study and are commonly known effects associated with use of treprostinil. There appears to be a small risk of causing hemodynamic instability, which may be managed with supportive care. Based on these data, a reasonable approach may be starting infusions at 1 ng/kg/min and titrating by 1 ng/kg/min every 24 hours to effect. Further study is required to confirm our findings.

Poster Title: Cebranopadol: novel dual opioid/NOP receptor agonist analgesic

Primary Author: Hallie Kinecki, Temple University School o Pharmacy, Pennsylvania; **Email:** halliekinecki@gmail.com

Additional Author (s):
Fangchen Lin
Victor Phan

Purpose: Chronic pain is a worldwide problem due to the limited efficacy, limiting adverse effect profile, or abuse potential of current analgesic options. Cebranopadol is an innovative novel agent that combines an agonist action at opioid receptors with agonist action at nociceptin/orphanin FQ peptide (NOP) receptors. It demonstrates good efficacy and safety in a variety of preclinical models of acute pain, and potent efficacy in preclinical models of neuropathic pain. If approved, cebranopadol would represent the first truly novel centrally-acting analgesic in many years. Because of this, we review the basic pharmacology and clinical trials of this novel analgesic.

Methods: Published literature and Internet sources were searched to identify information related to the basic science (pharmacology and medicinal chemistry) and development (clinical trial) information on the mechanism of dual opioid and NOP receptor pharmacologic action in general, and for cebranopadol in particular. Literature searches were conducted using sources such as PubMed and Ovid including keywords related to pain (such as physiology, types, chronification, etc.), analgesics (opioid and nonopioid), mechanisms of analgesic action, opioid receptors, NOP receptors, adverse effects, tramadol, tapentadol, buprenorphine, and cebranopadol, among others. Clinical trial information was obtained from the United States National Institutes of Health clinical trials directory. The identified sources were reviewed and the information synthesized.

Results: Efficacy: Cebranopadol displays antinociceptive and antihyperalgesic effects in rat models of acute and chronic pain including tail-flick, rheumatoid arthritis, bone cancer, spinal nerve ligation, and diabetic neuropathy.

Adverse effects: The potential for effects on respiration or motor activity/sedation were assessed using whole-body plethysmography and rotarod test in rats. At the maximum test dose tested which was 3.2-fold the analgesic ED50 dose in the tail-flick test, cebranopadol did not produce any significant changes in the measured respiratory parameters or on motor coordination. In comparison, morphine induced respiration depression and dose-dependent inhibition of motor coordination.

Cebranopadol produced similar rates of constipation as tapentadol ER, but only at a much higher dose.

NOP receptors are widely distributed throughout the brain and peripheral tissues and may affect other physiological functions. NOP receptor agonists have been reported to produce motor disturbance, memory impairment, and hypothermia. Further studies are needed to identify the side effect profile of mixed opioid/NOP receptor agents.

Abuse potential: Based on opioid/NOP receptor interaction studies, it seems plausible that cebranopadol could also have reduced abuse potential compared to these drugs. No publications were found that reported preclinical or clinical assessment of the abuse potential. Phase 3 trials are in process.

Conclusion: Cebranopadol displays analgesic, antihyperalgesic, and antiallodynic properties in several rat models of acute nociceptive, inflammatory, cancer, and neuropathic pain. Cebranopadol is significantly more potent than morphine in these tests, and is relatively more potent in chronic than acute pain models. Presumably due to the NOP receptor component of cebranopadol, development of analgesic tolerance is delayed compared to an equianalgesic dose of morphine. Additionally, unlike morphine, cebranopadol did not disrupt respiration or motor coordination at doses within and exceeding the analgesic dose range in rats, indicating it may be a safer alternative than traditional single-mechanism opioids.

Poster Title: Potential Rx-to-OTC Switch Drug Candidates

Primary Author: Victor Phan, Temple University School of Pharmacy, Pennsylvania; **Email:** victor.phan@temple.edu

Additional Author (s):
Albert Wertheimer

Purpose: The purpose of this study was to gain insight in what Rx legend drugs pharmacists think have a good enough safety profile to sell as OTC and, if any, what OTC drugs pharmacists think should be legend only.

Methods: This study was performed as a non-directional survey asking the 2 following questions: "What are some prescription only medications that you think would be okay to sell as nonprescription (over-the- counter and behind the counter)" and following that "If any, what are some OTC/BTC medications that you think should be prescription only?" Pharmacists who were surveyed were those in the Philadelphia area within convenient traveling distance or whose contact information was available or accessible. There were three modes of collecting data. The first method was traveling to pharmacies in person and giving the pharmacist a physical survey to complete. The second method was the creation of a survey monkey, identical to the physical survey, which was sent electronically via email, text, or Facebook. The third method was telephoning pharmacies and conducting the survey over the phone. Demographics of respondents' age range, education, area of work, and gender were collected. All methods were done as similarly as possible; with the same greeting and wording of questions, etc. Data analysis was done based on noticeable trends of answers and tallying frequencies of responses.

Results: 101 pharmacists were contacted. The most frequent suggestion for Rx-to-OTC switch was oral contraceptives. The three following were albuterol, Epi-Pen, and naloxone.
The most frequent suggestions of OTC medications that should be moved to Rx were Plan B and herbal supplements.

Conclusion: There are many prescription medications that practicing pharmacists believe are safe to sell as OTC. The most common medication is of oral contraceptives. This finding is

potentiated by the fact that California and Oregon have recently passed laws allowing pharmacists to prescribe both oral and hormonal contraceptives. If there is success with California and Nevada in the advancement of women's health by allowing pharmacists to prescribe contraceptives, we can expect that other states will follow suit. It is not unreasonable to expect that contraceptives have potential to be sold as non-prescription in the future.

Poster Title: IVIG-induced aseptic meningitis case report

Primary Author: Sophie Hien Le, Temple University School of Pharmacy, Pennsylvania; **Email:** tuf09058@temple.edu

Additional Author (s):
Loan Phan
Patrick McDonnell

Purpose: IVIG-induced aseptic meningitis: a case report
Case report: A 39 year old Hispanic female was admitted to the emergency department (ED) with a chief complaint of intractable headache. Two days earlier, the patient received two doses of intravenous immunoglobulin (IVIG) at 1g/kg (100 g) for her recent diagnosis of immune thrombocytopenic purpura (ITP). The patient reported having a severe headache within 15 minutes after the infusion of second dose of IVIG. She was treated with ibuprofen 600 mg and acetaminophen with codeine, but there was no sign of relief. Upon hospital admission, she reported having photophobia, nausea, pain rated as 10/10 but denied fever, diplopia, stiffed neck, or back pain. Her platelet count was recorded at 58K and vital signs showed her temperature was normal. A CAT scan confirmed that she had no intracranial hemorrhage. Order for a lumbar puncture was cancelled and ceftriaxone was ordered as a precaution. Blood and urine culture showed no acute infection. She was diagnosed with IVIG-induced aseptic meningitis during her
hospital stays.
In addition to her ITP, her PMH also included a history of catamenial migraine headaches, cervical cancer with hysterectomy, chronic hepatitis C, and obesity. She has no known drug allergies, denies the use of home medications or non-prescription therapies/dietary supplements, tobacco, alcohol or recreational drug use. She was not being treated for hepatitis C, as many of the treatments are contraindicated with her ITP/thrombocytopenia in general. IVIG is a standard treatment for primary and secondary ITP. In relation to ITP, IVIG is theorized to inhibit platelet phagocytosis by the macrophages. Macrophages have FcγR receptors on their surfaces that mediate inflammatory pathway, and IVIG contains Fc components that would inhibit the FcγR receptors.

Overall, drug induced aseptic meningitis (DIAM) is a rare adverse drug reaction associated with numerous agents. IVIG is one of the more common agents associated with this uncommon adverse effect. Mechanisms for DIAM include hypersensitivity reactions, stabilizing products in drugs, cytokine release, cerebrovascular sensitivity, and direct meningeal irritation. This patient being obese was given a high dose of IVIG based on her actual weight. This combined with her history of migraines; more than likely made her more susceptible to IVIG induced aseptic meningitis. Slow infusions of low-concentration IVIG products along with hydration may help reduce the risk of DIAM, especially in higher risk patients. For obese patients, IVIG packet inserts have no mention of any dose adjustments using an ideal or adjusted body weight, and perhaps this may need to be studied or explored.

Poster Title: Clenbuterol-induced Rhabdomyolysis: A Case Report

Primary Author: Arun Mohanan, Temple University School of Pharmacy, Pennsylvania; **Email:** tua82118@temple.edu

Additional Author (s):
Eric Nguyen
Patrick McDonnell

Purpose: The patient is a 32 year old male who presented to the emergency department in mild distress complaining of diffuse myalgias, tachycardia, weakness, arm pain, and muscle twitching for the past 4-5 days. During the past week, he had started a vigorous exercise program. Two days prior to his admission, he started taking clenbuterol tablets based on a recommendation from his trainer to assist in reducing fat and increasing muscle mass. On admission, his laboratory results showed hypokalemia with a serum potassium of 3.3 meq/L and an elevated creatine kinase of 3873 IU/L. . His condition was noted as "acute toxin-related myopathy consistent with clenbuterol injury, hypokalemia- induced muscle injury, and rhabdomyolysis without current evidence of pigment nephropathy:" The patient's condition improved with fluid hydration and was discharged a few days later.

Clenbuterol is a "dietary supplement" used by athletes and bodybuilders for its supposed performance enhancing and fat burning properties. It is not FDA approved for human use, although outside the U.S. it is approved for bronchial asthma. It is a long-acting ß-adrenoceptor agonist that exerts a potent broncholytic effect by preferential action on ß2-adrenoceptors in smooth muscle, resulting in the relaxation of bronchial smooth muscle and a decrease in airway resistance.

The mechanism of action of the clenbuterol induced rhabdomyolysis seen in this case is not fully elucidated although it is suspected it may be related to beta-2 agonist properties. In high doses clenbuterol can increase protein deposition and lipolysis similarly to anabolic steroids. The myotoxic effects could be due to the depletion of muscle energy stores possibly related to potassium depletion. Normally, during exercise, muscles release intracellular potassium causing local pockets of hyperkalemia which triggers vasodilation and increases perfusion to the active myocytes. Total body potassium depletion and hypokalemia decrease local hyperkalemia preventing the vasodilation, which results in tissue hypoxia and rhabdomyolysis.

Consumers often regard workout supplements as not 'true medications' and overlook their safety issues. Since the use of clenbuterol for fat-loss or for exercise endurance is not FDA approved, clenbuterol supplements are not required to have proper labeling and warnings. Additionally, dosing recommendations and regimens do not come from medical professionals or clinical trials, but from anecdotal evidence from users and there can be much variability; which is another factor that can contribute to its toxicities.

Poster Title: Neuroleptic malignant syndrome

Primary Author: An Shao, Temple University School of Pharmacy, Pennsylvania; **Email:** tue48043@temple.edu

Additional Author (s):
Ejike Chukwukere
Wykeem Parker

Purpose: A 55-year-old female with an altered mental status presenting as severe distress with decreased level of consciousness, hyperthermia, and agitation was brought to the emergency. The patient had a PMH of schizophrenia and dementia and was on a combination of typical and atypical antipsychotic medications that included haloperidol and quetiapine. Upon examination, the patient was tachycardic and with increased respiratory rate, along with an elevated creatine kinase, and bradyreflexia with reports of muscle rigidity. In addition to these findings she was also on dual SSRI therapy with fluoxetine and paroxetine, so concerns of serotonin syndrome was also considered. Initial therapy was primarily supportive with benzodiazepines for clonus activity, cooling blankets for hyperthermia, and fluid resuscitation. All her antipsychotic and antidepressant medications were not restarted upon presentation. After her initial treatment in the emergency room, neurology and psychiatry consults felt her presentation was more consistent with neuroleptic malignant syndrome, and therapy with dantrolene, and dopamine agonists, namely bromocriptine and ammantidine were initiated. Based on her good response to the skeletal muscle relaxant, dantrolene and dopamine agonists, a final diagnosis of neuroleptic syndrome was made. Unfortunately during her initial unresponsive state, she aspirated and developed pneumonia with sepsis and expired due to a secondary sepsis syndrome due to aspiration pneumonia.

Neuroleptic malignant syndrome (NMS) is an idiosyncratic, adverse drug reaction. It can be described as a cascade of dysregulation involving different organs of the body, ultimately leading to end-stage hypermetabolic syndrome. The exact mechanism of action of NMS cause by antipsychotic drugs is unknown. Their mechanism of action involves decreasing dopamine levels in the hypothalamus, nigrostriatal pathways, and spinal cord, which lead to increased muscle rigidity and tremor via D2 receptor antagonism. Peripherally, antipsychotics lead to increased calcium release from the sarcoplasmic reticulum in the muscle, resulting in increased

contractility, which results in muscle cell breakdown. In addition, reductions in the dopaminergic tone in the hypothalamus also contribute to the elevated temperature and impairment of heat-regulating systems, which induce further dysregulation of the autonomic response.

Despite the difficulties in a definitive diagnosis of NMS, health care providers should be familiar with presenting findings of this syndrome and provide initial supportive care to prevent further harm.

Poster Title: Intracranial hemorrhage with the use of apixaban

Primary Author: Melanie Zaniewski, Temple University School of Pharmacy, Pennsylvania;
Email: tuf33637@temple.edu

Additional Author (s):
David Froelich
Patrick McDonnell

Purpose: Intracranial hemorrhage and apixaban use
The patient is a 76-year old male who presents to the emergency department with symptoms indicative for stroke. Prior to his arrival at the emergency department, his wife had found him with altered mental status and the inability to stand that later resulted with him becoming unresponsive. His past medical history was significant for cerebrovascular accident and atrial fibrillation and was taking apixaban (no dose reported) for secondary stroke prevention. He arrived at the emergency department with a blood pressure of 229/142, acute headache, left-side weakness, and slurred speech. A computerized tomography scan of the patient's head revealed a massive right-sided basal ganglia hemorrhage with extension into the temporal lobe. The patient was diagnosed with a right intraparenchymal hemorrhage and required a craniotomy with evacuation of the hemorrhage. The patient's condition continued to decline, and on hospital day eight, he was discharged to hospice.
Bleeding is a significant adverse event associated with the use of anticoagulant medications. Although intracranial hemorrhage is relatively rare, when it does occur, it is associated with poor survival outcomes. The introduction of the novel anticoagulants has raised some questions about the safety of these medications, especially in the elderly. These medications are renally eliminated, and the liable nature of kidney function in elderly populations may pose problems such as drug accumulation. Unlike warfarin, these medications do not require blood testing for monitoring per their labeling nor do they have established defined coagulation test ranges for either efficacy or toxicity. Secondly, there are no known FDA approved reversal agents for apixaban or its competitor rivaroxaban, both oral Factor Xa inhibitors. Clinicians must rely on supportive therapy, blood products, and clotting factor products.
With the increase in popularity of the novel anticoagulants, the need for agents that can reverse the actions of these medications is apparent. Last year, the FDA approved

idarucizumab, a reversal agent for direct thrombin inhibitor, dabigatran. There are currently several agents in phase I clinical trials that have shown promise as possible reversal agents for both apixaban and rivaroxaban. In addition, prudent patient selection, particularly in the elderly, is greatly needed when using these newer agents without defined objective parameters for monitoring anticoagulant therapy.

Poster Title: Diabetes insipidus induced by lithium toxicity: a case report

Primary Author: Cory Ryhal, Temple University School of Pharmacy, Pennsylvania; **Email:** ryhalcj@temple.edu

Additional Author (s):
Luke Russo
Patrick McDonnell

Purpose: Diabetes insipidus induced by lithium toxicity: a case report
Case Report: A 50 year old Caucasian female presented to the emergency department with a chief complaint of worsening movement disorders possibly due to tardive dyskinesia over the previous two weeks affecting her quality of life. Vomiting and diarrhea along with decreased oral intake were also noted over the previous two weeks.
The patient had been on lithium therapy for about 8 years for the treatment of bipolar disorder and it was continued on admission. On hospital day 3, a lithium level was found to be toxic at 2.3 mEq/L and her sodium levels began rising towards dangerous levels (several levels > 150 mEq/L). Increased free water loss was noted but dismissed as being secondary to fever and tachycardia. Her urine osmolality was found to be low at (207 mOsm/kg) while the serum osmolality was elevated (349 mOsm/kg). The etiology of the patient's hypernatremia was thought to be secondary to free water deficits and possible nephrogenic diabetes insipidus from lithium toxicity. The patient received D5W (250 ml/hr) to correct for free water deficit. Desmopressin was considered to treat lithium-induced diabetes insipidus, however this recommendation was not taken. Tachycardic findings prompted a review of thyroid function tests, and she was found to be hyperthyroid and started on methimazole therapy. Lithium therapy was held, and fluid and electrolyte imbalances were corrected. The delay in diagnosis of this "drug induced disease" resulted in a prolonged hospital stay for this patient.
Lithium has a narrow therapeutic index and signs and symptoms of lithium toxicity need to recognized, particularly fluid loss and electrolyte imbalances. Also a spectrum of lithium toxic effects (hypernatremia, diabetes insipidus and hyperthyroidism) were not recognized or immediately connected as drug toxicity. Although commonly known to cause hypothyroidism, lithium has also been linked with hyperthyroidism. Identification of lithium toxicity as the underlying cause would have greatly reduced the patient's hospital stay. The objective findings

of a low urine osmolality coinciding with elevated serum osmolality strongly suggests diabetes insipidus. While focus remained on treating tardive dyskinesia, attention should have been paid to toxic lithium levels. The exacerbation of hyperthyroidism when combined with increased free water loss and elevated sodium levels implicates lithium toxicity.

Lithium is a complicated drug with a relatively unknown mechanism of action. Due to the narrow therapeutic index, lithium therapy requires serial drug level monitoring. Lithium's similarities with sodium ions can often lead to complex adverse reactions relating to renal function and electrolyte levels. Toxicity can lead to confusion, lethargy, and slurred speech. Severe toxicity can result in permanent neurological impairment, seizures, cardiovascular collapse, coma, stupor, and even death. Lithium induced diabetes insipidus results from accumulation of the drug within renal collecting duct cells, interfering with the actions of ADH and leading to polyuria and very dilute urine. In this patient case, this water loss along with lack of intake due to dyskinesia symptoms lead to severe hypernatremic dehydration, with sodium levels as high as 166 mEq/L. Early recognition of fluid and electrolyte imbalance both predispose a patient to lithium toxicity, as well as resulting from lithium toxicity.

Poster Title: Narrow Therapeutic Index Drugs: How the FDA and the Worlds Regulatory Agencies Raised the Bar for Bioequivalence

Primary Author: Jonathan Douek, Temple University School of Pharmacy, Pennsylvania; **Email:** tuf22799@temple.edu

Additional Author (s):
Trang Tran

Purpose: Define Bioequivalence (BE) and Narrow Therapeutic Index (NTI)
Characterize the qualifications of BE standards for NTI drugs in different regulatory agencies
Discuss the new FDA BE standards for NTI drugs and how they are different from those of other regulatory agencies around the world
Discuss how the new FDA reference-scaled BE approach will affect the landscape of generic drug approvals for NTI drugs

Methods: Our review was done through comparing guidances and guidelines from the FDA, EMA, and Health Canada, on criteria for conducting bioequivalence studies, as well as by reviewing relevant studies on this topic. Studies include articles on the deficiencies of the FDA in evaluating generic formulations of NTI drugs, and "Novel BE approach for NTI Drugs", an evaluation of this reference-scaled approach, and case studies on generic substitution of NTI drugs.

Results: -How the previous BE standards did not work for NTI drugs
-FDA's reference-scaled, 4-way, fully replicated crossover design is the preferred method of conducting BE studies for NTI drugs, as it is more flexible in accounting for "within subject variability" (WSV).
-The EMA and Health Canada have instituted a "cookie-cutter" approach, setting BE standards as AUC and Cmax of 90-111.11% for any new applications of generic NTI drugs.

Conclusion: Even though many regulatory agencies around the world have tightened up their BE standards for NTI drugs, FDA's approach also takes into account the WSV for their BE

requirements. This approach helps limit the approvals of NTI generic drugs that may have significant therapeutic differences from the Reference Listed Drug (RLD).

FDA may consider doing post-marketing reviews on NTI generic drugs that are approved with new reference-scaled BE approach to see if there are any therapeutic differences between generic and RLD.

Poster Title: IVIG induced aseptic meningitis: A case report

Primary Author: Loan Phan, Temple University School of Pharmacy, Pennsylvania; **Email:** tue47621@temple.edu

Additional Author (s):
Sophie Hien Le
Patrick McDonnell

Purpose: Case report: A 39 year old Hispanic female was admitted to the emergency department (ED) with a chief complaint of intractable headache. Two days earlier, the patient received two doses of intravenous immunoglobulin (IVIG) at 1g/kg (100 g) for her recent diagnosis of immune thrombocytopenic purpura (ITP). The patient reported having a severe headache within 15 minutes after the infusion of second dose of IVIG. She was treated with ibuprofen 600 mg and acetaminophen with codeine, but there was no sign of relief. Upon hosptial admission, she reported having photophobia, nausea, pain rated as 10/10 but denied fever, diplopia, stiffed neck, or back pain. Her platelet count was recorded at 58K and vital signs showed her temperature was normal. A CAT scan confirmed that she had no intracranial hemorrhage. Order for a lumbar puncture was cancelled and ceftriaxone was ordered as a precaution. Blood and urine culture showed no acute infection. She was diagnosed with IVIG-induced aseptic meningitis during her hospital stays.

In addition to her ITP, her PMH also included a history of catamenial migraine headaches, cervical cancer with hysterectomy, chronic hepatitis C, and obesity. She has no known drug allergies, denies the use of home medications or non-prescription therapies/dietary supplements, tobacco, alcohol or recreational drug use. She was not being treated for hepatitis C, as many of the treatments are contraindicated with her ITP/thrombocytopenia in general. IVIG is a standard treatment for primary and secondary ITP. In relation to ITP, IVIG is theorized to inhibit platelet phagocytosis by the macrophages. Macrophages have FcyR receptors on their surfaces that mediate inflammatory pathway, and IVIG contains Fc components that would inhibit the FcyR receptors.

Overall, drug induced aseptic meningitis (DIAM) is a rare adverse drug reaction associated with numerous agents. IVIG is one of the more common agents associated with this uncommon adverse effect. Mechanisms for DIAM include hypersensitivity reactions, stabilizing products in

drugs, cytokine release, cerebrovascular sensitivity, and direct meningeal irritation. This patient being obese was given a high dose of IVIG based on her actual weight. This combined with her history of migraines; more than likely made her more susceptible to IVIG induced aseptic meningitis. Slow infusions of low-concentration IVIG products along with hydration may help reduce the risk of DIAM, especially in higher risk patients. For obese patients, IVIG packet inserts have no mention of any dose adjustments using an ideal or adjusted body weight, and perhaps this may need to be studied or explored.

Poster Title: Neutropenia and leukopenia secondary to immunosuppression after orthotopic heart transplantation: a case report

Primary Author: Julia Lees, Temple University School of Pharmacy, Pennsylvania; **Email:** tuc43302@temple.edu

Additional Author (s):
Jola Salavaci
Michael Barros
Patrick McDonnell

Purpose: The patient is a 62 year old African American male on an immunosuppressive regimen including tacrolimus, mycophenolate mofetil, prednisone, along with sulfamethoxazole/ trimethoprim, nystatin, and valganciclovir status post orthotopic heart transplant. Valganciclovir is a necessary medication because the patient was a cytomegalovirus mismatch. Shortly thereafter, the patient is admitted to the hospital with an absolute neutrophil count of 680/microliter, white blood cell count of 1000/microliter, hemoglobin as well as hematocrit counts of 13 grams/deciliter and 40.8% and platelet count of 102,000/microliter. He received colony stimulating factors to increase the production of neutrophils and was discharged from the hospital when the absolute neutrophil count rose to 2000/microliter, and white blood cell count increased to 2700/microliter. The patient was diagnosed with neutropenia and leukopenia secondary to mycophenolate mofetil use, which was subsequently discontinued. However, a hematology consult reported that a different agent was responsible. Mycophenolate mofetil is a reversible blocker of inosine monophosphate dehydrogenase, therefore affecting lymphocyte production, which diminishes cytotoxic T cell responses and antibody formation against the allograft. It is important to note that the mycophenolate mofetil dosage was reduced to half prior to the hospitalization due to decreased neutrophils at an outpatient visit. Any mycophenolate mofetil dose reduction increases the risk of acute rejection and graft loss.

Within a month, the patient is hospitalized again with an absolute neutrophil count of 430/microliter, white blood cell count of 1500/microliter, and a platelet count of 148,000/microliter. After this second hospitalization, valganciclovir was discontinued, which was the agent that hematology attributed to the initial neutropenia and leukopenia.

Cytomegalovirus protocol states that patients need to be on therapy for 3-6 months to decrease the risk of infection, but valganciclovir is known to have enhanced synergistic immunosuppression in combination with mycophenolate mofetil. Severe leukopenia, neutropenia, thrombocytopenia, bone marrow aplasia, and aplastic anemia have been reported in patients treated with this combination. Pancytopenia is included in the labeling and concomitant use of these agents can lead to a worsening hematologic effect for the patient. This case explores the clinical scenario when a patient is neutropenic and/or leukopenic but requires cytomegalovirus prophylaxis after receiving solid organ transplantation.

Poster Title: Evaluation of tacrolimus monitoring in solid organ transplantation at a single center teaching institution

Primary Author: Sneh Patel, Temple University School of Pharmacy, Pennsylvania; **Email:** tub55051@temple.edu

Additional Author (s):
Brianne Dunigan-Tenety
Michee Etienne
Jenny Lam
Julia Lees

Purpose: The purpose of this drug use evaluation (DUE) was to assess the appropriateness of tacrolimus therapeutic drug monitoring at Temple University Hospital (TUH) with respect to patient-specific serum concentrations, appropriateness of dose changes, and conversions between oral and sublingual formulations.

Methods: This evaluation was a retrospective, observational DUE of tacrolimus monitoring at TUH. Patients with orders for tacrolimus between July 1 and September 30, 2015 for immunosuppression post-transplant were included in the evaluation. Patients were excluded if they were less than 10 days post-transplant, received tacrolimus therapy for anything other than organ transplant, or were hospitalized less than 3 days due to readmission. Due to the half-life of tacrolimus, dose adjustments were considered appropriate if changes were made 48 to 72 hours after the previous dose change to allow tacrolimus to reach steady-state concentrations. Pertinent information obtained included the goal range, if documented, time post-transplant (less than 6 months or greater than 6 months), tacrolimus serum concentrations, dosages and formulations that were administered.

Results: Fifty-six out of 93 patients were included in this evaluation. One-hundred eighty-nine out of 432 (44 percent) tacrolimus concentrations obtained were in goal range while 18 percent of concentrations were supratherapeutic and 38 percent were subtherapeutic. There were 151 dose adjustments made where 69 (46 percent) adjustments were determined to be appropriate and 82 (54 percent) adjustments were deemed to be inappropriate. For secondary outcomes,

there were 177 out of 432 (41 percent) tacrolimus concentrations obtained that were determined as excessive. Twelve out of 16 patients (75 percent) were converted incorrectly between sublingual (SL) and oral (PO) dosage forms.

Conclusion: We found that dose adjustments and therapeutic monitoring were not conducted at optimal intervals. Inappropriate dosage changes resulted from frequent dose adjustments and failure to adjust dose due to sub- or supratherapeutic serum level. Tacrolimus serum concentrations were largely spent outside of goal range. We also found that the conversion between the SL and PO formulations were consistently incorrect.

Poster Title: Nivolumab and Clostridium difficile colitis: a case report

Primary Author: Mary McIntyre, Temple University School of Pharmacy, Pennsylvania; **Email:** tuc06097@temple.edu

Additional Author (s):
Avie Eckles

Purpose: The patient is a 68-year-old male with a past medical history including stage IV renal cell carcinoma, adrenal insufficiency and stage IV chronic kidney disease. The patient began nivolumab 2 mg/kg IV every 3 weeks off label for his renal carcinoma. Three months later, the patient began complaining of loose stools, but nivolumab was continued. Nivolumab was not discontinued until five months later, when his GI symptoms had progressed to 3-4 loose stools per day. The patient began treatment for sinusitis with amoxicillin and levofloxacin three days after his last dose of nivolumab. He was also taking pantoprazole 40 mg daily, chronically. The patient was admitted to the hospital approximately two weeks after the last dose of nivolumab and completed courses of antibiotics. Upon admission, he was diagnosed with Clostridium difficile colitis and was treated with oral vancomycin. Three days later, the patient was transferred to the ICU with sepsis and 20 bowel movements per day. He was given oral vancomycin, IV metronidazole and steroids. A colonoscopy revealed pseudomembranes and friable mucosa. Two weeks later, the patient was evaluated for fecal microbiota transplant (FMT). He was scheduled for FMT, but never received the procedure. Hours prior to it, the patient complained of chest pain, and an electrocardiogram revealed a non-ST elevation myocardial infarction. The following day, the patient elected for comfort care. He was then discharged to inpatient hospice.

Nivolumab can cause colitis due to its mechanism as an immune checkpoint inhibitor through PD-1:PD-L1 pathway blockade. This pathway plays a role in GI mucosal regulation which is disrupted by this medication. The patient presented with these symptoms of early colitis 12 weeks into treatment with nivolumab, at which time the medication should have been held. However, the patient continued treatment for another 20 weeks.

During this time, he was given antibiotics, which were not renally adjusted for his estimated creatinine clearance of 30 ml/min. This patient took these high-risk antibiotics while also on a proton pump inhibitor. The combination created the ideal environment for C. difficile to thrive.

The patient's PMH of adrenal insufficiency may have also been a precipitating factor, as this is a reported adverse effect of nivolumab as well as a known risk factor for diarrhea. Additionally, FMT has a much higher cure rate after recurrence of C. difficile, and this patient may have benefited by receiving the procedure earlier.

Conclusion:

Poster Title: Evaluation of naloxone use in hospital associated opioid overdose

Primary Author: Jennifer Ho, Temple University School of Pharmacy, Pennsylvania; **Email:** jenniferho@temple.edu

Additional Author (s):
Ashley DePuy
Olivia Stanton-Ameisen
Sara Walton
Jennifer Andres

Purpose: The purpose of this drug use evaluation was to analyze Temple University Hospital's (TUH) action prior to and following the inpatient administration of the opioid reversal agent, naloxone. The mu opioid antagonist counteracts symptoms of opioid overdose such as respiratory depression, sedation, and hypotension.

Methods: This is a retrospective chart review which analyzed patients admitted to TUH who received at least one dose of intravenous naloxone between July 2014-September 2015. The primary outcome was to determine if TUH's response following naloxone use was appropriate, defined as a decrease in the dose or frequency of the opioid regimen (in oral morphine equivalents) within 24 hours following naloxone administration. Secondary outcomes included evaluation of patient characteristics such as renal or hepatic function, opioid naivety, and age, as well as opioid regimen within 24 hours prior to naloxone, reversal rate of opioid overdoses, and documentation of clinical improvement.

Results: Five hundred and twelve patients were screened and 38 were included in the analysis. TUH had an appropriate response following naloxone administration in 86 percent (31/36) of the cases. On average, TUH gave higher risk patients, such as elderly with renal dysfunction and opioid naive patients, lower opioid doses than younger patients and those with normal organ function. Overall, the most common opioid implicated in overdose was morphine (31 percent) and 63 percent (24/38) of patients had renal dysfunction. 95 percent (36/38) of opioid overdoses were reversed with naloxone, and 92 percent (35/38) of the cases had documentation of clinical improvement. As for documentation, there was inconsistency in

regards to the time of naloxone administration, number of doses, and the patient's clinical response.

Conclusion: TUH's response to opioid overdoses was appropriate, however we would recommend that a standardized method for documenting naloxone use and response be implemented.

Poster Title: Etanercept-induced cardiomyopathy: a case report

Primary Author: Stephen Morgado, Temple University School of Pharmacy, Pennsylvania;
Email: stephen.morgado@temple.edu

Additional Author (s):
Ashley Karpovich
Patrick Mcdonnell

Purpose: Case Report: A 36 year old male recently presented to the emergency room with a 3-4 day history of chest pain with no radiation, shortness of breath and generalized weakness. He denied cough, expectoration or orthopnea. Pertinent lab results include an elevated WBC count of 12.8x 109 cells/L. Other pertinent findings included acute respiratory distress, tachycardia and tachypnea. He was then admitted to the telemetry unit with suspected community acquired pneumonia. Upon cardiology consult to investigate the cause of chest pain, he was found to have an EF of 25% and BNP of 182 pg/mL, both indicative of systolic dysfunction. The patient has a past medical history of psoriasis for which he was treated with etanercept on and off for the past 20 months. His discharge diagnosis included community acquired bilateral pneumonia and non-ischemic cardiomyopathy. Etanercept therapy for his psoriasis was not resumed on discharge.
Although it is a very uncommon adverse reaction, it has been shown in post-marketing reports that etanercept can cause worsening or new-onset heart failure. The patient did not have any significant risk factors for heart failure outside of etanercept use. It is rarer to see a drug induced-heart failure occur in young patients without comorbid conditions.
It was found that TNF-α levels are elevated in patients with severe heart failure, but the pathogenicity of etanercept causing cardiomyopathy is undetermined at this time. Although the mechanism is unclear, there are promising theories to explain this reaction. One theory involves TNF-α damaging cardiomyocytes due to increased free TNF-α levels in peripheral circulation. Free levels of TNF-α have been shown to display negative inotropic effects, and activate metalloproteinases responsible for increasing extracellular matrix remodeling. Another mechanism involves the selectivity that etanercept displays in inactivation of soluble TNF-α. This causes unopposed transmembrane TNF-α signaling, leading to anti-apoptotic and pro-inflammatory actions including increased TNF synthesis.

Poster Title: Nivolumab-induced diabetic ketoacidosis: a case report

Primary Author: Lauren Kobren, Temple University School of Pharmacy, Pennsylvania; **Email:** tuf23468@temple.edu

Additional Author (s):
Alexandria Charno
Melissa Ranieri
Patrick McDonnell

Purpose: Case Report: This case report highlights a novel adverse drug reaction that occurred after administration of nivolumab, an anti-PD-1 (anti-programmed cell death) monoclonal antibody, which is used as second- or third-line targeted therapy in a variety of cancer treatment regimens.

A 34-year-old African American female with a history of metastatic non-small cell lung cancer presented to the hospital with a chief complaint of nausea, vomiting, and abdominal cramping. On admission, she presented with a blood glucose of 739 mg/dL, BUN 38 mg/dL, SrCr 1.97 mg/dL, pH of 7.24 and an anion gap of 30 mEq/L, which was consistent with a diagnosis of diabetic ketoacidosis. She had been initiated on nivolumab one month prior for metastatic non-small cell lung cancer and had received two doses. The patient was diagnosed with diabetic ketoacidosis with acute kidney injury despite having no personal history of diabetes mellitus, which suggested that it was secondary to the recent initiation of nivolumab.The patient was treated in intensive care, where she received an insulin infusion and IV fluids. Her hospital stay was marked by uncontrolled blood glucose. She was ultimately discharged after an eleven-day hospital stay on all of her home medications (excluding nivolumab), and the following medications were added: insulin glargine 10 units subcutaneously at bedtime and insulin aspart 5 units subcutaneously three times daily before meals.

This patient incurred two subsequent hospital admissions, each within 24 hours of discharge, for diabetic ketoacidosis. Each time, she was treated in the intensive care unit with IV fluids and an insulin infusion, and her blood glucose was difficult to control. This resulted in eleven additional days of hospitalization and a delay in alternative antineoplastic treatment for her non-small cell lung cancer. Ultimately, the patient was initiated on an insulin pump for optimal control of her blood glucose levels.

This was a severe adverse drug reaction, as the patient developed diabetes mellitus secondary to nivolumab, a permanent complication. As this case demonstrates, the patient and the healthcare team must assess the risks versus benefits when initiating nivolumab, an anti-PD-1-monoclonal antibody, for the treatment of non-small cell lung cancer. The risk of diabetes mellitus, although rare, has been documented with this class of drugs. This potential adverse effect must be balanced with the treatment benefits of nivolumab for patients with advanced non-small cell lung cancer.

Poster Title: Clinical impact of a novel interprofessional dental and pharmacy student tobacco cessation education program on dental patients

Primary Author: Jillian Lykon, Temple University School of Pharmacy, Pennsylvania; **Email:** tuc37009@temple.edu

Additional Author (s):
Matthew Boyd
Jacqueline Theodorou
Shannon Myers Virtue
Melissa Rotz

Purpose: The dental setting is an ideal place to address tobacco use; however, many dentists feel unprepared in some aspects of tobacco cessation education, particularly recommending pharmacologic treatments. Pharmacists promote safe and effective pharmacologic treatment options for tobacco dependence. A interprofessional education (IPE) effort between dentistry and pharmacy may address this need for more extensive tobacco cessation education in the dental setting. This purpose of this study was to compare IPE versus standard care (SC) groups regarding dental patients' knowledge gained about tobacco cessation, intentions to quit tobacco use, quit attempts at follow-up, and perceptions of IPE care.

Methods: This was a pilot prospective study. Patients included in the study were seen at Temple University's Kornberg School of Dentistry admissions clinic, current tobacco users, eighteen years of age or older, able to speak, read, and write in English, able and willing to give informed consent, and able to provide a telephone contact number in order to complete the follow-up assessment. Both groups completed an initial survey during their dental appointment as well as a four-week follow-up phone survey. The initial survey questions included demographic data, tobacco use, previous quit attempts, perception of knowledge gained regarding tobacco cessation, intentions to set a quit date and to use pharmacologic tobacco cessation agents, and perceptions regarding IPE care. Questions assessing patient satisfaction were added to the IPE care survey. The four-week follow-up survey questions included perceptions of knowledge regarding tobacco cessation, quit intentions and quit attempts made since the dental appointment. A 5-point Likert-type scale was used to assess perceptions of

knowledge gained, quit intentions, and perceptions of IPE care. Non-parametric tests (Mann-Whitney U, chi-square) were utilized to determine between-group differences in knowledge gained, quit intentions, and quit attempts at follow-up. Descriptive and correlational analyses were conducted to describe patient perceptions of IPE care.

Results: Fifty patients were enrolled [IPE (n = 25), SC (n = 25)]. The mean age was 48.02 (±12.93). The majority of patients were female (64%), Black/African-American (66%), Non-Hispanic/Latino (80%), smoked cigarettes for an average of 20.61 years (± 12.54), and had made at least one prior quit attempt (68%). IPE patients reported more knowledge gained immediately post-appointment and at four-week follow-up (median composite score 28 versus 13, respectively; p < 0.001 and 30 versus 25; p = .009); Although there was no statistically significant difference in the number of quit attempts at the four-week follow-up, IPE patients that attempted to quit reported a higher incidence of setting a quit date (63.6%) compared to SC patients (20%) (p = .044) and contacting a provider for further assistance with quitting (81.8%) compared to SC patients (40%) (p = .049). The majority of IPE patients (82.6%) were extremely satisfied with their tobacco cessation education and the majority of SC patients were interested in talking with a dentist and pharmacist team about various aspects of tobacco.

Conclusion: Overall, the IPE group reported more knowledge gained regarding tobacco cessation, were more likely to take steps toward quitting, and were satisfied with the IPE care. These findings suggest that a novel interprofessional program between dental and pharmacy students may enhance patient outcomes in the area of tobacco cessation.

Session-Board Number: 2-274

Poster Title: Pharmacists impact on secondary stroke prevention

Primary Author: Olivia Stanton-Ameisen, Temple University School of Pharmacy, Pennsylvania;
Email: tuf22803@temple.edu

Additional Author (s):
Sara Walton
Jennifer Andres
Charles Ruchalski

Purpose: Patients admitted to Temple University Hospital with a cerebrovascular accident (CVA) or transient ischemic attack (TIA) are referred to the pharmacist-run Stroke Prevention Clinic (SPC) for medication management. Once an initial CVA/TIA has occurred, the risk for another event is higher. The goals of the SPC are to reduce hospital admissions for CVAs/TIAs, myocardial infarction (MI), and peripheral artery disease (PAD). Surrogate markers including blood pressure, LDL, and hemoglobin A1c values are tracked. The purpose of this study was to determine if patients receiving SPC care have improved outcomes compared to patients that did not visit the clinic.

Methods: This was a retrospective chart review of patients referred to the SPC. Data was collected from the electronic medical record, EPIC. At the time of CVA/TIA, associated risk factors and pertinent medications were recorded. For patients that attended clinic, the number of appointments with the SPC was recorded and if new medications were added. Blood pressure, LDL, Hemoglobin A1c, and smoking status were collected at the time of CVA/TIA, before initial visit to the SPC, and after last SPC visit. Hospital admissions were reviewed to assess for secondary CVA, MI, and PAD. Data was collected for patients that did not attend clinic visits and was used as a control.

Results: Records were reviewed for 456 patients scheduled over 2 years. Patients that visited the SPC had 4 percent less hospital admissions for CVA/TIA, 1.71 percent less hospital admissions for MIs, and 1.63 percent less hospital admissions for PAD than patients that did not visit the SPC. The primary composite endpoint of readmission for stroke, MI, or PAD occurred in only 9.3 percent of the SPC patients compared to 17 percent in the patients that did not come

to clinic. This composite endpoint was statistically significantly lower in the SPC group (p=0.013). This represents a 43.4 percent relative risk reduction, a 7.4 percent absolute risk reduction, and a number needed to treat of 14. Additionally, all surrogate markers improved in the SPC group.

Conclusion: Improvements in surrogate markers indicate that patients receiving pharmacist intervention in the SPC are more likely to achieve goals than if they did not come to clinic. These results demonstrate that pharmacists in the SPC reduce patient risk factors for secondary CVA/TIA and can prevent future hospital admissions.

Poster Title: Clinical evaluation of fosfomycin use at a community hospital

Primary Author: Jenny Lam, Temple University School of Pharmacy, Pennsylvania; **Email:** jlam415@gmail.com

Additional Author (s):
Joshua Besas
Shimeng Liu
Puja Trivedi
Hien Nguyen

Purpose: Fosfomycin is a broad-spectrum antibiotic administered as a single oral dose for the treatment of urinary tract infections (UTIs) with activity against multidrug resistant (MDR) uropathogens such as extended-spectrum beta-lactamase (ESBL) producing bacteria and carbapenem-resistant Enterobacteriaceae (CRE). In select patients, fosfomycin may help reduce the need for costly intravenous (IV) antibiotics and expedite patient discharge as well as prevent hospital admissions. The purpose of this evaluation is to review the clinical outcomes in patients who received fosfomycin for UTIs. In addition, the economic impact of using fosfomycin will be assessed at our community teaching hospital.

Methods: This retrospective drug use evaluation included patients who received at least one dose of fosfomycin for UTI between January 2013 and December 2015. Patients were identified from a generated report using Discern Analytics in Cerner. Medical records were reviewed and data collection included patient demographics, past medical history, level of acuity, concurrent infections and antibiotics, cultures and susceptibilities, length of stay (LOS), and adverse effects. Reported outcomes included clinical cure, defined as documented infection improvement based on clinical findings and investigator determination, and 30-day UTI-related readmissions or emergency department (ED) visits. The estimated cost avoidance for inpatient days and hospital admissions prevented were also evaluated based on the expected LOS on a case-by-case basis. The institutional review board at Atlanticare Regional Medical Center granted approval for this evaluation.

Results: Twelve patients with an average age of 69 (range 30 to 97 years) were included. Eight of 12 patients were female, 8 had a history of UTI, and 1 had a chronic Foley catheter. Eleven patients were treated on general medical unit with an average LOS of 5.6 days. One patient was treated in the ED and discharged. Results of 9 urine cultures were available for analysis with 3 polymicrobial results. Cultures revealed 6 ESBL producers (4 Escherichia coli and 2 Klebsiella pneumoniae). Other uropathogens identified were CRE Klebsiella, Pseudomonas aeruginosa, non-ESBL Escherichia coli, Enterococcus, and Staphylococcus epidermidis. Five patients had started antibiotic treatment before switching to fosfomycin. After treatment with fosfomycin, 11 of 12 patients achieved clinical cure and 1 patient developed bacteremia secondary to UTI which required IV antibiotic therapy. No patients had a 30-day UTI-related hospital readmission or ED visit and no adverse effects were reported. A total of 39 inpatient days were estimated to be avoided due to 10 early hospital discharges and 1 prevented admission with the use of oral fosfomycin instead of IV antibiotics. This avoided LOS resulted in an approximate cost-savings of 85,800 dollars, or an average savings of 7,150 dollars per patient.

Conclusion: Fosfomycin appears to be an effective, well tolerated, and convenient treatment for patients with UTIs including those caused by MDR uropathogens. In stable patients who are candidates for oral therapy, fosfomycin may be used as a cost-saving option to expedite hospital discharge and prevent hospital admissions. Further pharmacoeconomic studies are warranted to determine the value of fosfomycin in decreasing LOS and hospital admissions.

Poster Title: Drug Use Evaluation of Aspirin 325 mg at a large academic teaching institution

Primary Author: Elona Gjini, Temple University School of Pharmacy, Pennsylvania; **Email:** tue53286@temple.edu

Additional Author (s):
Gary Burdge
Luke Russo
Thien Nguyen
Melissa Rotz

Purpose: The purpose of this drug use evaluation (DUE) is to determine whether aspirin 325 mg is being prescribed appropriately based on guideline recommendations and patient specific risk factors at Temple University Hospital (TUH).

Methods: This DUE was a retrospective patient chart review of all patients admitted into Temple University Hospital (TUH) during July 2015 who received at least 1 dose of aspirin 325 mg. Patients were excluded if they received aspirin 325 mg for pain, rheumatologic diseases, pericarditis, or VTE prophylaxis for orthopedic procedures. The primary objective of this study was to assess the overall appropriateness of aspirin 325mg use at TUH based on guideline recommendations. The secondary outcome aimed to evaluate the safety of aspirin 325 mg based on whether or not bleeding occurred. Risk of bleeding was assessed by calculating a CRUSADE bleeding score for each patient.

Results: 64 patients were screened and 54 were included. Aspirin was used most frequently for acute management of ACS and CAD. Based on the appropriateness criteria, 35 patients (65%) appropriately received aspirin 325 mg and 19 patients (35%) inappropriately received aspirin 325 mg. For the 19 deemed inappropriate 18 (95%) were contrary to guideline recommendations for each specific indication. One patient (2%) experienced a bleed during their hospital stay.

Conclusion: There is certainly a modest degree of inappropriate prescribing of aspirin 325 mg at TUH. The majority of guideline recommendations preferentially recommend low-dose aspirin

over aspirin 325 mg due to its propensity to cause bleeds without any added efficacy. Future practice at TUH should reflect these guidelines, as evidence continues to show that that the risks of high dose aspirin outweigh any benefits.

Poster Title: Evaluation of the use of ceftaroline at Temple University Hospital

Primary Author: Danielle LaPrad, Temple University School of Pharmacy, Pennsylvania; **Email:** tuf18995@temple.edu

Additional Author (s):
Bhamini Patel
Victor Phan
Peter Nikolos
Jason Gallagher

Purpose: Ceftaroline is a relatively new antibiotic; therefore, many off-label uses are being implemented in clinical practice. This DUE was executed to assess how clinicians are using ceftaroline fosamil at Temple University Hospital (TUH), along with the incidence of C. difficile infection.

Methods: This was a retrospective chart review of patients 18 years and older who received at least 24 hours of ceftaroline therapy between August 2014 and September 2015 at TUH. Renal function, organisms, culture-sensitivity data, indications, doses, and incidence of C. difficile infection were collected from medical records. The primary outcome was to assess organisms, indications, doses, and appropriateness of renal dosage
adjustments of ceftaroline at TUH. The secondary outcome was to evaluate the occurrence of C. difficile infection from the start of therapy to seven days after the end of therapy.

Results: 56 patients were screened and 47 were included. A total of 55 organisms were found in cultures, 40 (72.7%) of which were S. aureus (38 MRSA & 2 MSSA). The most common indication was bacteremia (31 patients [45.6% of indications]). Thirty-seven patients (78.7%) received a dose of 600 mg; 23 received 600 mg every 8 hours and 13 received 600 mg every 12 hours, indicating an interval of every 8 hours is used more frequently. Thirteen patients (27.7%) had a CrCl less than or equal to 50 mL/min, 7 of which received an appropriately adjusted dose, while 6 did not. C. difficile infection only developed in 1 patient.

Conclusion: Our data indicate that ceftaroline was used most commonly for S. aureus infections, specifically MRSA. At TUH, it is most commonly used for bacteremia and given more frequently than indicated by FDA. Ceftaroline is not being sufficiently dose adjusted for renal impairment and C. difficile infection is not common. These results suggest that clinicians need to be educated on dose adjusting ceftaroline in renal impairment.

Poster Title: Evaluation of basiliximab induction therapy in nonrenal solid organ transplantation

Primary Author: Lauren Schmidt, Temple University School of Pharmacy, Pennsylvania; **Email:** tuc48540@temple.edu

Additional Author (s):
Maggie McIntyre
Tenielle Watkins
Melanie Zaniewski
Nicole Sifontis

Purpose: Basiliximab is FDA approved for the prophylaxis of acute rejection in de-novo renal transplant recipients, but is often used off-label in nonrenal transplant recipients who may have relative contraindications to more potent lymphocyte depleting agents or do not meet criteria to forgo induction. Based on increasing use at Temple University Hospital, we evaluated the appropriateness of use of basiliximab in the heart, lung, liver, and combined solid organ transplant populations.

Methods: This was a retrospective chart review of all patients admitted from January 2011 to June 2015 who received at least one dose of basiliximab for induction therapy for a nonrenal transplant. The primary objective was to determine the appropriate use of basiliximab in nonrenal transplant recipients as it relates to appropriate dosing, administration regimen, and patient selection criteria based on internal transplant protocols. At 1 year post-transplant, the secondary outcomes evaluated incidence of rejection, Hepatitis C recurrence in liver recipients only, malignancy, and patient survival.

Results: Of 324 patients, the first 59 were included in the study. Overall incidence of appropriate use was seen in 27/59 (45.8%) of patients in the total transplant population. Of those patients deemed inappropriate, the most frequent cause was inappropriate timing of therapy, seen in 18/59 (30.5%) patients, followed by protocol driven indication and inappropriate dosing, seen in 14/59 (23.7%) and 9/59 (15.3%) patients, respectively. 11/59 (18.6%) patients experienced rejection, 2/10 (20%) experienced a recurrence of Hepatitis C,

2/59 (3.4%) patients experienced post-transplant malignancy, and 1/59 (1.7%) patients died within 1 year post-transplant.

Conclusion: Our data showed there were deviations from basiliximab induction protocol in dosing, time of administration, and clinical indication in nonrenal transplant recipients. These results suggest a need to reassess adherence to the protocol. The implementation of a bar coding system would provide global communication of an ordered medication between physicians, pharmacy, and nursing, thus reducing protocol deviations and adverse events.

Submission Category: General Clinical Practice

Submission Type: Evaluative Study

Poster Title: Analysis of national health insurance formularies for treatment of hepatitis C virus infection

Primary Author: Amanda Hall, Temple University School of Pharmacy, Pennsylvania; **Email:** tuf24364@temple.edu

Additional Author (s):
Courtney Conrad
Hamad Juboori
Jennifer Andres

Purpose: With the emergence of novel and highly efficacious direct-acting antivirals (DAAs) for treatment of hepatitis C virus (HCV) infection, it is crucial for physicians and pharmacists to understand the limitations of patients' private insurance coverage. Insurance companies may be reluctant to provide coverage for HCV treatment, due to the cost of these medications. Information regarding private insurance coverage for HCV treatment is lacking, and it is unclear which regimens are preferred by insurance companies. The purpose of this research is to provide insight into common limitations private insurance companies impose on HCV treatments via formulary analysis.

Methods: Focusing on treatment options for treatment-naïve patients with genotype 1 HCV, national private insurance formularies accessed online from January 2016 to May 2016 were examined to assess potential coverage limitations. Data from Kaiser was used to determine the top three national insurance companies by enrollment in each state. The following DAAs were included in the formulary analysis: daclatasvir, sofosbuvir, ledipasvir/sofosbuvir, simeprevir, telaprevir, boceprevir, elbasvir/grazoprevir, and ombitasvir/paritaprevir/ritonavir/dasabuvir. Formularies were assessed for the following parameters: preferred regimen designation, prior authorization requirement, tier location, quantity limit designation, specialty pharmacy designation, and year of last formulary update. HCV treatment guidelines from the time of review were consulted and compared with the results of the formulary analysis to determine if insurance companies' contained complete, preferred regimens.

Results: A total of 81 companies were identified, with 49 of the companies having accessible formularies. Forty-eight out of the 49 (98%) formularies analyzed had been updated for 2016. Overall, greater than 80% of the formularies denoted that DAAs required prior authorization, and over 75% of formularies explicitly classified these agents as specialty medications. Elbasvir/grazoprevir, telaprevir, boceprevir were found to be included in the fewest number of formularies; whereas, ledipasvir/sofosbuvir and sofosbuvir were found to be included in the most formularies. Ledipasvir/sofosbuvir was found to be the preferred, first-line, treatment regimen among available DAAs, but there was great variance between formularies when it came to information provided, parameters, and preferences.

Conclusion: In general, private health insurance formularies are easily accessible by an internet search, and they provide information, albeit limited, regarding their coverage of medications. From the information garnered as a result of formulary analysis, it is possible to draw conclusions and make predictions about which medications may be more easily obtained. Although the formularies evaluated offer some insight into coverage of HCV treatment options, it still remains unclear as to what specifications must be met by patients and healthcare providers in order for the patient to receive treatment with any of these medications.

Poster Title: Quality assessment of pharmacist-managed warfarin therapy at Temple medicine group practice

Primary Author: Joyce Gambrah, Temple University School of Pharmacy, Pennsylvania; **Email:** tuf09044@temple.edu

Additional Author (s):
Danielle LaPrad
Bhamini Patel

Purpose: Warfarin is a medication that requires routine monitoring of the international normalized ratio to make sure it is being used safe and effectively. In January 2015, the pharmacists at Temple Medicine Group Practice initiated a formal follow-up for patients missing international normalized ratio appointments. The purpose of this study was to compare the management of warfarin therapy before and after implementation of the formal follow-up

Methods: This study was a retrospective chart review of patients on warfarin who were actively followed by a pharmacist from January 2014 to December 2014 (before follow-up) and from January 2015 to December 2015 (after follow-up). Outcomes evaluated were: percentage of therapeutic international normalized ratio values, percentage of therapeutic international normalized ratios plus/minus 0.2, numbers of missed appointments, and number of patients having their international normalized ratios checked at least every four weeks.

Results: A total of 45 patients were included. Mean age was 61 and most patients were on warfarin for atrial fibrillation or history of venous thromboembolism. Percentage of therapeutic international normalized ratios was 49.9% in 2014 and 46.9% in 2015 (P= 0.33). Percentage of therapeutic international normalized ratios plus/minus 0.2 was 62.9% in 2014 and 60.3% in 2015 (p= 0.36). The number of missed appointments decreased from 6.6 to 5.1 (p=0.03) and international normalized ratios done at least every 4 weeks increased from 22% to 27% (p=0.41).

Conclusion: Percentage of therapeutic international normalized ratios were suboptimal and did not improved in 2015.

Poster Title: Physiologically Based Pharmacokinetic Modeling Using SIMCYP Predicts Sertraline Exposure in Pregnant Patients

Primary Author: Naveen Daryani, University of Pittsburgh, Pennsylvania; **Email:** nmd42@pitt.edu

Additional Author (s):
Hari Kalluri
Rujuta Joshi
Steve Caritis
Raman Venkataramanan

Purpose: Sertraline is approved for the treatment of depression and is primarily metabolized by CYP2D6 and CYP3A4, and is also renally excreted. Activity of CYP2D6, CYP3A4, and glomerular filtration rate increase in pregnancy. This is expected to decrease exposure of sertraline and its therapeutic effect. Our objective is to predict exposure of sertraline during pregnancy using physiologically based pharmacokinetic (PBPK) modeling, so that necessary dose adjustments can be made in pregnant women.

Methods: Full PBPK modeling and simulations were conducted using SIMCYP V15 simulator. Data for physiochemical properties, absorption, distribution, metabolism, and elimination were obtained from published literature or from population prediction using SIMCYP. Sertraline exposure was evaluated in 10 virtual healthy patients using a single 100 mg dose over 72 hours. The model was then validated by evaluating the exposure of a single 100 mg dose over 120 hours in 10 independent virtual patients. Then using the virtual pregnant population in SIMCYP, simulations were conducted to determine sertraline plasma concentration time profiles at various gestational weeks.

Results: Models correctly assessed sertraline pharmacokinetics and accurately predicted sertraline exposure in both healthy volunteers and in the pregnant population. In the first observed study of a single 100 mg dose monitored over 72 hours, there was a 4.5% difference in the Tmax, a 9.5% difference in the Cmax, an -8.7% difference in the AUC, and an 8.1% difference in the Cl/F when compared to the model predictions. In the second study used to

validate the model, a single 100 mg dose monitored over 120 hours was seen to have a 9.9% difference in the Tmax, a 9.7% difference in the Cmax, a 0.207% difference in the AUC, and a -.207% difference in the Cl/F, when compared to the model predictions. In the simulated pregnant population, at 8-15 hours post dose, after the drug has reached steady state, the PBPK model predicted a decrease in the concentration: dose ratio of 27.8%. This is similar to the decreased reported concentration: dose ratio of 40% in a published study of 6 pregnant women on sertraline.

Conclusion: A new robust model was built and validated using single dose administration of 100 mg of sertraline in healthy volunteers. Dosing adjustments can be made after using the model to predict the exposure of the drug. This model can now be used to make predictions at steady state in pregnant patients to optimize therapeutic effects of the drug at various gestational ages to combat physiological changes that occur during pregnancy.

Poster Title: Implementation of a pharmacist-based renal monitoring and dosing program in a community hospital: Outcomes one month later

Primary Author: Carolyn Ubinger, University of Pittsburgh, Pennsylvania; **Email:** cru3@pitt.edu

Additional Author (s):
Jennifer Fever

Purpose: Impairment in kidney function affects pharmacokinetic parameters such as renal drug elimination, which may result in suboptimal drug dosing. During a hospital stay, a patient's renal function may change due to disease state or kidney damage. Many medications have recommended doses specific to markers of kidney function to ensure its safe and efficacious use. A renal monitoring and dosage adjustment policy was implemented to facilitate pharmacist-based management of targeted medications in a community hospital.

Methods: A targeted list of medications that may warrant dose adjustment in patients with decreased renal function were defined with specific dosing guidelines for each medication. High risk patients who were more likely to require renal dose adjustments were determined based on age, serum creatinine, and calculated creatinine clearance. On a daily basis, pharmacists reviewed these patients through the electronic health record to evaluate the appropriateness of the dosing for targeted medications utilizing the estimated creatinine clearance calculated by the Cockcroft-Gault equation. Pharmacists also considered the indication for the medication, severity of illness, duration of medication use, and other markers of renal function such as blood urea nitrogen and urine output when assessing the medication dosage. A procedure was outlined through which pharmacists were able to directly adjust these medication orders automatically by protocol or through communication with the prescriber based on the specific medication if necessary based on the patient's renal function. Through the protocol pharmacists were also able to order serum creatinine levels to be drawn to ensure appropriate monitoring of the patient's renal function. The pharmacists documented the medications that were reviewed and any interventions made in the patient's electronic health record.

Results: In one month, a total of two-thousand two-hundred and sixty-eight medication orders were reviewed by pharmacists through the protocol. The most frequently reviewed

medications were famotidine, cefepime, and vancomycin which comprised approximately twenty percent, twelve percent, and eleven percent of all orders reviewed respectively. Of the twenty-nine medications included in the protocol, six medications were not ordered for patients within this time frame, including amikacin, cefotaxime, pamidronate, streptomycin, tobramycin, and zoledronic acid. Of the medication orders that were reviewed, two-thousand and fifty-five orders were appropriately dosed based on the patient's renal function. A total of one-hundred and ninety medication doses were changed by pharmacists through the protocol; one-hundred and seventeen doses were decreased and seventy-three doses were increased. Of the doses that were adjusted, approximately fifty-six percent were changed on the first dose of the drug that was ordered for the patient and approximately forty-four percent were changed on a later dose of the drug. The dose of a given medication was changed through the protocol multiple times within a single patient encounter for twenty-four patients. Prescribers opted-out of the pharmacist renal dosing protocol for twenty-three drug orders during the month.

Conclusion: A pharmacist-based renal dosing protocol was successfully implemented in a community hospital, allowing medication orders to be reviewed through a systematic approach. Patient-specific characteristics were used to inform the pharmacist if medication dosing changes were necessary. Numerous dosing changes were made during the first month after protocol implementation, proving the impact pharmacists can have on renal medication dosing.

Poster Title: Assessing off-label medication use in the ICU that diverges from guideline recommendations

Primary Author: Stephanie Tchen, University of Pittsburgh School of Pharmacy, Pennsylvania;
Email: stt33@pitt.edu

Additional Author (s):
Bethany Shoulders
Sandra Kane-Gill
Pamula Smithburger

Purpose: Over 40% of medications administered in the intensive care unit (ICU) are off-label. Off-label medication use signifies that the US Food and Drug Administration (FDA) does not approve of specific indications, doses, routes, or populations. Guidelines and consensus statements function to provide an evidence evaluation that advises clinicians on safe and effective off-label medication use; however, scenarios exist in clinical practice that are inconsistent with guideline recommendations. The aim of this evaluation is to determine the frequency of off-label medication use without support by guidelines and consensus statement recommendations and explore the reasons behind these inconsistencies.

Methods: Off-label medication use for indications in the medical ICU was assessed in three academic centers over a three-month period. Separate PubMed and National Guideline Clearinghouse searches were conducted to find relevant guidelines or consensus statements on the identified off-label indications. Following a review by two individuals (ST, BS), medication uses that were found to be inconsistent with recommendations were included in this evaluation. These recommendations were evaluated for explanations why guidelines did not support use in practice. These included the potential for adverse drug reactions, availability of superior agents, or lack of efficacy.

Results: One hundred forty-four off-label medication indications were identified as having 253 guidelines with recommendations. Eleven percent (27/253) of guidelines or consensus statements contained recommendations which were inconsistent with the off-label medication use in practice. Of the recommendations that provided grading, 33% (7/21) of medications had

a strong recommendation against its use for the indication. Some guidelines cited multiple reasons for advising against the use of the medication indication. The most common reason for not recommending an off-label medication was due to the lack of clinical efficacy for the medication for the indication (37%, 10/27). Other reasons included the potential for adverse drug reactions (30%, 8/27), the lack of evidence for providing a recommendation (22%, 6/27), the availability of superior agents (7%, 2/27), and other miscellaneous reasons (15%, 4/27). Of interest, 25% (6/24) of off-label medications indications also had conflicting guidelines that did support the off-label use.

Conclusion: Use of unsupported off-label indications should be heavily weighed for risks versus benefits as a majority of indications show a lack of efficacy and increase the risk for adverse drug reactions. This evaluation also recommends that clinicians look at multiple guidelines and consensus statements in making decisions as conflicting evidence may be identified.

Poster Title: The role of student pharmacists in evaluating drug therapy problems in dual diagnosis patients

Primary Author: Meaghan Herbick, University of Pittsburgh School of Pharmacy, Pennsylvania; **Email:** mmh72@pitt.edu

Additional Author (s):
Stephanie Tchen
Lauren Jonkman

Purpose: Patients with dual diagnosis are vulnerable to drug therapy problems. Drug therapy problems (DTPs) are defined as events involving medication therapies that result in undesirable effects for the patient, interfere with goals of therapy, and require professional judgment to resolve. Pharmacists play an important role in identifying and resolving DTPs, and are underutilized when working with dual diagnosis. The objective of this analysis is to describe common DTPs found in a dual diagnosis patient population receiving services at a drug and alcohol treatment program in Pittsburgh, Pennsylvania. Further, we aim to determine the prevalence of abusable substances in this population.

Methods: The pharmacy team consisted of two fourth year student pharmacists on an advanced practice pharmacy experience (APPE) and a pharmacist preceptor. In this quality improvement project, patients at the Salvation Army Harbor Light Center were included if they were seen by the pharmacy team for medication therapy management and medication education between May 9, 2016 to July 22, 2016. DTPs from the visits were identified and analyzed on the basis of type and rate of occurrence. Medications included as "abusable" included gabapentin, quetiapine, and buproprion. Data was analyzed using descriptive statistics.

Results: A total of 17 patients were included with 51 drug therapy problems identified (average 3 DTP/pt). The most prevalent drug therapy problem was noncompliance (71%). Other common drug therapy problems were lack of understanding (65%), needs additional drug therapy (53%), and adverse drug event (29%). Patients were on an average of 6 medications (range 1-10) Common concomitant psychiatric disorders of these dual diagnosis patients included

depression (59%), bipolar disorder (59%), and anxiety (35%). Out of the 17 patients seen by the pharmacy team, 53% were prescribed potentially abusable medicines (gabapentin, quetiapine, bupropion).

Conclusion: Based on the results of this small population, patients with dual diagnosis have important DTPs and can benefit from further pharmacist involvement and additional medical attention. Care should be taken to adequately educate these patients on their medications, their disease states, and the importance medication adherence. They should also be made aware of various medication adherence tools including mobile applications, alarms, pillboxes, and dose packages in order to improve medication compliance. The high rate of potentially abusable medications in this population is quite worrisome.

Poster Title: Proton Pump Inhibitor Adjuvant Combinations for the Management of Typical and Extraesophageal Gastroesophageal Reflux Disease: A Systematic Review

Primary Author: Jing Zhu, University of Pittsburgh School of Pharmacy, Pennsylvania; **Email:** jiz91@pitt.edu

Additional Author (s):
Patrick Squires
Michele Klein-Fedyshin
Sandra Kane-Gill

Purpose: Gastroesophageal reflux disease (GERD) is the most common principal gastroenterological diagnosis in the United States, manifesting as a broad spectrum of disease with varying typical and extraesophageal presentations. Treatment for GERD classically encompasses management strategies beginning with lifestyle modifications then escalating to pharmacologic, and finally, surgical intervention. Proton pump inhibitors (PPIs), remain the mainstay of GERD treatment although approximately 40% of patients are refractory to PPIs alone, inducing the need for more aggressive pharmaceutical treatment modalities. The purpose of this systematic review is to assess objective and subjective GERD outcomes of PPI adjuvant combinations compared to PPI treatment alone.

Methods: Databases of MEDLINE, EMBASE, and Cochrane, were searched from 1946 through May 20, 2016 using prespecified search terms and key words including but not limited to: gastroesophageal reflux disease, extraesophageal reflux, combinations, antacids, H2 receptor antagonists, proton pump inhibitors, muscle relaxants, cytoprotective barrier agents, and pain modulators. We applied the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines for systematic reviews and developed PICO (population, intervention, comparison, and outcome) questions using GRADE (grading of recommendations, assessment, development and evaluation). Abstracts were screened for the following inclusion requirements: randomized clinical trials, nonrandomized intervention studies, observational studies, age ≥ 18 years, humans, full-text articles, and English language. All abstracts were reviewed independently by two reviewers using an online reference management system (DistillerSR) until the reviewers reached adequate agreement (kappa score ≥0.90). Full text

articles of the selected abstracts required either a typical or extraesophageal GERD patient population with pharmacologic PPI adjuvant combination intervention and a PPI comparator arm.

Results: Literature searches using the criteria described above yielded 7084 references and 49 articles were deemed appropriate for further review. Four studies were excluded upon full text review leaving 45 articles for inclusion. Of the 45 articles, there were three GERD population subsets: 30 typical reflux, 8 extraesopahgeal reflux, and 7 mixed typical and extraesophageal reflux. Additionally a total of 24 studied a PPI refractory population defined as troublesome symptoms despite once daily PPI and the other 21 articles did not specify. The 45 articles addressed five therapeutic mechanisms of action including: antisecratory acid suppression (8), prokinetic motility (22), transient lower esophageal sphincter relaxation inhibition (8), cytoprotective barrier protection (5), and pain modulation (2). A total of 37 investigated some form of quality-of-life measure utilizing 20 different scales with the most frequent scales utilized being the frequency scale for the symptoms of GERD (7) and gastrointestinal symptom rating scale (5). The combination adjuvant treatment group as a whole demonstrated significant quality-of-life improvement over PPI alone in 15/37 (41%) studies. A total of 12 articles investigated total esophageal pH % time < 4 of which overall the addition of an adjuvant agent resulted in 6/12 (50%) demonstrating statistically significant improvements.

Conclusion: Currently in the literature there exists much heterogeneity in patient populations studied, quality-of-life symptom questionnaires, and objective pH measures used to evaluate therapeutic success of GERD. Adjunctive combinations of pharmacologic agents known to combat GERD may play a role in aiding patients intolerant or unwilling to elect anti-reflux surgery. More specifically, any adjunctive agent that may negate reflux symptoms could be helpful to those with difficult-to-treat subtypes of GERD such as refractory and extraesophageal manifestations.

Poster Title: Assessing the impact of initiating an intravenous narcotic dose rounding program on patient safety and cost saving benefits in a large academic hospital setting

Primary Author: Tyler Hoffman, University of Pittsburgh School of Pharmacy, Pennsylvania; **Email:** tdh23@pitt.edu

Additional Author (s):
Alfred L'Altrelli
John Cadwalader

Purpose: Initiating a dose rounding program for narcotic intravenous medications, specifically hydromorphone, is a program intended to prevent errors, improve patient safety, reduce wasted drug product and nursing labor, resulting in a net cost savings to the health system. This study was initiated to evaluate the potential benefits of an intravenous hydromorphone dose rounding protocol University of Pittsburgh Medical Center Presbyterian Hospital.

Methods: Patient and medication dosing data was collected using QUESTVISTA and CERNER to quantify the distribution of doses. Data was reviewed and categorized to determine how many doses were appropriate candidates for future dose rounding considerations. Pharmacy team members at University of Pittsburgh Medical Center Presbyterian Hospital and the University of Pittsburgh Medical Center Pharmacy and Therapeutics committee determined ideal dosage ranges and corresponding appropriate rounded doses of based on clinical expertise. The rounding parameters approved by the committee included: dosing ranges 0-0.3 mg rounded to 0.25mg, 0.31-0.6 mg rounded to 0.5mg, 0.61-0.8 mg rounded to 0.75mg, 0.81-0.19 mg rounded to 1 mg, 1.2-1.75 mg rounded to 1.5mg, and 1.76-2.4mg rounded to 2mg. The primary endpoint of the analysis was to determine the percentage of doses which required nurse wasting. The secondary was calculated estimated cost savings from dose rounding strategies based on production of large batched doses using automated technology, reducing pharmacy labor as well as reduction in potential risk for error. There would still be potential patient populations not associated with the dose rounding program, including doses for the Post-Anesthesia Care Unit and any frail, elderly patients who are older than 75 years of age and also weight less than 60 kilograms.

Results: The data showed that out of 160,433 prescribed and administered doses of intravenous hydromorphone, 134,108 doses (84%) of all doses were partial doses requiring waste. 26,325 doses (16%), were dosed as whole syringe volumes. Nurse time wasting a dose is estimated at 3-5 minutes per dose, averaging at 4 minutes per dose for a total of 8940 hours per year spent wasting doses. The numbers and percentages of rounded doses of the total 158,327 doses were 85,592 doses (54%) rounded to 0.25mg, 43,680 (27.6%) rounded to 0.5mg, 1,183 (0.8%) rounded to 0.75mg, 23,556 (14.9) rounded to 1mg, 2,184 (1.4) rounded to 1.5mg, and 2,132 (1.3) rounded to 2mg. Notable excluded groups were patients greater than 75 years and less than 60 kg, and patients from the Post-Anesthesia Care Unit.

Conclusion: University of Pittsburgh Medical Center Presbyterian Hospital had to waste partial doses of hydromorphone after 84% of annual intravenous hydromorphone administrations. By rounding intravenous hydromorphone doses to standardized preapproved doses compared to previous practices of allowing prescriber preference, the hospital will be able to decrease medication errors and improving patient safety while simultaneously reducing costs to the health system.

Poster Title: Analysis of Tramadol Use in A Pediatric Tertiary Care Population

Primary Author: Ingrid Pan, University of Pittsburgh School of Pharmacy, Pennsylvania; **Email:** inp3@pitt.edu

Additional Author (s):
Denise Howrie
Carol Vetterly
Marian Michaels

Purpose: Tramadol, a centrally acting synthetic opioid analgesic, is not currently FDA-approved for use in the pediatric population, although it has been used for post-operative pain, most notably after tonsillectomy or adenoidectomy. An FDA Med Safety Communication in September 2015 highlighted intent to evaluate possible risks in children, especially in ultra-rapid metabolizers, who may generate higher plasma O-desmethyltramadol concentrations, increasing risk of respiratory depression. The purpose of this project was to determine frequency of tramadol use and analyze patterns of prescribing at the Children's Hospital of Pittsburgh of UPMC (CHP).

Methods: This project was approved by the University of Pittsburgh Medical Center (UPMC) Quality Improvement Review Committee. A retrospective chart review was conducted in patients identified from electronic health records ages ≤ 17 years treated with 1 or more tramadol doses during hospitalization during a 12 month period. Patient data collection included demographics (age, weight, disease state, MD prescribing service), dosage regimen (dose, frequency, duration of treatment), stated indication for prescribing, use of other analgesics, and medication allergy.

Results: A total of 70 pediatric patients were identified. Median patient age was 15 years, with age distribution of 11 children ≤12 years (16%) and 44 (63%) ages 12-16 years. The most frequent physician prescribing services were Pain Management Services (49% orders, n=34) and Rheumatology Services (23%, n=16). Tramadol was prescribed "as needed" rather than as a scheduled analgesic agent (81%, n= 57). Notable was tramadol use for non-surgical pain

management (86%, n=60), rather than following surgical procedures. Median single doses were slightly higher in patients ≤ 12 years vs. patients 12 to 17 years (1.1 mg/kg vs. 0.8 mg/kg).

Conclusion: A recent FDA warning reported intent to evaluate tramadol use, highlighting risk of respiratory depression in post-operative pediatric settings such as tonsillectomy, possibly due to ultra-rapid drug metabolism. However, in this tertiary pediatric institution, tramadol was most frequently prescribed as opioid alternatives for non-surgical pain management. Greatest drug use appeared more in the setting of chronic pain management, as demonstrated by 2 predominant prescribing services and utilized an "as needed" frequency for dose titration. This evaluation confirms tramadol prescribing occurs across pediatric ages, with most common use in the adolescent population and in the setting of chronic pain conditions.

Poster Title: Impact of selective serotonin reuptake inhibitor (SSRI) treatment on major adverse coronary event incidence in patients receiving dual antiplatelet therapy after percutaneous coronary intervention

Primary Author: Puja Patel, University of Pittsburgh School of Pharmacy, Pennsylvania; **Email:** pup1@pitt.edu

Additional Author (s):
James Coons
Kyle Zacholski
James Stevenson

Purpose: Dual antiplatelet therapy, consisting of a P2Y12 inhibitor and aspirin, is prescribed after percutaneous coronary intervention (PCI) to prevent major adverse cardiac events (MACE). Patients receiving percutaneous coronary intervention often have comorbid depression, which is associated with poorer cardiac prognosis. Selective serotonin reuptake inhibitors (SSRIs), which are first line pharmacotherapy for depression, inhibit the uptake of serotonin into platelets, which may reduce platelet aggregation. The aim of this study was to assess if the use of (SSRIs) in this patient population affected MACE incidence.

Methods: In this retrospective study, eligible patients were identified by ICD-9 code and outpatient procedure codes for percutaneous coronary intervention during the study period of July 1, 2010 to December 31, 2013 at the University of Pittsburgh Medical Center (UPMC) Presbyterian hospital. Antidepressant use was identified by inpatient hospital administration charges and the primary endpoint was MACE incidence at 1 year. To avoid confounding by P2Y12 inhibitor, we only included patients treated with clopidogrel, which was the most common agent in its class during this time period. Depression is an established risk factor for coronary events, so to prevent reversal causality, we used patients receiving the non-SSRI antidepressant mirtazapine as our comparator group. Mirtazapine has no appreciable effect on the serotonin transporter and is not known to be cardio-protective or cardiotoxic. MACE was defined as a composite outcome of cardiovascular death, non-fatal MI, stroke, and target vessel revascularization. Student's t-test and chi square test with an alpha of 0.05 were used to

analyze baseline characteristics and perform crude analysis of MACE incidence by medication group. A binary logistic regression model was used to adjust for clinical covariates.

Results: A total of 875 patients were included (SSRI n=812, mirtazapine n=63) and one-year major adverse coronary event (MACE) incidence was 21.7% (n=190). In crude analysis, selective serotonin reuptake inhibitor (SSRI) patients had reduced odds of major adverse coronary event (MACE) (OR 0.49, 95% CI 0.28-0.84, p=0.008). In a logistic regression model adjusted for age, sex, diabetes, heart failure, dyslipidemia, stroke, kidney disease, and valvular disease, SSRI use was suggestive of a protective effect although the association was not statistically significant (OR 0.58, 95% CI 0.32-1.03, p=0.06). In a secondary analysis excluding patients on the CYP2C19 inhibitors fluoxetine and fluvoxamine (n=92), SSRIs were protective in crude (OR 0.48, 95% CI 0.28-0.83, p=0.01) and adjusted analyses (OR 0.56, 95% CI 0.31-0.99, p=0.05).

Conclusion: With the exclusion of fluoxetine and fluvoxamine from the adjusted analysis, selective serotonin reuptake inhibitors showed a protective major adverse coronary event (MACE) effect in this patient population. Further studies will be done to assess long term and short-term effects on major adverse coronary event (MACE) incidence.

Submission Type: Evaluative Study

Session-Board Number: 2-289

Poster Title: Impact of SSRI treatment on bleeding outcomes in patients receiving dual antiplatelet therapy after percutaneous coronary intervention

Primary Author: Kyle Zacholski, University of Pittsburgh School of Pharmacy, Pennsylvania; **Email:** kaz42@pitt.edu

Additional Author (s):
James Stevenson
Puja Patel
James Coons

Purpose: Dual antiplatelet therapy, consisting of a P2Y12 inhibitor and aspirin, is effective for prevention of ischemic events in patients who undergo a percutaneous intervention (PCI) but increases the risk of bleeding. Selective Serotonin Reuptake Inhibitors are frequently used for affective and anxiety disorders that commonly co-occur with coronary artery disease. An increased risk of bleed in patients taking SSRIs has been demonstrated in some patient populations but has not been adequately examined in the context of dual antiplatelet therapy. Serotonin is a mediator of platelet aggregation, and SSRIs inhibit the uptake of serotonin by platelets thus potentially increasing bleeding risk.

Methods: This study was a retrospective analysis of the electronic medical record system at the University of Pittsburgh Medical Center (UPMC) Presbyterian. Patients were identified by ICD-9 code for PCI procedure or outpatient code. Patient antidepressant use and non-use was determined by inpatient medication charge codes for administration. Only patients taking clopidogrel were included in the analysis. The primary endpoint was any bleed within 30 days of the PCI procedure. The secondary endpoint was any bleed within one year of the procedure. Clinically significant bleeds were defined using a modified TIMI and GUSTO criteria. Baseline characteristics were analyzed using the student's t-test and chi square test. A multinomial logistic regression model was used to assess the incidence of bleed at 30 days and one year with a significant P-value of less than 0.05

Results: Of 6874 patients who underwent PCI from July 2010 to December 2013 started on dual antiplatelet therapy with clopidogrel, 6062 patients were not on an SSRI and 812 patients were

on an SSRI. In a model of 30-day bleed incidence, adjusted for age, race, gender, and the history of the following: hypertension, dyslipidemia, heart failure, chronic obstructive pulmonary disease, chronic kidney disease, prior coronary artery bypass graft, and prior valve replacement, there was a statistically significant incidence of bleeding events in 1 year in the SSRI group $p=0.033$ (OR 1.21; 1.02-1.44). There was no difference in bleeding incidence at 30 days $p=0.58$ (OR 1.09; 0.81-1.45).

Conclusion: Selective Serotonin Reuptake Inhibitors were not associated with additional bleed incidence in the 30-day post-PCI period. At one year, there was a 20% greater incidence of bleeding events in the SSRI group, suggesting additional caution and risk to using SSRIs in patients already at a higher risk of bleed on dual antiplatelet therapy.

Poster Title: Weight-Based Antimicrobial Agents in Obese Patients: A Focused Literature Review of Pharmacokinetic and Clinical Data Across Obesity Classifications

Primary Author: Brian Aston, University of Pittsburgh, School of Pharmacy, Pennsylvania; **Email:** bca10@pitt.edu

Additional Author (s):
Daniela Policicchio
Brian Potoski

Purpose: The prevalence of obesity has shown an increasing trend in American adults from 1999 through 2014 according to the US Department of Health and Human Services. Antimicrobials that are dosed on a milligram per kilogram (mg/kg) basis can have altered pharmacokinetic (PK) parameters in the obese that may increase toxicity or affect outcomes. This literature evaluation was conducted to determine relevant gaps in data regarding antimicrobial dosing in the obese.

Methods: A systematic review of current literature was conducted using PubMed and Ovid MEDLINE databases, and ClinicalTrials.gov was queried to assess ongoing or future studies. The antimicrobial agents evaluated included: Colistin/Colistimethate, Daptomycin, Quinupristin-Dalfopristin, Sulfamethoxazole-Trimethoprim, Voriconazole, and Acyclovir. Studies were evaluated and grouped based on two categories: case reports and clinical trials versus PK studies. Obesity classifications among subjects were evaluated in clinical and PK studies (BMI-based Class I, II, and III obesity or percentage of ideal body weight). PK studies were specifically evaluated based on parameters measured. Data from an academic medical center that stratified patients by BMI were also evaluated for obesity prevalence (BMI ≥ 30).

Results: Fourteen studies, comprising 357 subjects, were identified across all antimicrobial agents. Of these, 6 were PK studies assessing Daptomycin (n=3), Voriconazole, and Acyclovir. All PK studies identified in obese patient populations evaluated standard PK parameters (Cmax, CL, Vd) with the exception of AUC, Tmax and Half-life (T½), which were not evaluated in all 6 studies. Voriconazole lacked any data regarding T½ in the obese population. Quinupristin-Dalfopristin, Sulfamethoxazole-Trimethoprim, and Colistin/Colistimethate lacked any published

PK studies in any obesity classification. In all 14 studies the majority of patients (n=190; 53.2%) were enrolled in Daptomycin studies (n=6), while Sulfamethoxazole-Trimethoprim had no studies involving obese patients. Of the overweight/obese patients evaluated across all studies, overweight patients accounted for 11.2% (n=40); Class I obesity accounted for 38.3% (n=137); Class II obesity accounted for 24.9% (n=89); and Class III/morbid obesity accounted for 25.5% (n=91). Studies of Quinupristin-Dalfopristin only included 11 Class I obese patients. Over half of the studies (64.3%) involved either Daptomycin 42.9% (n=6) or Voriconazole 21.4% (n=3). Sulfamethoxazole-Trimethoprim, Quinupristin-Dalfopristin, and Voriconazole lacked any data in Class III/morbid obesity. Additionally, BMI data collected from an academic medical center between April 2015-March 2016 found that 13.8% (n=42) of obese patients had a BMI ≥ 40kg/m2

Conclusion: Antimicrobial PK studies in the overweight and obese were dramatically lacking, even as obesity prevalence increases. In those few studies conducted, obesity classifications were grouped inconsistently, which may have led to bias by potentially disguising significant PK or outcome related differences. Additionally, all PK studies were conducted using sample collection schemes for normal weight patients, which may present a biased picture of PK parameters in the obese. As the prevalence of obesity continues to increases more studies in this population are warranted along with consistent classifications.

Poster Title: Evaluation of intravenous minocycline utilization at a community teaching hospital

Primary Author: Brianne Traub, University of the Sciences, Pennsylvania; **Email:** btraub@mail.usciences.edu

Additional Author (s):
George Haddad
Anthony Salvia
Raymond Vuong
Joseph Reilly

Purpose: The use of intravenous (IV) minocycline has garnered interest due to its antimicrobial activity against gram-positive and gram-negative bacteria, including multidrug resistant (MDR) Acinetobacter infections. Atlanticare Regional Medical Center (ARMC) added IV minocycline to formulary in July 2015 for the treatment of MDR infections. We conducted a medication use evaluation of patients who have received IV minocycline at ARMC. The objective of this evaluation is to assess each case for appropriate antibiotic utilization and outcomes as a function of our antimicrobial stewardship program.

Methods: Patients included in our study were those admitted to ARMC who received at least one dose of IV minocycline between July 2015 and July 2016. Patients were identified by a report generated from Discern Analytics in Cerner. A retrospective electronic medical record review was performed and data collection included demographics, pertinent past medical history, level of care, length of stay (LOS), source of infection, culture and susceptibilities, and concurrent infections. The IV minocycline dose and duration as well as previous and concomitant antibiotic therapies were recorded. Progress notes were examined to assess the rationale for IV minocycline, and both clinical and microbiologic outcomes were assessed. Clinical cure was determined by investigators based on clinical findings consistent with infection improvement. Microbiologic cure was defined as subsequent negative cultures in evaluable patients. Appropriate antibiotic utilization was determined by investigators on a case-by-case basis considering cultures, susceptibilities, infection type, and past medical history. Antibiotic dose and duration was documented as well as the employment of combination therapy for a given infection. The Institutional Review Board at ARMC granted approval for this project.

Results: Five patients received at least one dose of IV minocycline in our study. Patients had an average LOS of 19 days (range 5-47 days). The average age was 58 (range 28-79 years) and no patients were considered immunocompromised. Acinetobacter was cultured in three patients with two having positive sputum cultures and pneumonia, and one patient with bacteremia confirmed by positive blood cultures. Chryseobacterium was cultured in the blood of one patient. Only two doses of IV minocycline were given empirically for one patient with a wound infection. Clinical cure was demonstrated in four of four patients considered evaluable. Microbiologic cure was observed in all four of these patients, including two bacteremias (one Acinetobacter, one Chryseobacterium) and two pneumonia patients both with Acinetobacter. The most frequent dosing regimen of IV minocycline was 100 mg twice daily with only two patients receiving a 200 mg loading dose. The use of IV minocycline was deemed appropriate in all five patients, although the dosing was considered suboptimal at 100 mg twice daily in four cases. The duration of IV minocycline therapy ranged from 1 to 7 days. The employment of combination therapy was considered underutilized with IV polymyxin B prescribed in one patient.

Conclusion: Intravenous minocycline has been found to be effective for treating patients with MDR infections. Our evaluation demonstrated the value of IV minocycline for Acinetobacter infections in a small number of patients. Our antimicrobial stewardship program recognizes a need for education to ensure dose optimization and consideration for combination therapy when treating MDR infections involving IV minocycline. Further study is warranted to determine the ideal antimicrobial treatment regimen for MDR infections, including Acinetobacter, at our institution.

Poster Title: Telavancin use in patients with a documented vancomycin allergy

Primary Author: Patrick Daniel Mata, University of the Sciences, Pennsylvania; **Email:** pmata@mail.usciences.edu

Additional Author (s):
Anna Marie Kern
Patricia Durkin
Anita Venuto
Joseph Reilly

Purpose: Telavancin is a semisynthetic lipoglycopeptide antibiotic and a derivative of vancomycin. Telavancin is indicated for the treatment of complicated skin and skin structure infections and hospital-acquired and ventilator-associated bacterial pneumonia caused by susceptible Gram-positive bacteria in adult patients. Due to its similar glycopeptide structure, there is concern of cross-reactivity with telavancin in patients who have a documented vancomycin allergy. This report describes three patients with documented vancomycin allergies who were safely administered telavancin for the treatment of Gram-positive infections. Patient 1 was a 42-year-old female weighing 90 kg who experienced respiratory distress requiring treatment following administration of intravenous (IV) vancomycin in 2000. She presented to the emergency department (ED) in 2016 with complaints of generalized pain secondary to sickle cell crisis. She was diagnosed with methicillin-resistant Staphylococcus aureus (MRSA) bacteremia, multidrug resistant Enterobacter cloacae bacteremia, and native mitral valve endocarditis. Her documented antibiotic allergies include ceftriaxone, erythromycin, and vancomycin. Patient 1 was initiated on daptomycin 6 mg per kg. Blood cultures failed to clear on daptomycin despite an increase in treatment dose to 10 mg per kg, the addition of gentamicin, and removal of an infected port catheter. Telavancin 875 mg (9.7 mg per kg) was initiated. The patient was premedicated with diphenhydramine 25 mg IV before telavancin doses. Telavancin was tolerated for the course of therapy without any adverse reactions of infusion related events.
Patient 2 was a 49-year-old female weighing 54 kg who presented to the ED with complaints of abdominal pain status post mechanical injury. She had received vancomycin in the past and developed generalized itching, which resolved after the infusion rate was decreased. After

premedication with IV diphenhydramine 25 mg, patient informed consent was obtained to re-challenge with IV vancomycin at a slower infusion rate. She still experienced a reaction and pruritus with vancomycin infusion. Following the reaction to vancomycin, Patient 2 was switched to telavancin 500 mg (9.25 mg per kg), and no adverse events were reported throughout the 5 day course of therapy.

Patient 3 was a 30-year-old female who presented to the ED from her provider's office with a persistent right foot infection. She weighed 120 kg and had a history of diabetic ulcers that resulted in the amputation of the left foot. She had documentation of an allergic reaction to vancomycin during a previous admission. Wound cultures of the right foot revealed MRSA and Streptococcus agalactiae. She was treated with piperacillin/tazobactam 3.375 g IV every eight hours and telavancin 750 mg IV daily (6.25 mg per kg). Two doses of telavancin were administered without adverse events or reactions. Patient 3 was discharged on piperacillin/tazobactam 3.375 g IV every eight hours and with instructions to follow up with outpatient wound care.

Further reports evaluating telavancin as an alternative in patients with a vancomycin allergy are needed to confirm a lack of cross reactivity. These three patients had documented vancomycin allergies in their medical records, although skin testing and the detection of antibodies were not reported to confirm a true vancomycin allergy. This case series represents a real world scenario with documented patient allergies encountered at a community teaching hospital.

Poster Title: Use of oritavancin in a patient with a documented vancomycin allergy

Primary Author: Dipal Patel, University of the Sciences, Pennsylvania; **Email:** dpatel1705@mail.usciences.edu

Additional Author (s):
Marina Haroon
Tamara Karcheski
Hien Nguyen
Joseph Reilly

Purpose: Oritavancin is a lipoglycopeptide antibiotic derived from a glycopeptide structure closely related to vancomycin, but with significant differences in pharmacology and activity. Oritavancin is indicated for the treatment of acute bacterial skin and skin structure infections (ABSSSI), and treatment consists of a single 1200 mg intravenous (IV) infusion over 3 hours. The structural similarities between oritavancin and vancomycin may pose a possible risk of cross-sensitivity in patients with a vancomycin allergy. The following case report describes the use of oritavancin for the treatment of cellulitis in a patient with a documented vancomycin allergy. A 31 year old female with a past medical history of intravenous drug abuse (IVDA) was admitted to the emergency department (ED) with a chief complaint of lower right leg pain and swelling that had progressively worsened over four days. Upon arrival, the patient was afebrile and normotensive. She was diagnosed with an ABSSSI on her right leg due to IVDA. At our institution, vancomycin is typically initiated in patients that present with cellulitis who are not considered candidates for oral antibiotic therapy. The patient was not a candidate for vancomycin because she had previously experienced an allergic reaction to vancomycin, which resulted in shortness of breath, hives, and a large bilateral rash on her arms and legs. The infectious disease physician consulted pharmacy and a decision was made to administer oritavancin due to concerns of noncompliance with oral antibiotics and a prior history of cellulitis infections. During the 3-hour infusion, the patient was monitored closely for any hypersensitivity reaction or adverse effects to oritavancin. It was noted that the drug was well tolerated and the patient did not experience any adverse reactions. The patient was subsequently discharged from the ED with a follow-up appointment with an infectious disease physician. Although this vancomycin allergic patient tolerated oritavancin, we did not have

extensive evidence to validate whether this was a true vancomycin allergy. Published data is lacking regarding the cross-sensitivity between oritavancin and vancomycin and this case illustrates a real world scenario with a pragmatic approach where oritavancin was administered successfully and prevented a hospital admission. Further studies are warranted to evaluate the risk of cross-sensitivity between these antibiotics.

Poster Title: Efficacy of default electrolyte selection for initial parenteral nutrition order

Primary Author: Alyssa Marie Cajka, University of the Sciences - Philadelphia College of Pharmacy, Pennsylvania; **Email:** acajka@mail.usciences.edu

Additional Author (s):
Steven Lam
James Hollands
Laura Pontiggia
Angela Bingham

Purpose: Patients receiving default electrolytes in their parenteral nutrition may be at risk for electrolyte abnormalities as they are not receiving individualized amounts, potentially leading to an increase in IV supplementation of individual electrolytes. The purpose of this study is to evaluate the need for boluses of IV electrolytes in patients receiving institution-specific, default electrolytes (Standard: calcium gluconate 9.6 g, magnesium sulfate 10 g, potassium chloride 40 mEq, potassium phosphate 15 mmol, sodium chloride 70 mEq; Renal: calcium gluconate 9.6 g, sodium chloride 20 mEq) as compared to those that did not receive default electrolytes in parenteral nutrition.

Methods: The Institutional Review Board approved this retrospective study. All adult patients admitted to Cooper University Hospital between January 1, 2013 and July 15, 2016 who received parenteral nutrition were included and only their first encounter with parenteral nutrition was recorded. Patients were excluded if they were less than 18 years old, pregnant, had an incomplete medical record, were receiving concomitant enteral nutrition, or experienced refeeding syndrome. Of the 476 patients that were included, 374 received default electrolytes and 102 did not receive default electrolytes. Their electronic medical record was reviewed for sources of IV electrolytes (included potassium chloride, potassium phosphate, magnesium sulfate, sodium phosphate, calcium gluconate and calcium chloride) in addition to their parenteral nutrition during day 1 and day 2 of parenteral nutrition. The primary outcome was the need for IV electrolyte bolus supplementation during day 1 of parenteral nutrition and was analyzed using the chi-square test and logistic regression to control for confounders. The secondary outcomes included need for IV electrolyte bolus supplementation during day 2 and

specific IV electrolyte supplementation required during day 1 and day 2 of parenteral nutrition. The secondary outcomes were analyzed using the chi-square test.

Results: The primary outcome, need for IV electrolyte bolus supplementation during day 1 of parenteral nutrition, was 14 percent greater in patients who received default electrolytes as compared to those that did not receive default electrolytes (56.42 percent vs. 42.16 percent, relative risk 1.34, P equals 0.0105). After a multivariate analysis of effect of default electrolyte order on requirement of IV electrolyte supplementation controlling for confounders, the difference between the two groups was still found to be significant (odds ratio 1.776, 95 percent confidence interval, 1.141 to 2.766, P equals 0.0110). The secondary endpoints of need for potassium chloride during day 1 (30.21 percent vs. 17.65 percent, P equals 0.0118) and need for sodium phosphate supplementation during day 2 (15.51 percent vs. 7.84 percent, P equals 0.0471) were also significant.

Conclusion: Ordering our institution-specific, default electrolytes in parenteral nutrition results in a greater need for IV electrolyte supplementation. The current default provision of potassium and phosphorous at our institution may be reconsidered due to the significant increase in IV supplementation required for these electrolytes.

Poster Title: Treatment of urinary tract infections in a community hospital pediatric emergency department

Primary Author: Cristen Whittaker, University of the Sciences in Philadelphia, Pennsylvania; **Email:** cwhittaker@mail.usciences.edu

Additional Author (s):
Susanna Price
A. Maggie Randazzo
Diana Solomon

Purpose: Urinary tract infections (UTIs) are one of the most common infections that occur in the pediatric population. In recent years, antibiotic resistance has been increasing resulting in pediatric UTIs that are more difficult to treat. The purpose of this study was to establish the foundation for a pediatric antimicrobial stewardship program via retrospective analysis of UTI treatment at a community hospital. Implementation of such a program will result in prevention of unnecessary antibiotics, ensure appropriate drug selection and dosing, and improve patient outcomes.

Methods: After gaining approval from the IRB, a retrospective chart review of all pediatric patients diagnosed with a urinary tract infection (UTI) in the previous year was performed. The appropriateness of the dose and choice of initial and discharge antibiotics was analyzed for each case. The primary reference used for determining appropriateness of the dose and spectrum of coverage was the Harriet Lane Handbook. Upon the return of cultures at day three, the continued appropriateness of discharge antibiotics was assessed. It was also recorded if a change in discharge antibiotics was made based on the availability of cultures and susceptibilities.

Results: In one year, 51 patients were treated for UTI at this community hospital. According to the Harriet Lane Handbook, 55 percent of patients received appropriate antibiotics based on the dosage or coverage of typical causative organisms. Only 36 percent of patients received appropriate antibiotics upon discharge. At the time of evaluation, 45 (88 percent) patients had a urine culture performed and out of the 45 patients who were given one, 57 percent had

positive cultures by day three. Out of 26 patients with positive urine cultures, 6 (23 percent) were now considered to be taking inappropriate antibiotics and only 4 of those patients were switched to a medication that the cultured organism was susceptible to. Out of 19 patients that had negative urine culture results at day three, zero patients had documentation of a call to the family members telling them that they no longer need to continue taking the full course of antibiotics they were originally prescribed. Additionally, nearly half of all orders (47 percent) were automatically verified by the computer system as compared to being verified by a pharmacist prior to dispensing.

Conclusion: The results of this study indicate the necessity of an antimicrobial stewardship program for the pediatric population. The authors propose several recommendations to establish the foundation of antimicrobial stewardship practices. The first recommendation is to remove computer automated verification of antimicrobials. A urine culture at presentation should be standardized for all suspected UTIs. When cultures are finalized the pharmacist should call the patient's family, adjust antibiotics accordingly, and document the intervention. Similarly, if cultures return negative, the family should be contacted and antibiotics discontinued. Implementation of these recommendations provides the beginning of pediatric antimicrobial stewardship practices at this institution.

Poster Title: Determination of the clinical impact of a dedicated transplant pharmacy service

Primary Author: Maria Heaney, University of the Sciences in Philadelphia, Pennsylvania; **Email:** mheaney@mail.usciences.edu

Additional Author (s):
Elora Hilmas
Bethany Sharpless
John Giamalis

Purpose: We hope to determine the impact on patient safety, continuity of care, and inpatient workload for a dedicated transplant service compared to baseline for inpatient service. In addition, we want to determine the value of a pharmacist in a transplant clinic.

Methods: Baseline includes data from one donor and recipient pair managed by the fragmented service. The following month, a dedicated pharmacy service was implemented when a pharmacy student was on solid organ transplant rotation. During this time, we collected data from two donor and recipient pairs and one recipient from a cadaveric donor. Patient safety was compared using pharmacy intervention documentation and the associated patient outcomes that were recorded in the baseline period versus the dedicated service period. We also compared cost savings from pharmacy interventions. For inpatient workload, we compared the time used for transplant patient care activities, including rounding, counseling, and documentation in the medical record, as well as the number of notes written. Additionally, a satisfaction survey was distributed to transplant providers managing all of our study patients to quantify the value of the transplant pharmacy service. For outpatient service, we characterized the number, type of interventions, and patient encounters accomplished by the pharmacy resident who attended clinic.

Results: A dedicated service resulted in a greater mean number of interventions (8 per recipient in baseline vs. 13.7 per recipient in the dedicated service period) and greater cost savings (468 dollars vs. 1212 dollars per recipient). In addition, there was greater time spent on rounds per patient with the medical team (60 minutes vs. 80 minutes (averaged for recipients)) and a greater number of progress notes written (3 vs. 4.7 (averaged for recipients)). For the

total time spent writing progress notes, it was similar in comparison between the two periods, despite more notes being written during the dedicated service period. Of the two responses to the provider satisfaction survey, both indicated that they were very satisfied with the dedicated service compared to the current fragmented service, and they would prefer to have a dedicated service. They indicated that their interactions with pharmacy, prescribing support, and patient safety improved with daily involvement in patient care. Finally, the providers indicated that pharmacy plays an important role in discharge counseling and that daily involvement of pharmacy in patient care is associated with a cost-benefit. In the outpatient clinic, the pharmacist saw 46 patients and made 362 interventions over 11 weeks.

Conclusion: A dedicated service allowed for daily participation in team rounds and more daily progress notes compared to baseline services. There appears to be a significant improvement in the number of interventions along with greater cost saving. The dedicated service wrote a greater number of notes in the same average total time per recipient, possibly as a result of becoming more familiar with each case with daily involvement. Prescribers provided positive feedback about their experience with a dedicated service. Finally, there is also great opportunity in the outpatient clinic environment for pharmacists to provide improved medication management for transplant patients.

Poster Title: Antiretroviral Use Evaluation at a Tertiary Care Academic Medical Center

Primary Author: Aisha Uddin, University of the Sciences in Philadelphia, Pennsylvania; **Email:** auddin@mail.usciences.edu

Additional Author (s):
Jennifer Welch
Wai-Ying Lam

Purpose: In 2015, the list of recommended, alternative, and other initial combination antiretroviral (ARV) regimens for treatment-naïve patients was updated in the HIV/AIDS guidelines in accordance to available data. Recommended first line options include four integrase inhibitor based-regimens and one protease inhibitor (PI) based-regimen. Alternative and other regimens are considered to have clinical disadvantages associated with them compared to the recommended regimens, but may be preferred for some patients. At UTMB Health, we sought to update and streamline our ARV formulary to reflect current HIV/AIDS treatment practices

Methods: A retrospective usage review of all ARV strengths and dosage forms on formulary was conducted with utilization data from October to December 2015. Patient demographics, HIV-related clinical characteristics, and medications comprising the HIV regimen were collected and assessed. ARVs were recommended to be removed from formulary if the medication had no usage or minimal usage. An additional usage analysis from July to September 2015 was conducted on agents that were recommended to be removed due to minimal usage. Findings and recommendations were presented at the UTMB Health's August 2016 Antimicrobial Advisory Subcommittee meeting.

Results: Of 91 patients included in the evaluation, 48.3 percent of patients were on a recommended regimen, while 27.4 percent of patients were on an alternative or other regimen. In addition, 24.1 percent of patients were on a regimen that is no longer endorsed by the HIV/AIDS guidelines. We recommended the removal of atazanavir 100 mg, 150 mg, and 200 mg capsules, darunavir 400 mg tablet, indinavir, nelfinavir, saquinavir, tipranavir, didanosine, stavudine, zidovudine capsule, delavirdine, efavirenz 50 mg and 200 mg capsules, and abacavir-

lamivudine-zidovudine combination tablet due to no usage. We recommended the removal of maraviroc 300 mg tablet, fosamprenavir, lopinavir-ritonavir oral solution, ritonavir oral solution, nevirapine oral suspension, and emtricitabine capsules due to minimal usage. Based on the medication use evaluation, the Antimicrobial Advisory Subcommittee approved the removal of all non-usage products and all except for three minimal usage agents from the formulary based on our recommendations. The three minimal use products that were kept on formulary included lopinavir-ritonavir oral solution for pediatric patients, nevirapine oral suspension for prevention of maternal-fetal transmission of HIV, and emtricitabine capsules since only single agents are allowed to be administered to the prison patient population.

Conclusion: All of our recommendations for removal from formulary were approved with the exception of three dosage forms due to use in specific patient populations. A total of 29 ARV dosage forms were removed from the formulary.

Poster Title: Customized electronic parenteral nutrition prescribing reduces overfeeding and better meets patient protein needs

Primary Author: Rory Moran, University of the Sciences in Philadelphia, Pennsylvania; **Email:** rmoran@mail.usciences.edu

Additional Author (s):
MaKindree Nicolosi
Christine Roussel
Ariel Orland

Purpose: When optimized, parenteral nutrition is administered with the goal of improving the clinical course and outcome in appropriate patients; but maybe also cause or exacerbate metabolic complications and organ function. Our subjective clinical experience was that patients receiving parenteral nutrition in our facility were overfed without meeting their protein needs; which puts our patients at risk for metabolic complications without helping them meet their goals. The purpose of our intervention was to institute a new process for prescribing parenteral nutrition utilizing the electronic prescribing system to provide customized calculations in an attempt to optimize patient's protein and non-protein calorie needs.

Methods: The institutional review board approved this observational study, assessing the impact of a clinical quality project aimed at improving the safety and efficacy of the parenteral nutrition prescribed within a 250 bed community hospital by altering the prescribing process. Prior to March 2016 prescribers utilized a paper form containing two standards (central and peripheral) and a customized solution option. The paper form only allowed for prescribers to enter the total volume, percent dextrose and amino acids in the final solution, and volume and percent of lipids. The concern was that lack of patient specific calculations lead to inappropriately high doses of carbohydrates and lipids, and sub-optimal dosing of amino acids. The new electronic process created a customized algorithm where prescribers determined all macronutrients based on grams/kilogram/day or kilocalorie/kilogram/day with recommendations based on clinical stress levels; then the computer system did the math based on a specific patient weight. A total of 60 inpatients, requiring parenteral nutrition via central

access during a six month period were assessed for four endpoints based on the initial order. Patient cohorts were divided into those prescribed parenteral nutrition using the paper form, compared to those prescribed after the customized, weight-based electronic process was implemented. The endpoints evaluated were total kilocalories/kilogram/day, percent and magnitude of actual macronutrients compared to the recommended weight based macronutrients.

Results: When prescribers order macronutrients by specifying the final solution concentration and the total volume, patients infrequently received macronutrients within 15 percent of the recommended amount. In the paper form group (30 patients), the initial order was within 15 percent of goal only 23, 23, and 27 percent of the time for dextrose, lipids and amino acids, respectively. For patients in the electronic prescribing cohort (30 patients), prescribers hit weight based recommendations 100 percent of the time for all macronutrients, as the prescribing is weight based. Patients were over fed dextrose on the initial day of parenteral nutrition 60 percent of the time, with 37 percent receiving 65 percent or more than recommended. Thirteen percent of patients received more than double recommended daily dextrose load on the first day of therapy. Sixty percent of patients were overfed lipids, with 10 percent between double and triple the recommended daily amount in the initial bag. Protein needs were more than 15 percent less than goal in over 50 percent of patients treated by a prescriber being limited to entering a final solution amino acid concentration.

Conclusion: The goal of this clinical quality improvement process was to optimize safety and outcomes in patients receiving parenteral nutrition through customized, weight based dosing of macronutrients. Overfeeding was reduced for lipid and carbohydrates, which should translate to less hyperglycemia. Protein requirements were better optimized which should translate to improved healing, but assessing this was outside the scope of this study. The clinical effects of parenteral nutrition must be evaluated in larger, randomized controlled trials due to the site specific variability in indications and manner for which parenteral nutrition is prescribed.

Poster Title: Evaluation of aminoglycoside therapy at an academic medical center

Primary Author: Jessica Sylvester, University of the Sciences in Philadelphia, Pennsylvania;
Email: jsylvester@mail.usciences.edu

Additional Author (s):
Lauren Marie Atkinson
Jonathan Burns
Ethan Englert

Purpose: The aminoglycosides are a class of bactericidal antibiotics that are active against aerobic, gram-negative bacteria and commonly used in hospitalized patients. There are several considerations that must be made when using aminoglycosides, including dosing strategy and monitoring parameters. They can be administered once, twice, or thrice daily and recommended doses and target serum levels differ depending on indication and dosing strategy. Additionally, while gentamicin and tobramycin are usually dosed the same, amikacin has unique dosing. The purpose of this drug use evaluation is to characterize aminoglycoside use at the Hospital of the University of Pennsylvania (HUP).

Methods: This pilot for a formal drug use evaluation examined seven patients who were ordered and received at least one dose of an aminoglycoside at the HUP from January 1st to December 31st 2015. The following variables were recorded and then compared to the recommended values from hospital guidelines: dosing strategy, dose in total milligrams, milligram per kilogram dosing, evaluation of renal function and renal adjustment if warranted, as well as any serum levels. Additional variables recorded included specific drug used, indication, and duration of therapy in number of doses. The principal questions that we sought to answer were: did initial and subsequent doses meet internal guidelines and did peak and trough concentrations meet internal goals? This evaluation was determined to be quality improvement by the University of Pennsylvania's Institutional Review Board.

Results: In this pilot investigation, seven patients who received extended interval were evaluated of which 50% were male, with a mean age of 52 + 6 years, median weight of 86 kg (range 48 – 164), and a mean creatinine clearance of 90 mL/min + 11. Of those receiving

extended interval, indication was varied as was location with three patients in the medical intensive care unit, three on oncology floors and one in the neurology step down during time of administration. All but one patient received amikacin with a mean dose of 15mg/kg +1.74 on adjusted body weight. The other patient received tobramycin at a dose of 5mg/kg on adjusted body weight. Appropriate peak level timing was completed in one patient. Random levels were obtained in all but one patient and four patients had two levels drawn.

Conclusion: Per institutional guidelines, use of an extended interval dosing strategy was appropriate in all patients based on renal function. The attainment of peak levels was suboptimal, however multiple random levels were frequently obtained allowing the determination of patient specific kinetics and optimization of dosing. Appropriate timing of aminoglycoside peaks would allow for more accurate interpretation of patient pharmacokinetics data by pharmacists and should be improved.

Poster Title: Antimicrobial stewardship on a rural health medical mission trip in Jamaica

Primary Author: Micaela Genca, University of the Sciences in Philadelphia, Pennsylvania; **Email:** mgenca@mail.usciences.edu

Additional Author (s):
Lauren Atkinson
Thaddeus McGiness
Yvonne Phan
Jessica Adams

Purpose: Antimicrobial stewardship is a coordinated global approach to promote the proper use of antimicrobial medications utilizing the appropriate agent, dosing, and duration of therapy for the pertinent indication. The goal of this approach is to improve patient outcomes and prevent the spread and development of drug-resistant microorganisms. The purpose of this study was to evaluate the antimicrobial stewardship interventions that were made by a pharmacy team consisting of pharmacists and P4 Advanced Pharmacy Practice Experience (APPE) students on a rural health medical mission trip to Jamaica in June 2016.

Methods: A retrospective analysis of all pharmacy interventions for antimicrobial orders during a 10-day medical mission was performed. The pharmacy team was required to document interventions made on the back of each prescription. Age, gender, number of antimicrobial prescriptions, and the indications were recorded. The prescriptions were divided into the types of antimicrobial prescribed: antibiotic, antiparasitic, or antifungal and whether the order was written by medical or dental. Interventions were assigned to one of 12 categories: Medication change due to preferred therapeutic alternative, allergy, non-formulary agent, non-formulary dosage form, or out of stock agent, change in strength, frequency, duration of therapy, or route of administration, medication added or deleted, or disease specific recommendation. Disease-specific recommendations were when the pharmacy member recommended an antimicrobial based upon the diagnosis provided by the medical team. Whether the intervention was made by a pharmacist or student was also recorded. The study was given exempt status by the IRB at the University of the Sciences in Philadelphia. Descriptive statistics were performed. The primary endpoint was the percentage of all antimicrobial prescriptions that required pharmacy

intervention. Secondary endpoints included rates of each type of intervention, percentage of interventions on antimicrobials filled for medical compared to dental patients, percentage of interventions made by pharmacy students versus pharmacists, and the median number of interventions per individual antimicrobial prescription.

Results: Of the patients requiring antimicrobial prescriptions, 74.5% were female. The median (interquartile range IQR) age was 39 years (22-52). There were 325 (92.0%) and 28 (8.0%) prescriptions written by the medical and dental team, respectively. Of the antimicrobial prescriptions,189 (53.9%) of 353 required 241 interventions by pharmacy. A mean (standard deviation SD) of 0.68 (+ 0.76) interventions were made per prescription. Of 189 interventions, 180 (95.2%) were accepted by attending physicians or dentists. Of those antimicrobial prescriptions, 175 (49.9%) were antibacterial agents, 165 (47.6%) were antifungal agents, and 9 (2.6%) were antiparasitics. Pharmacy interventions included 44 (18.3%) medication changes due to non-formulary dosage form, 41 (17.0%) changes in the duration of therapy, 41 (17.0%) changes in the frequency of administration, 37 (15.4%) disease-specific recommendation, 28 (11.6%) dosage strength changes, 19 (7.88%), therapeutic alternative recommendations, 16 (6.6%) non-formulary medication changes, 11 (4.6%) interventions involved new medication addition, 2 (0.8%) out of stock changes, and 2 (0.8%) route of administration changes. Of the 241 antimicrobial interventions, 151 (62.7%) interventions were made by students and 47 (19.5%) interventions were made by pharmacists.

Conclusion: Antimicrobial stewardship provided by the pharmacy team resulted in medication optimization for suspected infections with the intention of aiding the global effort to reduce antimicrobial resistance rates. Due to a restricted formulary, consisting of primarily oral agents, many interventions were formulary management decisions. Given the rural health setting, we were unable to draw cultures, test sensitivies to antibiotics, and lacked the diagnostics to confirm infections; therefore, the pharmacy interventions made were crucial to antimicrobial stewardship during this medical mission trip.

Poster Title: Evaluation of vancomycin dosing strategies in elderly patients

Primary Author: Taylor Jones, University of the Sciences in Philadelphia

Philadelphia College of Pharmacy, Pennsylvania; **Email:** tjones1652@mail.usciences.edu

Additional Author (s):
James Hollands
Krystal Hunter
Laura Siemianowski
Angela Bingham

Purpose: Vancomycin is largely considered the drug of choice in treating infections caused by methicillin-resistant Staphylococcus aureus. The optimal dosing and monitoring methods are still yet to be determined, especially in the elderly patient population where several pharmacokinetic parameters change. The primary objective of this study is to compare the weight-based dosing strategies of intravenous (IV) vancomycin used to achieve target serum trough concentrations between non-elderly and elderly patients (greater than 65 years old). Secondary objectives will include the incidence and associated outcomes of supratherapeutic IV vancomycin dosing.

Methods: The Institutional Review Board approved this single center, retrospective study using a pre-existing vancomycin dosing database. Adult patients initiated on vancomycin during hospitalization from January 1, 2009 through December 31, 2015 at Cooper University Hospital were included. Patients were at least 18 years of age and received a scheduled regimen of IV vancomycin for at least 36 hours and at least one interpretable vancomycin serum trough concentration. Patients on a scheduled regimen of IV vancomycin for less than 36 hours with a supratherapeutic vancomycin serum trough concentration were also included. Vancomycin serum trough concentrations between 15-20 mg/L were considered therapeutic; concentrations less than 15 mg/L were considered subtherapeutic and concentrations greater than 20 mg/L were supratherapeutic. An interpretable vancomycin serum trough concentration is defined as a serum level drawn within 2 hours of the next scheduled dose. Nephrotoxicity is defined as a 0.5mg/dL increase for 2 days or 50 percent increase from the serum creatinine baseline. Patients were categorized into 2 groups based on age: non-elderly (age less than 65

years) and elderly (age greater than or equal to 65 years). A subgroup analysis, defined a priori, compared the elderly demographic of ages 65-74 years, 75-84 years, and greater than 85 years.

Results: Of the 561 patients included that met inclusion criteria, 201 were elderly (65-74 years (n equals 105); 75-84 years (n equals 57); greater than 85 years (n equals 39)). Loading doses were administered in 46.3 percent of the elderly and 29.7 percent of the non-elderly patients (P less than 0.001). The initial mean maintenance dose administered in the elderly was 23.4mg/kg/day compared to 32.35mg/kg/day in the non-elderly (P less than 0.001). Initial maintenance dose frequency for the elderly was either every 24 hours (64.04 percent) or every 12 hours (35.96 percent). The non-elderly maintenance dose frequency also included every 24 hours (7.5 percent), every 12 hours (90.5 percent), and every 8 hours (2 percent). Mean initial trough concentrations were therapeutic at 15.235mg/L and 15.010mg/L in the elderly and non-elderly, respectively (P equals 0.757). Supratherapeutic levels were drawn in 37.3 percent of elderly compared to 35.4 percent in non-elderly (P equals 0.647). Concomitant nephrotoxic agents were used in 20.4 percent of the elderly patients compared to 67.5 percent of non-elderly (P equals 0.002). Nephrotoxicity was not significantly different in the elderly and non-elderly population (9 percent vs. 11.7 percent, P equals 0.319).

Conclusion: Vancomycin dosing in elderly patients and subsequent achievement of an initial therapeutic trough concentration require consideration of patient-specific factors. This includes, but not limited to age, drug indication, concomitant nephrotoxins, and other comorbid conditions. Elderly patients require less total daily drug to achieve the same initial trough concentrations seen in non-elderly patients. Furthermore, despite similar initial trough concentrations, the incidences of nephrotoxicity and supratherapeutic concentrations did not significantly differ despite less frequent use of concomitant nephrotoxins in the elderly.

Poster Title: Evaluation of appropriateness and prescribing patterns of daptomycin use in methicillin resistant staphylococcus aureus (MRSA) infections in three community hospitals

Primary Author: Samantha Phillips, University of the Sciences in Philadelphia

Philadelphia College of Pharmacy, Pennsylvania; **Email:** sphillips@mail.usciences.edu

Additional Author (s):
Sai Kundur
Nikunj Vyas
Tanvi Patel

Purpose: Infections due to multi-drug resistant organisms are gradually increasing. One of the most challenging gram-positive organisms concerning nosocomial infections includes MRSA. In an effort to better understand institutional use of daptomycin, the primary objective of this study was to evaluate the appropriateness and prescribing patterns of daptomycin usage in MRSA infections. A subgroup evaluation was to determine the safety and efficacy of daptomycin dosing in obese and morbidly obese patients. The secondary objective was to measure the institution's rates of resistance of MRSA and vancomycin minimum inhibitory concentration (MIC) trends.

Methods: An institutional review board approved retrospective chart review was performed on patients receiving daptomycin therapy between January to June 2016. Inclusion criteria were patients with age greater than or equal to 18 years who received at least one dose of daptomycin for documented MRSA infections. Patients were excluded if they were immunocompromised, pregnant or had previous exposure to daptomycin. Appropriateness was defined based on adherence to institutional protocol for prescribing daptomycin along with indication, dose, length of therapy (LOT) and rationale for daptomycin use. For subgroup analysis, patients were characterized as obese if body mass index (BMI) was 30 kilograms per square meter or greater, and morbidly obese if BMI was 40 kilograms per square meter or greater. Local resistance patterns were analyzed for MRSA and variations in MIC for vancomycin, daptomycin, and linezolid were reported.

Results: This study included 75 patients who received daptomycin therapy. Median age was 53.5 (24-99) years with 48.6 percent females. Most common indications were skin and soft tissue infection (SSTi) (26.6 percent), osteomyelitis (20 percent), and endocarditis (13.3 percent). Bacteremia was observed in 48 percent of patients. Daptomycin was appropriately prescribed in 84 percent of patients. Most common reasons for daptomycin were MRSA bacteremia with vancomycin MIC greater than 1 (29.3 percent) and vancomycin allergy (25.3 percent). Median length of stay was 8 (2-52) days and median LOT was 7 (2-47) days. Sixty one percent of patients received doses at 6mg/kg compared to 13.3 percent and 10.7 percent who were dosed at 8 and 10 mg/kg respectively. All patients were dosed by actual body weight. Fifteen percent of patients were obese and 29.3 percent of patients were morbidly obese, and of these daptomycin was appropriately indicated in 70 percent of patients with most common reason for use being vancomycin failure. In 2016, we observed 1018 isolates of MRSA with 4.8 percent having vancomycin MIC greater than 1, and with 1.3 percent expressing vancomycin MIC of 2. However, overall daptomycin use was higher in 2016 compared to 2015 (6.68 vs. 4.88 DOT/1000PD).

Conclusion: In managing MRSA infections, daptomycin use is highly appropriate at our institution. The most common reason for use was elevated vancomycin MIC, and the most common indication was SSTi. Vancomycin kinetics remain a challenge in obese population leading to increased daptomycin usage. Rates of elevated vancomycin MICs remain low at our institution; however, the overall usage of daptomycin is on the rise.

Submission Type: Evaluative Study

Session-Board Number: 2-303

Poster Title: Medication list discrepancies discovered during medication reconciliation in an outpatient family medicine clinic

Primary Author: Kyle Hultz, University of the Sciences Philadelphia College of Pharmacy, Pennsylvania; **Email:** khultz@mail.usciences.edu

Purpose: The purpose of this study was to determine the amount and type of discrepancies discovered during medication reconciliation by a pharmacy student. The study also analyzed the amount of time it took to reconcile and document the entire process. In doing so, the medication reconciliation process could be streamlined, thus, increasing the pharmacist's ability to expand the role of pharmacy in the family medicine clinic.

Methods: The pharmacy student initiated all home medication interviews by collecting demographics for each patient either verbally or through the electronic medical record. This information was vital in identifying the clinic's specific patient group and allowed the process to be tailored accordingly. Before entering the room, the student accessed the electronic medical record and assessed the current medication list to identify duplications, inaccurate doses, gaps in therapy, and whether refills might be needed. Then, the student conducted individual medication reconciliation interviews. These sessions were held in private patient rooms, which not only allowed for accurate medication reconciliation, but also provided a chance for any medication questions to be answered and prescription counseling opportunities to be taken advantage of. Once the interview was complete, interventions were documented in an Excel spreadsheet along with the patient's demographic information. This spreadsheet was also used to run statistical analyses at the conclusion of the study. Concerns about the patient's current medication list, adherence, and any other problems were reported to the medical residents and attending preceptors.

Results: Patients enrolled into the study were 18 years of age or older and must be patients within the St. Joseph medical group. Patients who did not have any home medications were excluded from the study. Data was collected over a 3-week period at one site in downtown Reading, PA. 43 patients were enrolled into the study and medication reconciliations were completed. The average time that it took to complete each interview, document the interventions, and report discrepancies to the appropriate provider was 8.7 minutes. A majority

of the patients were female (62.7%) and 48.8% were of Hispanic ethnicity. The average age was 47 years old and the average number of home medications was 8.36. Detailed medication list reviews revealed 161 discrepancies when compared to the electronic medical record. These discrepancies were distributed amongst missing medications (49), extra medications (44), duplicate (18), improper frequencies (22), and inaccurate doses (28). A total of 10 patients were determined to be non-adherent. Medication-specific counseling was provided to these patients during the interview, and the importance of adherence to their medications was reinforced.

Conclusion: Pharmacy involvement in the medication reconciliation process may lead to better patient outcomes and improved patient care. Discrepancies were resolved with the resident physicians and correctly updated in the EMR. A need was identified for a permanent pharmacy presence at the clinic, which has led to the development of a business case for an ambulatory care pharmacist. In addition to performing medication reconciliations, this pharmacist will help integrate the outpatient clinic and on-site retail pharmacy, make recommendations to providers, and counsel patients as necessary in order to provide direct patient care and generate revenue for the health system.

Poster Title: Outcome measures for pharmacy anticoagulation monitoring program

Primary Author: Austyn Grim, University of the Sciences Philadelphia College of Pharmacy, Pennsylvania; **Email:** agrim@mail.usciences.edu

Additional Author (s):
Elora Hilmas

Purpose: The Joint Commission established a National Patient Safety Goal (NPSG) that identified anticoagulants as a medication class that requires routine monitoring. Upon initial conception, our institution's anticoagulation monitoring program aimed at improving anticoagulation efficacy and safety through the interdisciplinary implementation of best practice guidelines, specialized ordersets, and an official anticoagulation policy. For the last eight years, our pharmacy department has participated in the program utilizing computerized monitoring, protocols, and pharmacist-directed surveillance. Using pharmacy intervention data and monthly reports, the purpose of this study was to determine the patient safety outcomes and cost savings of pharmacy monitoring in 2015.

Methods: Monitoring initiated originally for our three formulary anticoagulants (enoxaparin, heparin, and warfarin). Over time, the list of anticoagulants has grown and now pharmacists monitor all anticoagulant therapy, even if the agent is non-formulary. Pharmacists were directed to follow patients on anticoagulation treatment dosing, long-term prophylaxis, and short-term prophylaxis lasting greater than seven days. Pharmacists are provided with a dynamic list of patients on anticoagulation in our medication ordering software (Epic, Verona WI) and a home-grown web-based program to document monitoring. Daily, the pharmacists document the patients' efficacy and toxicity outcomes within this program. Recommendations to improve a patient's therapy are made by the pharmacist directly to the prescribing provider. Utilizing Epic, pharmacists document all anticoagulation interventions. The pharmacists' intervention documentation includes the specific anticoagulant, type of intervention, time spent generating the intervention, acceptance by the interdisciplinary team, description of the intervention, and the patient's clinical situation surrounding the documented intervention. Based on the type of intervention, an outcome is associated along with a cost savings amount determined by literature standards.

Results: Ninety-nine percent of patients who met criteria were followed by pharmacy with a total of 160 patients and 186 orders. Ninety-six percent of the initial anticoagulant doses were found to be appropriate with an orderset being utilized for 72 percent of those initial doses. Ninety-three percent of the 211 pharmacist interventions were accepted by the multidisciplinary team when applicable. Fifty-five (26 percent) of the 211 pharmacist interventions prevented an anticoagulant adverse drug reaction, toxicity, or medication error with the most common interventions including bridging recommendations, inappropriate doses, inappropriately drawn anti-Xa levels, and need for anti-Xa levels. Of the 55 pharmacist interventions that prevented an anticoagulant adverse drug reaction, toxicity, or medication error, 34 (85 percent) involved enoxaparin, 5 (13 percent) involved heparin, and 1 (2 percent) involved warfarin. Of the 211 total pharmacist interventions, 105 enhanced therapeutic effect of the anticoagulant, 44 prevented toxicity, 30 involved order clarification, 17 involved policy compliance, 11 prevented a medication error, and 4 provided cost savings. Throughout the 2015 year, 18,209 dollars of cost savings has been provided by our anticoagulation monitoring program.

Conclusion: We have identified that pharmacists can ensure that initial anticoagulant doses as well as dosage adjustments are safe and warranted based on drug levels. Documented pharmacist interventions and outcomes data have provided us with the information we need to refine our anticoagulation ordersets and policies, promoting exemplary patient safety. By developing a standard of anticoagulation practice which includes pharmacy monitoring, our institution has succeeded in decreasing the number of adverse drug events, toxicities, and mediation errors associated with anticoagulant use. Finally, we were able to establish cost-savings as an additional benefit to our anticoagulation monitoring program implementation.

Poster Title: Integration of pharmacy students into an interprofessional education model in a patient-centered medical home

Primary Author: Anisha Shah, University of the Sciences, Philadelphia College of Pharmacy, Pennsylvania; **Email:** ashah1736@mail.usciences.edu

Additional Author (s):
Jennifer Fiebert

Purpose: Ambulatory care is increasingly being provided in a patient centered, team based system. In order to provide effective team-based care, interprofessional education is necessary to train future providers. Interprofessional education occurs when students from two or more professions learn about, from, and with each other to enable effective collaboration and improve health outcomes.[1] Pharmacy students benefit from this learning method as it prepares them to enter their careers as valued members of the collaborative practice team.
The purpose of this initiative was to expand interprofessional education in a patient-centered medical home to include pharmacy students.

Methods: Students were incorporated into the existing physician-centric learning model first by becoming active participants in the team huddle that occurs prior to the clinic session. During the huddle, all upcoming patients are discussed which includes reviewing clinical information and triaging anticipated needs (ie: education, laboratory tests or procedures and pharmacotherapy needs) with all members of the team. The pharmacy student added valuable input during the huddle, using this time to provide information about optimizing pharmacotherapy and patient education opportunities while also determining which patient visits should be targeted.
The pharmacy student then participated in the identified patient appointments, during which the medical student and/or resident would perform the history and physical and work with the pharmacy student to determine the assessment and plan. Finally, the pharmacy student and the medical resident presented the case together to the family medicine attending and/or pharmacy attending. The student then provided counseling and addressed any medication therapy issues identified. This model served to enhance the education of the medical students

and residents by having them work collaboratively with a pharmacy student, gaining a deeper insight into appropriate pharmacotherapy, compliance and monitoring parameters. Working together with the medical students and residents allowed the pharmacy student to gain a deeper understanding of physical assessments and social needs and set the framework for effective teamwork in the provision of primary care.

Results: Pharmacy students became more engaged when they were actively involved in all aspects of the patient's appointment. Communication skills and collaboration among all team members increased with the addition of a pharmacy student into the learning model. Medical students and residents as well as pharmacy students reported that better patient care was provided with the integration of the pharmacy student into the learning model.

The biggest challenge identified during the first weeks incorporating a pharmacy student into the learning model was reservation from some of the first year medical residents (who were not as accustomed to working with a pharmacist), which created a passive environment for the student. Engaging the medicine attending to allow the pharmacy student to take on an active role in the patient visit (ie: by having the student present the case to the medical attending directly) helped create a more collaborative and inclusive learning environment for the pharmacy students in a trickle-down fashion. In addition, having the medical residents present the case directly to the pharmacy preceptor (who served as an "attending pharmacist" to the residents) allowed for the residents to establish a relationship of trust with a pharmacist, necessitating relying on their expertise.

Conclusion: Creating an interprofessional learning environment where pharmacy students train directly with all members of the team enhances the education of both pharmacy and medical students and residents. It also provides the opportunity to practice collaborative care by working together towards a common goal. Ultimately, this model not only engages all different disciplines, but also ensures that patients are able to have better quality of care that is specific to each individual. This is important in contributing to the ability of students to participate in an effective team-based patient-centered model of care in the future.

Stacy Dalpoas

Purpose: Inpatients in The Johns Hopkins Hospital (JHH) relocate between nursing units during the hospital stay for changing healthcare needs. A nurse is responsible for directing patient-specific medications to receiving units during patient transfers. However, additional insulin pens are dispensed for patients upon arrival to new units due to an absence of medication transfer, resulting in excessive patient charges and pharmacy costs. Preliminary data indicated new pens dispensed on 35% of transfers. The JHH Department of Pharmacy implemented a pilot of medication transfer bags inserted in patient charts for easier transfer of medications with patients to avert unnecessary dispensing.

Methods: Clinical Customer Service Representatives (CCSR) inserted 3-hole punched medication transfer bags in patient charts on three inpatient nursing units serving the neurosciences population at different levels of care (Neurosciences Critical Care Unit and associated step-down units). Prior to the patient leaving the sending unit, a checklist item in the Patient Flow worksheet prompted nursing to place patient-specific medications in the bag. The intervention was implemented on November 2015 and the process change and use of the medication transfer bag was reviewed with the nurses and pharmacists. Pharmacists were educated to not dispense pens secondary to transfer orders unless pens were requested by a nurse. Information on dispensed insulin pens was gathered from triggered charges within the pharmacy system and reviewed across visit movement between the three units. The dispensing and patient charges on transfer were analyzed for the time period prior to (June to December 2014) and after (January to March 2016) the implementation of the medication transfer bags to evaluate for changes in insulin pen dispensing patterns.

Results: Pre-intervention data collected in 2014 indicated that amongst transfers between the Neurosciences Critical Care Unit and the associated step-down units, 47 new insulin pens were dispensed within twelve hours of patient transfer to a new unit out of 136 total transfers. This indicated that new insulin pens were dispensed on 35% of total patient transfers, which represented 41% of the 100 patients analyzed in 2014. After implementation of the medication transfer bag pilot on these units, 35 new insulin pens were dispensed within 12 hours of transfer out of 126 total transfers. This represented 28% of the total patient transfers and 37% of the 94 patients evaluated in 2016.

Conclusion: Trends seen from pre-intervention data in 2014 indicated a significant number of patient transfers between the NCCU and associated units that resulted in new insulin pens dispensed within 12 hours of transfer. Due to the unlikely necessity of multiple insulin pens in this patient population, patients transferring between these units have been inappropriately dispensed multiple pens throughout their stay. Data from the medication transfer bag pilot indicate a method for reducing unnecessary dispensing of insulin pens, and potentially other patient specific medications, for patients during movements throughout the hospital stay. Additional cost savings analysis for the intervention is underway.

Poster Title: Shared decision making and anticoagulation: Results of a patient survey

Primary Author: Troy Lewis, Wilkes University, Pennsylvania; **Email:** troy.lewis@wilkes.edu

Additional Author (s):
Dominick Trombetta

Purpose: The introduction of new oral anticoagulants (NOACs) has been practice changing in thromboembolism treatment and prevention in nonvalvular atrial fibrillation. Despite potential patient-oriented advantages, emerging practice observations suggest that patients are still less likely to choose NOACs over traditional warfarin therapy. These emerging therapies present an opportunity for health-care providers to engage patients in shared-decision making discussions. A lack of education and patient-provider discussion decreases the likelihood of making clinical decisions that incorporate patients' individual needs and concerns. The purpose of this study is to evaluate the education patients received regarding safety, efficacy, and cost prior to initiating anticoagulation therapy.

Methods: A questionnaire containing nine elements was developed, and eligible patients were surveyed after informed consent was obtained. The questions addressed patient knowledge of choice alternatives, costs, safety, and efficacy in their current anticoagulation therapy. Survey items were scored on a five-point Likert scale from strongly disagree to strongly agree. Patients completed surveys from April to September 2016. Patients who received oral anticoagulation therapy were identified by the department of pharmacy services at Allied Services Rehabilitation Hospital, Scranton PA. Patients unable to complete the survey due to of cognitive impairment or medical condition without a responsible party capable of consent or refusal to participate were excluded. Institutional review board approval was secured prior to initiation of the study. Mann-Whitney U Tests were used to assess the survey responses for patients taking warfarin as compared with NOACs.

Results: In total, 78 patients receiving oral anticoagulation therapy consented to participation and were surveyed. 37 patients were taking a NOAC (dabigatran n=2, rivaroxaban n=5, Apixaban n=30) and 41 patients were receiving traditional warfarin therapy. The survey results showed that majority of patients, regardless of anticoagulation therapy, disagree that they

have been previously educated regarding anticoagulation therapy options (69.2%, n=54), disagree that they were capable of choosing the anticoagulation therapy option of their choice (84.6%, n=66), disagree that they are aware of the varying costs of anticoagulation therapy options (68%, n=53), disagree that they have been educated regarding the differences in effectiveness between anticoagulation therapy options (61.5%, n=48), and agree that they prefer to be part of the decision-making process when selecting an anticoagulant (62.8%, n=49). Majority of patients taking NOACs agree that they understand the importance of medication compliance as compared with warfarin (59.4%, n=22). They also agree that they feel confident that their provider has supplied them with adequate information regarding the available anticoagulation therapy options and their varying options for reversal of effects if necessary (54.1%, n=20). Majority of patients taking warfarin disagree that they understand the differences in laboratory monitoring between warfarin and NOACs (78.0%, n=32).

Conclusion: In conclusion, the data suggests that patients receiving oral anticoagulation therapy are lacking knowledge regarding the safety, efficacy, and costs of the varying medication options available to them. Patients can potentially benefit from other therapy options; however, without adequate education, patients may not fully understand the optimal medication for their clinical and personal needs. These results show the need for a patient-centered approach and the need to engage patients in shared decision-making discussions. With the broader selection of oral anticoagulants available, assisting patients in choosing a therapy option based on clinical and personal circumstances can be essential for optimal care.

Submission Category: General Clinical Practice

Submission Type: Descriptive Report

Session-Board Number: 2-308

Poster Title: Validation of an evidence-based screening process through correlation with medication-related problems detected during evaluation by a clinical pharmacy service.

Primary Author: Emily McGrath, Wilkes University, Pennsylvania; **Email:** emily.mcgrath@wilkes.edu

Additional Author (s):
Corey Haupt
Dana Manning
Judith Kristeller

Purpose: Screening with evidence-based criteria for medication reconciliation can effectively identify and prioritize patients at risk of medication-related problems (MRPs). Institution-specific screening criteria should identify patients who are most at risk so that time and resources are directed at patients who will most likely benefit. Screening criteria should exclude patients unlikely to benefit from clinical intervention.
The purpose of this study is to validate an evidence-based screening tool by correlating the priority score assigned to the patient upon screening to the number and severity of MRPs discovered so that a pharmacy service can intervene and aid in resolving discovered MRPs.

Methods: Patients were included if they had been screened using our evidence-based screening tool and had undergone full work-up by the clinical pharmacy service. This service consists of clinical pharmacists and pharmacy students who collaboratively provide pharmaceutical care to patients. As part of screening, each patient was assigned a Comorbidity-Polypharmacy Score (CPS) and a pharmacy risk factor score (PRS). A CPS score is calculated by awarding one point for each disease state and one point for each home medication, representing a broad depiction of the patient's specific risk of MRPs.
A PRS score is calculated by awarding one point for each of the following disease states: heart failure, hypertension, history of myocardial infarction, coronary artery disease, COPD, diabetes, or chronic kidney disease. One additional point per medication was added if the targeted medication is classified as either an antihypertensive, anticoagulant, antiarrhythmic, inhaler, or glycemic control agent. One point is then allotted if the patient is taking ≥ 5 chronic

medications, and one additional point for each of the following: VTE, antiplatelets, anti-infectives, age > 65, age > 80, alcohol/drug abuse, smoking, history of falls.
MRPs found during evaluation were recorded by error type and drug class and were then assigned a severity score based on the potential harm they could cause as categorized by the National Coordinating Council for Medication Error Reporting and Prevention (NCC-MERP) index.

Results: A total of 87 hospitalized patients were included for analysis. The data was analyzed by comparing the screening CPS and PRS scores of each patient to the number of errors detected upon full evaluation and to the subsequent classification of severity of those errors. A positive correlation (r2= 0.297) was noted between the patient's score on the CPS scale and the absolute number of errors identified for each patient. The upward correlation indicates that comparing these two values together suggests that the CPS component of the screening criteria successfully identified high risk patients. A weaker positive correlation was observed between the pharmacy risk score and the total number of errors for each patient (r2 = 0.077). The PRS is more specific to our institution and contains a more restricted evaluation of patient population, thus creating a weaker trend line. Combining the PRS and CPS scores also resulted in a positive correlation trend (r2 = 0.283), indicating that a composite scoring approach would also successfully allow for identifying high risk patients.

Conclusion: This study showed that our evidence-based screening criteria did identify patients with the highest number of MRPs identified during evaluation. While our screening criteria utilized two separate scores to help identify the high-risk patient, it appears that the broader CPS system was better at identifying patients with potential MRPs. However, the PRS contains criteria that was specifically relevant to our institution's needs and therefore is a complementary data point to the CPS. Together, the positive correlation seen by comparing these two data points expresses that the screening criteria aids in selecting patients most likely to benefit from our clinical service.

Poster Title: Establishment of an evidence-based screening criteria for an inpatient clinical pharmacy service focused on transitions of care.

Primary Author: Corey Haupt, Wilkes University, Pennsylvania; **Email:** corey.haupt@wilkes.edu

Additional Author (s):
Elena Stambone
Judith Kristeller
Dana Manning

Purpose: While all patients admitted to the hospital receive a basic reconciliation of their home medication use, patients at high-risk of medication related problems (MRPs) would benefit from a more thorough evaluation of their acute and chronic medication therapy. Identifying patients who would benefit the most from a comprehensive medication review will improve safety when transitioning the patient from hospital to home. Establishing an evidence-based tool for patient screening will facilitate the work of a clinical pharmacy service by targeting their efforts towards patients at greatest risk of MRPs.

Methods: The literature was searched for publications that evaluated risk factors predisposing patients to medication errors and readmissions within 30 days. A policy and procedure document was developed from this information outlining the risk factors gathered from the research and the screening process to be followed by the clinical pharmacy service.
Patients were considered eligible for the service if they were admitted from a non-institutional setting and did not have active cancer or admission for elective surgery, obstetric care, or active psychiatric issues. If a patient was considered eligible for the service, they were then scored on two separate scales - the pharmacy risk score (PRS) and the comorbidity-polypharmacy score (CPS). The CPS was calculated by adding the total number of comorbidities to the total number of home medications.
The (PRS) alots one point for the following criteria - disease states (heart failure, hypertension, history of myocardial infarction, coronary artery disease, COPD, diabetes, or chronic kidney disease), medications (antihypertensives, anticoagulants, antiarrhythmics, inhalers, and glycemic control agents), and risk factors (>5 chronic medications, VTE, antiplatelets, anti-infectives, age > 65, age > 80, alcohol/drug abuse, smoking, history of falls). Patients with higher

scores in each scale as well as in total were considered more at risk and of higher priority for intervention.

Results: After screening three floors (72 patients), a total of 32 patients were found to be eligible for the service (44%). PRS score was divided into four quartiles, with the lowest 25% being patients at the lowest risk for MRPs and the highest 25% being patients at highest risk for MRPs. The lowest 25% of scores ranged from 1-4, the middle two quartiles ranged from 5-8 and 9-12, and the highest 25% of scores were above 12. 9% of patients fell into the lowest 25%, while 18% of patients fell into the highest 25% of scores. The remainder (36%) of patients fell in the middle two quartiles.

The CPS scoring broadly evaluated patients at risk for MRPs. CPS scores are able to further distinguish between low risk and high risk patients and ranged from 6 to 31, with 31 being the most at risk patients. The lowest 25% of scores ranged from 1-12, the middle two quartiles ranged from 13-17 and 18-22, and the highest 25% of scores above 23. 6% of patients fell into the lowest 25%, while 48% and 27% of patients fell into the middle two quartiles, and 15% of patients fell into the highest 25% of scores.

Conclusion: Developing evidence based screening criteria allowed us to find, score, and prioritize patients to be cared for by a clinical pharmacy service. Score distribution analysis showed most patients had scores in the middle but that there was a proportion of patients scoring either very high or very low. Given this information, we can establish guidelines for patient prioritization and when patients should be seen by a service with limited time and resources. Patients with the highest PRS along with the highest CPS score would benefit most from this service, as they are considered to be at highest risk for MRPs.

Poster Title: Evaluation of Pharmacy Interventions in a Primary Care Physician Office

Primary Author: Luke Zack, Wilkes University Nesbitt School of Pharmacy, Pennsylvania; **Email:** luke.zack@wilkes.edu

Additional Author (s):
Rebecca Gordon
Thomas Franko
Brittany Wills
Lauren Lockus

Purpose: Medication errors can occur at various stages including prescribing, transcribing, dispensing, administration, and patient follow up. According to a report from the Institute of Medicine, medication errors injure 1.5 million Americans each year and cost $3.5 billion. However, complete pharmaceutical care has shown to decrease these risks.
Pharmacists joined a collaborative agreement at The Wright Center, a primary care clinic where they interact with a variety of patients with complex drug regimens. The implementation of a pharmacist and their knowledge of pharmacotherapy into this care team is an important component in the management of illness and chronic diseases.

Methods: An observational retrospective chart review was performed to compare the number of interventions made per number of patients seen from two separate six month periods, October - March 2014/2015 and October - March 2015/2016. During this time, 1,017 patients were documented as receiving pharmacist intervention. A Mann-Whitney test was used to compare the two groups.

Results: The Mann-Whitney test indicated that there was no significant difference between interventions made between years (P-value was 0.337).

Conclusion: No significant difference of number of pharmacy interventions was found between the two years. This shows that the number of interventions made by pharmacists were consistent for two years which signifies the willingness of the medical team to take pharmacists

on board in a state where inpatient pharmacy is new and unfamiliar. These results demonstrate the benefits of a pharmacist in collaborative practice and warrant further investigation.

Poster Title: Implementation of a twice-daily medication pass program in a long term care facility

Primary Author: Shannon Gilhooley, Wilkes University Nesbitt School of Pharmacy, Pennsylvania; **Email:** shannon.gilhooley@wilkes.edu

Additional Author (s):
Dominick Trombetta

Purpose: Administration of medications in long term care facilities is a labor intensive process that consumes a large portion of nursing time. Complex medication regimens contribute to this extensive time commitment which may limit nursing time available to provide residents with high quality, individualized care. Pharmacists can help address this problem by finding ways to simplify the daily medication administration process. This project was designed to reduce the complexity of resident medication regimens in order to decrease the nursing time dedicated to medication administration in a long term care facility.

Methods: Over a two-month period between December 2015 and January 2016, a "Twice-Daily Medication Pass Program" was implemented at a long term care facility in Carbondale, Pennsylvania. An inter-professional team of pharmacists, physicians, and nurses worked together to augment the medication regimens of 80 residents to conform to a twice-daily administration schedule when possible. Monthly physician order sheets were faxed and reviewed by a pharmacist on a weekly basis. The pharmacist evaluated the medication regimen of each individual patient and used clinical judgment to make appropriate recommendations to change complex medication orders to twice-daily regimens. Typed recommendations were sent to the director of nursing and then forwarded to the prescribing physician. Prescription orders were changed to reflect the pharmacist recommendations when deemed appropriate by the prescribing physician and the simplified medication regimen was then employed. Following implementation of the program, data was collected to quantify the acceptance rate of pharmacist recommendations. Residents involved in the program that were discharged or deceased at the time of data collection were not included.

Results: A total of 66 residents were considered in the collection of data following implementation of the program. The average number of maintenance prescription orders per resident was 10.9 and the total number of prescription orders for all residents was 723. There were a total of 45 pharmacist recommendations that were made to simplify complex medication regimens to follow a twice-daily schedule. Of these recommendations, 36 (80 percent) were accepted by the physician and resulted in a prescription order change and 9 (20 percent) were rejected. The 36 accepted pharmacist recommendations equated to approximately one medication regimen change for every two patients considered in the data collection.

Conclusion: Implementation of a Twice-Daily Medication Pass Program was an effective strategy to simplify medication administration in a long term care facility. Through a collaborative effort between facility staff, prescription orders were changed to adhere to a simplified twice-daily regimen. This program provides one example of an important role for pharmacists on an integrated healthcare team. Simplifying a complex medication regimen provides an inexpensive and feasible opportunity for pharmacists to help decrease nursing time devoted to medication administration.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Descriptive Report

Session-Board Number: 2-312

Poster Title: Inter-professional collaboration between pharmacy and nursing to improve hospital wide medication distribution process

Primary Author: Amanda Gerberich, Wilkes University Nesbitt School of Pharmacy, Pennsylvania; **Email:** amanda.gerberich@wilkes.edu

Purpose: Medications that are unavailable to nursing at time of medication administration can impede on patient care and create additional work for both nursing and pharmacy staff. Furthermore dispensing an additional dose of a medication costs an average of 25 dollars, equating to more than 225,000 dollars per year for the institution. To understand the cause and decrease the amount of missing medications at time of administration, the Black Belt Committee was formed. The committee consisted of pharmacy staff and nurses independent of management.

Methods: The Black Belt Committee created standard work for nursing, pharmacy, and department leadership. All pharmacy staff and participating nursing units utilized the standard work during the pilot. Three medication distribution workflows were piloted by the pharmacy technicians to examine the amount of unavailable medications at the time of administration, with a goal of 8 percent improvement from baseline. Secondary metrics included medication preparation cycle time and length of hourly medication delivery runs. Goals of secondary metrics were to improve medication preparation time by 43% and no increase in medication delivery run time. Additionally daily steps were monitored for each pharmacy technician to consider workflow burden. Workflow A utilized two pharmacy technicians for delivery runs to the entire hospital and one technician to prepare medications in the pharmacy. Workflow B along with the baseline workflow utilized three pharmacy technicians for delivery runs; all technicians shared medication preparation responsibilities when they returned from runs.

Results: Workflow B, which utilized three pharmacy technicians, was adopted by the pharmacy department based on a 19% decrease in unavailable medications at time of administration from baseline (357 vs. 289 errors per 1000 patient days). Medication preparation time was decreased by 43% from baseline (52 vs. 29 minutes). Medication run cycle time did not change.

Conclusion: Collaboration between pharmacy and nursing staff provides a well-rounded evaluation of the medication distribution process from processing to administration. Utilizing staff that are directly involved in the medication distribution process, specifically nurses, pharmacy technicians, and pharmacists allows the team to best identify the challenges faced in the process. An ongoing effort must be made to ensure safe and efficient medication distribution by the Black Belt Committee through monthly monitoring.

Poster Title: Hospital consumer assessment of healthcare providers and systems (HCAHPS) survey results after implementation of unit-based pharmacists into key hospital services

Primary Author: Alex Shreiber, Wilkes University Nesbitt School of Pharmacy, Pennsylvania; **Email:** alex.shreiber@wilkes.edu

Additional Author (s):
Jill Rebuck

Purpose: Since the implementation of hospital value based purchasing, health systems strive to improve patient outcomes and patient satisfaction survey results. The Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) survey currently serves as the standardized measuring tool to evaluate a hospital's performance. Recently, our institution increased the number of unit-based pharmacists to collaborate within inter-professional teams and improve patient–focused outcomes. This retrospective review evaluates if recent implementation of expanded pharmacist services in the acute care medicine service line impacted HCAHPS scores.

Methods: Patient satisfaction data from a defined inpatient medicine service nursing unit at our health-system were reviewed over two consecutive time periods (July 2014 to June 2015 and July 2015 to June 2016), consistent with an increase in intensity of pharmacy services provided during year two. Responses to HCAHPS surveys were evaluated, focusing on questions associated with potential for direct pharmacist bedside educational interventions. The three analyzed questions included patient understanding of both purpose and indication of prescribed medications, and explanation of potential side effects associated with new medications administered during the inpatient hospitalization. Acute care medicine services lines were defined as patients discharged from either internal medicine or family community medicine. These two services received the most benefit from expanded unit-based pharmacist roles during the time frame analyzed, with expansion of service occurring during year two. Documented pharmacy interventions specific to education of patient and/or family members were compared during the two time periods. Results were evaluated against improvement in patient satisfaction scores in the communication regarding medication categories.

Results: Documented pharmacist bedside education interventions specific to medicine service patients admitted to our health-system totaled 81 during year one and 969 in year two during the evaluation period, representing a 12-fold increase in educational bedside medication counseling interventions during year two. The top three most frequent medication categories associated with patient bedside educational interventions performed by pharmacy included anticoagulant (38.2%), diabetes (17.3%), and respiratory inhaler-related (13.8%) regimens. Increases in the percentage of responses categorized as "always" were reported in all three medication related communication domain questions surveyed. Compared to year one, increases of 5.9% and 6.9% were demonstrated in positive "always" responses to understanding indication and purpose of medications, respectively, during year two. Additionally, a 2.6% improvement in "always" response to hospital staff describing medication side effects was also noted during year two. No new practices regarding medication communication were implemented by other non-pharmacy disciplines during the evaluation period.

Conclusion: Pharmacist's further integration into inter-professional teams as demonstrated by enhanced patient bedside medication education had a positive impact on HCAHPS scores when examining medication related communication domains of the HCAHPS survey. This correlated with a substantial increase in pharmacy interventions year-over-year for our institution. Over the specified one-year period, aggregate scores improved, indicating enhanced patient perceived quality of care surrounding medication communication.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Evaluative Study

Session-Board Number: 2-314

Poster Title: Medication use evaluation: Appropriate aspirin use for treatment and prevention of cardiovascular disease

Primary Author: Sarah Brozena, Wilkes University Nesbitt School of Pharmacy, Pennsylvania; **Email:** sarah.brozena@wilkes.edu

Additional Author (s):
Vicky Shah

Purpose: Aspirin 325 mg is very effective for certain indications, but inappropriate chronic use can cause an increased risk of bleeding. Aspirin 325 mg can be used as a single dose for pain or when an acute coronary syndrome or cerebrovascular accident has just occurred. It can also be used daily to prevent thromboembolism in patients with atrial fibrillation who are not candidates for other therapy. The purpose of this study was to determine if the appropriate aspirin dose is being administered in the hospital, and if patients are being discharged on the appropriate dose.

Methods: The Wilkes-Barre Veterans Affairs Medical Center approved this medical use evaluation. The medical health records of twenty-four patients on the general inpatient ward from a six month time period were analyzed. Every administration of aspirin 325 mg was investigated to determine the indication. Patient's home medication list on admission and discharge were also analyzed to track any change in aspirin use.

Results: When administered in the hospital, aspirin 325 mg was used for appropriate indications in fourteen patients (58.3%). Twelve patients had indications for treatment of acute coronary syndrome or cerebrovascular accident. Two patients had indications for atrial fibrillation anticoagulation. Ten patients (41.6%) had no appropriate indication for aspirin 325 mg. The indication and dose of aspirin was also analyzed upon patient discharge. Upon discharge, eleven patients (45.8%) were prescribed appropriate aspirin treatment. Nine patients continued or were switched to aspirin 81 mg for cardiovascular disease prevention. Two patients appropriately continued aspirin 325 mg for atrial fibrillation. One patient (4.2%) discontinued the use of aspirin for cardiovascular disease prevention. In comparison, twelve patients (50%) were prescribed inappropriate aspirin treatment upon discharge. Ten patients

initiated or continued aspirin 325 mg for cardiovascular disease prevention. One patient continued aspirin 325 mg with no indication and one patient switched from aspirin 81 mg to 325 mg.

Conclusion: Aspirin 325 mg is frequently being used for inappropriate indications in the hospital setting. It is also being prescribed for cardiovascular disease prevention upon discharge even though aspirin 81 mg has been shown to provide the same benefit with lower risk of bleeding. Proper evaluation of aspirin dose and indication could potentially prevent future patient morbidity and mortality.

Submission Type: Descriptive Report

Session-Board Number: 2-315

Poster Title: Evaluation of Opioid Prescribing Amounts in a Primary Care Physician Office.

Primary Author: Jesse Kita, Wilkes University Nesbitt School of Pharmacy, Pennsylvania; **Email:** jesse.kita@wilkes.edu

Additional Author (s):
Thomas Franko

Purpose: The opioid crisis in America may be attributed to several factors, one of which is overprescribing. In an effort to provide structure to the use of opioids for chronic pain, the Centers for Disease Control (CDC) issued guidelines recommending max daily doses of opioid medication (≥90 mg MME). These guidelines served as a compliment to the existing recommendations set by the Pennsylvania Medical Society (≥100 mg MME), currently used as clinic policy. The aim of this study is to determine the amount of patients in a primary care physician office taking more than the recommended amount of opioid per day.

Methods: All patients prescribed any opioid medication from a clinic provider between 8/1/16 and 9/20/16 were included. Prescription information, including medication, dose and frequency, was queried from the electronic health record for the designated date range. All opioids prescribed for each qualified patient was totaled for a calculated daily dose represented as mg of morphine or morphine equivalent (MME). Total daily doses were then placed into one of three groups: 0-49 mg, 50-99 mg, and ≥100 mg, in order to correspond with both CDC and Pennsylvania Medical Society recommendations.

Results: 39 patients were included in the study. 69% (27) were found to be in the range of 0-49 mg/day MME. 21% (8) were within 50-99 mg/day of MME, though none of the patients were above 90 mg/day of MME. 10% (4) were found to exceed the limit of ≥100 mg/day of MME.

Conclusion: Four patients were prescribed over the recommended daily amount of opioid medication per Pennsylvania Medical Society and CDC recommendations. In an effort to better comply with these guideless, this patient population will be scheduled for a joint visit with the physician and a pharmacist within one month. At this visit, various methods will be discussed to

reduce the total opioid use and use other pharmacologic and non-pharmacologic methods to address their pain control.

Poster Title: Risk stratification of patients with diabetes mellitus in an inpatient internal medicine service at an academic medical center

Primary Author: Amy Davies, Wilkes University Nesbitt School of Pharmacy, Pennsylvania;
Email: amy.davies@wilkes.edu

Additional Author (s):
Jill Rebuck

Purpose: Evaluating patient factors assists pharmacists target those at higher risk for hospitalization and thereafter, readmission. Readmission within 30 days of discharge is a major contributor to decreased reimbursement rates and dissatisfying to patients. Identifying risks for readmission may decrease readmission and maximize pharmacist time by focusing on those most in need of counseling. Patients with diabetes are at an increased risk of complications including frequent hospitalizations. This project was designed to identify factors pertinent to pharmacist recognition of which patients admitted with diabetes are most likely to be readmitted and help understand which interventions benefit these patients most.

Methods: A literature search was conducted to identify patients with diabetes and how their medications or other disease state management characteristics may impact educational needs. Subsequently an eight question survey was designed and validated to assess which characteristics clinical pharmacists within our institution believed were most important influencers of patient complexity, including likelihood of readmission. Survey content included patient assessment of various laboratory parameters, medication number and type, and comorbid conditions related to prioritization practices of pharmacists for patient selection of medication counseling. Multiple diabetic medication choices were assessed including insulin, metformin, sulfonylureas, meglitinides, and thiazolidinediones. Comorbid conditions in patients with diabetes including heart failure, autoimmune disorders, chronic kidney disease, pain management, infection, and chronic obstructive pulmonary disease were considered. Frequency of diabetic medication therapy changes during the acute hospitalization and continuation post-discharge were included. The survey also identified the percentage of patients who receive proper education regarding diabetes management and related counseling barriers based on pharmacist experience.

Results: Thirteen of 17 clinical pharmacists at our institution completed the survey (77% response rate) regarding their experience managing patients with diabetes and related inpatient care. Pharmacists identified hemoglobinA1c (92%), blood glucose levels (69%), and insulin dependency (54%) prior to admission as the three most important factors to assess a patient with diabetes during daily chart review. Characteristics which were perceived as highest priority for identifying the need to counsel patients with diabetes included low health literacy (62%), elevated hemoglobinA1c (62%), and extremes of blood glucose levels upon presentation (77%). The diabetic medications most frequently associated with pharmacist-based counseling were insulin (92%), metformin (46%), and sulfonylureas (38%). Based on survey responses, heart failure (92%), chronic obstructive pulmonary disease (77%), and chronic kidney disease (46%) were the comorbid conditions most often related to frequent hospitalizations in patients with diabetes. Pharmacist-initiated medication therapy changes occur in 42% of patients per report. Proper diabetes education is necessary in 66% of patients based on pharmacist experience. The greatest obstacle identified to successful patient counseling during the inpatient stay was low health literacy.

Conclusion: At our institution, pharmacists have an important role in identifying patients with diabetes who may benefit from further education and bedside counseling.

Submission Category: Quality Assurance/ Medication Safety

Session-Board Number: 2-317

Poster Title: Are statins associated with muscular complaints in dialysis patients? Results from a double blind cross-sectional study.

Primary Author: Letitia Warunek, Wilkes University Nesbitt School of Pharmacy, Pennsylvania; **Email:** letitia.warunek@wilkes.edu

Additional Author (s):
Sarah Hassinger
Edward Foote

Purpose: There is little research involving the use of statins in hemodialysis patients as it relates to drug interactions and side effects. During routine medication reviews in our hemodialysis unit, it appeared that patients on statin therapy were experiencing a high incidence of muscle symptoms. There is no data on the relationship between muscle pain and statin therapy in hemodialysis patients. These anecdotal observations prompted this study in order to answer the clinical question, "Do hemodialysis patients on moderate or high intensity statins have a higher incidence of muscular complaints compared to dialysis patients not on statins?"

Methods: The institutional review board at Wilkes University approved this double-blind cross sectional study. This study was conducted at three local Fresenius Medical Care Hemodialysis Units in April of 2016. A questionnaire inquiring about muscle complaints (pain, discomfort, cramping, weakness) was developed and administered orally to patients at the dialysis units. Study investigators were blinded to the use of statins during the interviews. Patients were blinded in that they were unaware of the purpose of this study. After all questionnaires were completed, home medication lists were generated for all participants from the electronic medical record system at the dialysis units. Participants were grouped by the use (or non-use) of statin therapy (predictor variable). In patients on statins, the medication name, dose, and frequency were documented. Patients were excluded from the analysis if they were taking a low intensity statin. The primary outcome of the study was the incidence of muscular complaints in statin versus non-statin patients compared using chi-square analysis.

Results: Questionnaires were administered in April of 2016. There were 202 patients eligible for participation. Of these, 10 patients were not approached due to language barrier (6), nursing recommendation (2), dementia (1), and hearing loss (1). In addition, 17 patients declined participation, leaving 175 patients consented for participation. Ten patients were subsequently excluded from analysis because they were on a low intensity statin (9) or had no active medication list (1). 72 percent of patients on statins reported muscular symptoms within the past four weeks compared to 71 percent not on statins. An equal proportion described the complaints as bilateral (59 percent vs. 62 percent). However, 52 percent of the patients on statins reported having other potential causes of pain compared to 81 percent of the non-statin group (p-value less than 0.05), putting into question the overall lack of contribution of muscular complaints by statins.

Conclusion: Based on results from this study, moderate and high intensity statin therapy does not appear to be associated with an increased incidence of muscular complaints in hemodialysis patients, but more research is needed.

Poster Title: Pharmacy students improve medication management through home care visits

Primary Author: Kristen Lopatofsky, Wilkes University Nesbitt School of Pharmacy, Pennsylvania; **Email:** kristen.lopatofsky@wilkes.edu

Additional Author (s):
Judith Kristeller

Purpose: Patients receiving home health often have complex medication regimens and an increased risk for medication-related problems. Currently, pharmacists have a limited role in home health, however there is great opportunity to optimize medication management by visiting patients in their home. In this environment, pharmacists or pharmacy students can assess medication management, identify opportunities to improve adherence, and provide patient education. The purpose of this research is to quantify and categorize the number of medication-related problems that pharmacy students identify that lead to improved medication management.

Methods: At Wilkes University, pharmacy students in their third professional year are enrolled in a service-learning course where they meet with a patient in their home bi-monthly throughout the academic year. A survey was developed and piloted to quantify and categorize student clinical activities during these home visits. Within 48 hours after each home visit, the pharmacy student completes the survey, answering questions pertaining to the time spent with the patient, the quality of the interaction, actions taken during the visit, the type of medication-related problem(s) identified, any recommendations made, and if the student communicated with another healthcare professional to resolve medication-related problems. Medication-related problems were categorized as undertreatment (untreated condition or additional treatment recommended), suboptimal regimen (recommend change in dose, duration, administration or frequency), medication monitoring recommended, suboptimal drug (no indication, duplication, not effective, unsafe, or cheaper alternative available), adverse drug event, and medication non-adherence.

Results: Seventeen responses representing 17 visits were collected from 13 pharmacy students after the first few home visits of the 2016 Fall semester. Over half of the students spent more than 60 minutes with their patient with nine reporting they had a "high quality experience." Most students indicated that they provided care and comfort to their patient or developed a rapport with the patient. Students provided patient education pertaining to over-the-counter medication use during 11 of 17 visits (65 percent). Another common intervention was a discussion with patients about the importance of medication adherence as reported by eight students. Education was also provided about medications, disease states, or allergies by six students. Six medication-related problems were reported for the 17 responses. Of the six medication-related problems, 3 were classified as suboptimal treatment and there was one each classified as undertreatment, medication monitoring, and non-adherence. Four students provided patient education based on a medication-related problem with one student referring a patient to their health care provider. There were four reports of students communicating with their patient's other healthcare providers including a community pharmacist, care manager, nurse, and physical therapist.

Conclusion: Pharmacy home visits are an opportunity to improve the quality of care for patients with complex medication regimens. From the very beginning of this service-learning course, pharmacy students identified medication-related problems, provided patient education, and collaborated with other healthcare providers to improve care. This is an effective format for providing a meaningful and educational experience for students while also promoting the safe and effective use of medications.

Poster Title: Evaluation of medication related problems and errors identified during pharmacist-led medication reconciliation

Primary Author: Heidi Yanoski, Wilkes University Nesbitt School of Pharmacy, Pennsylvania;
Email: heidi.yanoski@wilkes.edu

Additional Author (s):
Corey Haupt
Judith Kristeller
Dana Manning
Michele Musheno

Purpose: Moses Taylor Hospital is a 217 bed facility located in Scranton, PA. Currently, admission medication reconciliation is completed by a non-pharmacist. When medication reconciliation is completed by pharmacists, it can be used as the initial step in a comprehensive medication review. Pharmacist-led medication reconciliation can lead to a more accurate home medication list and facilitate a comprehensive assessment of medication management to identify medication-related problems (MRPs). The purpose of this study is to quantitatively and qualitatively analyze medication errors identified on the home medication list and MRPs identified during pharmacist-led medication reconciliation and review in high-risk patients.

Methods: We defined high-risk patients as those taking at least five chronic medications and having multiple chronic disease states. Only patients with a planned discharge to home were invited to participate. Exclusion criteria included active cancer, significant cognitive impairment, hospice care, and admission for elective surgery. After identifying high-risk patients, pharmacists completed a medication reconciliation and a comprehensive medication review. The admission home medication list previously completed by a non-pharmacist was verified during a conversation between a pharmacist and patient, then any medication errors were corrected. These errors in the home medication list and any additional MRPs identified by the pharmacist were quantified and categorized based on drug class and type of error or problem. Medication errors were classified as an incorrect dose or frequency, medication not prescribed, medication omission or allergy clarification. MRPs were categorized as under-treatment, suboptimal regimen, monitoring recommended, non-adherence, adverse drug event, or patient

education needed/provided. Medication errors and MRPs were further classified based upon validated severity criteria, ranging in severity from 1 to 9 (1: no error, 2: error did not reach patient, 3: likely no harm, 4: required monitoring to confirm no harm, 5: temporary harm, 6: initial or prolonged hospitalization, 7: permanent harm, 8: life support, 9: death). A total of 87 patients enrolled between August 2015 and June 2016 were included in this data analysis.

Results: During the study period, we identified a total of 680 medication errors and MRPs (average of 8 per patient) which were further divided into 499 errors and 181 MRPs. When considering both errors and MRPs, the majority of issues involved cardiovascular (20 percent), analgesic (12 percent), and pulmonary (11 percent) medications. The most common categories of medication errors identified was change in the dose, frequency, or formulation of the medication (43 percent), medication omission (31 percent), and medication not prescribed (11 percent). The most common MRPs identified were the need for patient education (60 percent), patient non-adherence (10 percent), and medication under-treatment (9 percent). The severity level of all errors was also assessed as follows: level 1 (no error) 15.3 percent, level 3 (likely no harm) 74.6 percent, level 4 (required monitoring to confirm no harm) 6.4 percent, level 5 (temporary harm) 2.4 percent, level 6 (initial or prolonged hospitalization) 1 percent, level 7 (permanent harm) 0.3 percent. There were no errors or MRPs identified for levels 2, 8, or 9. While the percentage of patients with a severity of five or higher was low, this represented 23 higher-severity issues involving 20 patients.

Conclusion: Pharmacist-led medication reconciliation is an essential step in developing an accurate medication list and completing a medication review. We have demonstrated that medication reconciliation completed by non-pharmacists results in errors. Furthermore, pharmacist involvement in this process leads to improved medication safety especially related to cardiovascular, analgesic, and pulmonary medications. It is unlikely that these MRPs would have been addressed without a pharmacist-led process. While most errors or MRPs did not cause harm, 23 contributed to temporary or permanent harm. These results suggest investment in pharmacist-led medication reconciliation can improve the quality and safety of patient care through better medication management.

Submission Type: Descriptive Report

Session-Board Number: 2-320

Poster Title: Role and preliminary impact of a clinical pharmacist in a nephrology practice within a patient-centered medical neighborhood

Primary Author: Julia Jarmoszko, The University of Rhode Island, Rhode Island; **Email:** julia_jarmoszko@my.uri.edu

Additional Author (s):
Kelley Sanzen

Purpose: Chronic kidney disease is a complex disease state and patients experience multiple comorbidities including diabetes, hypertension, heart failure, anemia and more. Drug related problems are common in this population, which highlights the opportunity for clinical pharmacist services. While the role of pharmacists with hemodialysis and kidney transplant patients have been studied, there is less known about the benefits of a clinical pharmacist in an ambulatory care nephrology practice that is part of a medical neighborhood model of care. The objective of this project is to describe the role and preliminary results of a clinical pharmacist in this setting.

Methods: The clinical pharmacist was introduced to the nephrologists of the patient-centered medical neighborhood in June 2014 and collection of structured data in the electronic medical record for pharmacist services were reported from November 2014 through March 2016. Additionally, select patients for a regional payer had pharmacist interventions documented into a payer-contracted medication therapy management platform to estimate cost avoidance and return on investment of these services. Patients with chronic kidney disease identified for co-management between the nephrologist and primary care physician received a comprehensive medication review. Other pharmacy services were identified and implemented during this time period, most notably a protocol for using erythropoietin stimulating agents in the management of anemia for non-dialysis chronic kidney disease patients. Billing invoices were used as a proxy for demonstrating reduced pharmacy costs at one of the practices in the group. Pharmacy services were categorized in four groups: clinical services, disease state management, prescriber education and patient education.

Results: All clinical pharmacy services identified in the nephrology practice within the patient-centered medical neighborhood had preliminary results that indicate benefit. There were 294 chronic kidney disease patients co-managed by the pharmacist, 50 of which were included in the payer-contracted medication therapy management platform. The clinical pharmacist completed 291 encounters with 189 patients and identified 724 drug therapy problems, thus averaging 4 drug therapy problems per patient. Preventing inappropriate use of drugs and educating physicians about less expensive alternatives was observed to have great cost saving potential in this setting. Discontinuation of corticotropin (Acthar) in two patients avoided potential drug costs of over one million dollars in the 2015 calendar year. Protocol development for erythropoietin stimulating agents use influenced safe prescribing habits and decreased utilization of expensive drugs. The office spending on darbepoetin alfa (Aranesp) decreased by over eighty percent when invoices from October 1, 2014 through September 30, 2015 were compared to those from October 1, 2015 through Sept 30, 2016. Other valuable pharmacy services included blood pressure checks, ordering labs, patient education, adherence monitoring, prior authorization support and more. However, there was insufficient data to provide accurate cost savings and outcome information for all pharmacist interventions.

Conclusion: The patient-centered medical neighborhood presents valuable intervention opportunities for clinical pharmacists to improve patient care in a nephrology centered practice. Preliminary interventions have resulted in reduced costs; however, the true cost savings potential cannot be determined at this time.

Poster Title: Assessing the usefulness of an online chat room in the integrated renal and cardiovascular courses

Primary Author: Thomas Szymanski, The University of Rhode Island College of Pharmacy, Rhode Island; **Email:** tszymanski@my.uri.edu

Additional Author (s):
Gina Villano
Nicole Asal
Marilyn Barbour

Purpose: Pharmacy students in their first professional year (P1) often struggle to adapt to the demands of the rigorous curriculum. The integrated renal and cardiovascular courses at the University of Rhode Island (URI) College of Pharmacy facilitate learning of renal and cardiovascular disorders and the medications used to treat them. The primary goal of this project was to evaluate the usefulness of an online chat room as a supplemental learning tool in these courses.

Methods: The online chat room function of the course management system at URI (Sakai) was offered throughout the spring semester to P1 students. Two students in their third professional year (P3) collaborated with the professor who taught a particular topic to determine the optimal time and date to hold the chat room. This time and date was communicated to students via Sakai announcements and email. In the chat room, P1 students were able to submit questions in a real-time list format. The P3 students or professor then responded to the questions and posed questions to the students to encourage discussion.
At the end of the semester, the students were asked to fill out a brief, electronic survey via Survey Monkey. The survey asked 12 questions about the chat room, including asking if they attended the chat room and, if they did not, the reason(s) why, and the impact of the chat room on their learning. The survey was approved by the URI Institutional Review Board.

Results: A total of 63 students completed the survey. Seventy percent reported that they attended the live chat room, and 95 percent viewed the archived chat room.

Thirty-nine percent of respondents agreed that the chat room encouraged them to stay up-to-date with their studying versus 16 percent who disagreed and 45 percent who neither agreed nor disagreed. Seventy-seven percent of respondents agreed that the chat room encouraged student-faculty interaction outside of class versus 3 percent who disagreed and 20 percent who neither agreed nor disagreed. Sixty-two percent agreed that the chat room helped them learn more by asking their own questions and seeking answers versus 7 percent who disagreed and 31 percent who neither agreed nor disagreed. Seventy percent of respondents agreed that the chat room facilitated their learning versus 5 percent who disagreed and 25 percent who neither agreed nor disagreed. Eighty-two percent of respondents agreed that the chat room clarified material that they did not understand versus 3 percent who disagreed and 15 percent who neither agreed nor disagreed. Sixty-four percent agreed that it encouraged them to ask questions about the material versus 11 percent who disagreed and 25 percent who neither agreed nor disagreed.

Conclusion: Based on the results of the survey, the online chat room is a useful adjunct that P1 students can use to enhance their understanding of the renal and cardiovascular course material. Overall, the chat room encouraged students to stay up-to-date in their studying, encouraged student-faculty interaction outside of class, helped them learn more by asking their own questions, facilitated their learning, clarified material they did not understand, and encouraged them to ask questions about the material. The feedback provided by the students who participated can be used in the future to further improve the chat room.

Poster Title: Adherence to the 2013 American college of cardiology/American heart association cholesterol guideline recommendations in patients with stroke

Primary Author: Karolina Wojciak, University of Rhode Island, Rhode Island; **Email:** kwojciak@my.uri.edu

Additional Author (s):
Jayne Pawasauskas
Michelle Kelley

Purpose: Ischemic stroke accounts for 87% of all stroke events and about 14% of stroke survivors experience a recurrent stroke within a year. Adjusting for hypercholesterolemia with statin therapy has contributed to reducing stroke mortality. The 2013 ACC/AHA Cholesterol Guideline includes recommendations for both the primary and secondary prevention of ischemic stroke by modifying LDL-C levels in four statin-benefit groups. The purpose of this study was to evaluate if patients admitted for ischemic stroke or transient ischemic attack (TIA) were discharged with a statin and whether the statin prescribed was appropriate in accordance with the 2013 ACC/AHA Cholesterol Guideline.

Methods: A single-center, institutional review board-approved, retrospective chart review was conducted using electronic medical records from April 1, 2015 to April 1, 2016. Patients who were at least 21 years of age and diagnosed with either ischemic stroke or TIA were considered for inclusion (n equals 368). Patients whose electronic medical records lacked a lipid panel, who were misdiagnosed with ischemic stroke or TIA on admission, who were transferred to another hospital or hospice, or who expired were excluded (n equals 56). The primary outcome was the proportion of patients who were discharged on an appropriate statin for the secondary prevention of stroke. Using the 2013 ACC/AHA Cholesterol Guideline, statin intensity was determined to be appropriate based on the patient's age, renal function, history of rhabdomyolysis and statin intolerance, history of heart failure, and whether the patient was undergoing maintenance hemodialysis. Secondary outcomes included pharmacist intervention and 30-day readmission with ischemic stroke or TIA. Subgroup analysis was performed in patients more than 75 years of age, patients with a history of heart failure, and patients who were undergoing maintenance hemodialysis.

Results: A total of 189 (60.58%) patients were diagnosed with ischemic stroke and 123 (39.42%) were diagnosed with TIA. There were 130 (41.67%) appropriate discharges with statin therapy, 97 (31.09%) inappropriate discharges, and for 85 (27.24%) patients it was uncertain whether statin therapy at discharge was appropriate as the guideline did not make clear recommendations in individuals more than 75 years of age, patients with a history of HF, and patients undergoing maintenance HD. NYHA HF class was not included in electronic medical records therefore all patients who had a documented history of heart failure needed more information to determine if statin therapy at discharge was appropriate. A total of 55 pharmacist interventions were recorded and out of the interventions that were evaluated (n equals 42), only four were determined to be inappropriate. Six out of the 40 patients who were readmitted experienced a subsequent ischemic stroke or TIA, however not enough patients were readmitted within 30 days of discharge with ischemic stroke or TIA to develop a correlation between statin therapy at discharge and readmission.

Conclusion: Educating the recommendations provided by the 2013 ACC/AHA Cholesterol Guideline and initiating a protocol for determining the appropriateness of statin therapy at discharge for the secondary prevention of ASCVD events would benefit both patients and health care professionals at Kent Hospital. As the Expert Panel suggested, future guidelines could examine subgroups of individuals with HF and/or individuals undergoing maintenance HD who might benefit from statin therapy. Likewise, more guidance is needed to determine appropriate statin intensity in individuals more than 75 years of age who are continuing statin therapy.

Poster Title: The impact of student led onsite academic detailing on pneumococcal vaccinations in retail pharmacy

Primary Author: Marisha Okpala, University of Rhode Island, Rhode Island; **Email:** marisha_okpala@my.uri.edu

Purpose: The ease of accessibility of retail pharmacists to patients allows for the opportunity to provide influential immunization outreach. With the Advisory Committee on Immunization Practices approving the release of revised immunization schedules annually, pharmacists' approach for screening patient eligibility for immunizations remains ever changing, establishing potential demand for reinforcing education of recommendations. This project assessed whether retail pharmacists had greater knowledge and confidence about the Center for Disease Control and Prevention (CDC) recommendations on pneumococcal vaccination administration in adults following academic detailing.

Methods: A pharmacy student was trained by a retail pharmacist to independently lead academic detailing sessions based on a two page pneumococcal vaccination pathway assembled by the Drug Information Services at the University of Rhode Island to highlight the appropriate screening process for eligible patients. Detailing at local pharmacies was scheduled cognizant to workflow and lasted a maximum of ten minutes. At the conclusion of each session a copy of the vaccination pathway was given to the pharmacists as an in store reference guide. A self-administered pre-survey was given immediately following detailing in closed answer format using the following scale: SA=Strongly Agree, A=Agree, N=Neutral, D=Disagree and SD= Strongly Disagree to assess pharmacists' expectations on how student led academic detailing would impact pharmacist knowledge and confidence on screening patients based on the recommended changes to pneumococcal vaccines in adults. All responses were anonymous and eligible subjects were able to decline participation. An open response section was provided for feedback on how to improve detailing sessions or the educational material provided. Three months later, a telephonic post-survey to measure how pharmacist applied academic detailing into their vaccination practices assessed if administration of pneumococcal vaccinations increased.

Results: Five pharmacists completed the IRB approved pre and post survey. The pre-survey demonstrated immediately following academic detailing, majority of pharmacists (80%) indicated they agreed baseline knowledge of identifying patients requiring pneumococcal vaccinations improved, with 20% of pharmacists indicating they strongly agreed. All pharmacists strongly agreed the two-page pneumococcal vaccination pathway was easy to understand and all strongly agreed with applying the vaccination pathway in practice. In regard to influencing vaccination practices after detailing, 20% indicated neutral expectations of change, 20% indicated they agreed with expecting change and 60% indicated they strongly agreed with expecting change. The post-survey demonstrated 80% agreed that they administered more pneumococcal vaccinations as a result of academic detailing, with 20% disagreeing with observing changes in their vaccination practice. All pharmacists indicated that they were more confident after one-on-one educational academic detailing and that they would benefit from academic detailing in the future about major immunization updates.

Conclusion: Student led academic detailing on a major vaccination update helped to identify a demand among pharmacists to receive periodic one-on-one clinical outreach on major changes in vaccination practice to enhance pharmacist knowledge and confidence in retail pharmacy.

Submission Type: Evaluative Study

Session-Board Number: 2-324

Poster Title: Prescriber adherence to documentation of indication and duration of antimicrobials in a community teaching hospital

Primary Author: Ethan Melillo, University of Rhode Island, Rhode Island; **Email:** ethanmelillo@my.uri.edu

Additional Author (s):
Monica Dorobisz
Jayne Pawasauskas

Purpose: Several government organizations have proposed regulations that require hospitals to implement an antimicrobial stewardship program (ASP). The CDC has published seven ASP core elements providing detailed examples of actions to support optimal antibiotic use and the need to track outcomes such as adherence to documentation of indication and anticipated duration. The purpose of the study is to determine if a specific indication and anticipated duration of therapy is documented, either at order entry or in the medical record, for any patient receiving an antimicrobial agent during their stay in order to assess compliance and identify ways to improve documentation.

Methods: The institutional review board approved this observational retrospective chart review at a 359 bed community teaching hospital. Patients over the age of 18 years were included if they spent at least one consecutive night in an inpatient unit between May 1, 2016 and June 30, 2016 and were prescribed an antimicrobial during their stay. Patients admitted only to the emergency department were excluded, as were surgical patients without electronic surgical antibiotic prophylaxis orders. Patients were identified from an electronic report generating all antimicrobial orders during the study period, and five patients per antimicrobial were randomly selected to a final sample size of 250 patients. Data collection included the prescriber type (eg. hospitalist, surgeon, etc.) in order to assess trends, whether or not the indication and anticipated duration was documented, and details regarding the location of documentation, whether or not an indication was empiric, definitive based on culture results, or prophylactic, and whether the actual antimicrobial duration was shorter, longer, or the same as the documented anticipated duration. Any recommendation left by a pharmacist regarding

antimicrobials was also captured. The primary outcomes were the percent of patients who were prescribed an antimicrobial with a documented 1.) indication and 2.) anticipated duration.

Results: An indication was documented in 81% of patients. Of those with documentation, 62% were recorded either in the admission note or day one progress note; however, 7% were not documented until later in the stay or the discharge summary. The majority of indications were empiric (74%), followed by definitive (16%) and prophylactic (10%). The providers who prescribed the majority of antimicrobials had high rates of indication documentation (hospitalists 88%; infectious disease 96%; residents 87%), while surgeons had the lowest rate (27%). An anticipated duration was documented in 44% of patients. Of those with documentation, 77% were either ordered with a stop date/single dose or documented in the admission note/day one progress note. The most common anticipated durations documented were "until culture results" (16%), seven days (14%) and five days (8%); 63% of the time, the actual duration was the same as anticipated (19% shorter and 14% longer than anticipated). Anticipated duration documentation was inconsistent among common prescribers (hospitalists 33%; infectious disease 57%; residents 48%) and primary care providers had one of the lowest rates of documentation (18%). Twenty-five percent of patients had a pharmacist intervention, and the indication or duration were mentioned in 10% and 8% of patients, respectively.

Conclusion: Antimicrobial indications are documented frequently but not always in an ideal location, while anticipated durations are documented in less than half of patients. This data supports the creation of mandatory fields during computerized prescriber order entry to provide a single place where this information can be accessed. Improved documentation will enhance the ability of the ASP to determine if antimicrobials are appropriate and aid in the process of discharge planning. This baseline adherence data identifies an issue where the ASP can implement policies and interventions and track improvement as an ASP outcome measure.

Poster Title: Evaluation of free clinic adherence with the joint national committee 8 (JNC 8) guidelines

Primary Author: Tolani Olagundoye, University Of Rhode Island, Rhode Island; **Email:** tolagundoye@my.uri.edu

Additional Author (s):
Anne De Groot
Valerie Joseph Almeida-Monroe

Purpose: According to the Centers for Disease Control, about 75 million Americans are affected by high blood pressure. Additionally, statistics show that about 28.6 million Americans are uninsured. Many uninsured patients seek treatment from emergency departments, community health centers, or free clinics in their area. The Joint National Committee 8 (JNC 8) defined evidence-based guidelines for the treatment of hypertension in 2014. The purpose of this project was to determine whether uninsured patients with hypertension at a local free clinic were receiving evidence-based treatment for hypertension and whether patients attained generally accepted goal blood pressure targets.

Methods: Performing a retrospective chart review to compare current treatment of Clinica Esperanza/Hope Clinic (CEHC) patients to the JNC 8 evidence-based guidelines. Patients between the age of 29 to 78 years with hypertension with or without diabetes were identified using ICD-10 diagnosis codes for hypertension (I10) and type 2-diabetes (E11). Data collection included gender, race, blood pressure readings from the two latest clinic visits, information about chronic kidney disease, age and antihypertensive medication. Patients meeting the inclusion criteria and receiving care for hypertension and type 2 diabetes between January 1, 2015 to September 1, 2016 were evaluated. A patient age 60 or greater is considered to be at blood pressure goal if they had an average of two systolic blood pressure readings of less than 150 and diastolic blood pressure of less than 90. Patients aged 60 or less, any race, with or without type 2 diabetes was considered to be at blood pressure goal if the average of two systolic blood pressure readings was less than 140 and diastolic blood pressure of less than 90.

Results: A total of 68 patients with a primary diagnosis of hypertension or hypertension with diabetes and with a mean age of 55.8 ± 11.99 years were identified in this retrospective chart review. Demographically, 46 percent of the hypertensive patients were women, 85 percent were Latino, and 15 percent were African American, African or Haitian. Overall, 79 percent (54/68) of patients at this free clinic were at blood pressure goal and 95 percent (41/43) were prescribed the correct medications. Of the 58 Latino patients, twenty-two Latino/Hispanic patients did not receive drug therapy because they were at blood pressure goal without requiring medication. The remaining uninsured Latino patients (n=36) with hypertension with or without diabetes or chronic kidney disease were given recommended treatment and 84 percent (49/58) met JNC8 recommended blood pressure goals. Of the 10 uninsured African American, African and Haitian patients, 9 were prescribed evidence-based antihypertensive treatment (two patients required no drug therapy because their blood pressure was at goal) while 1 received no drug therapy despite slightly elevated blood pressure. Five of the African American, African and Haitian patients were at goal blood pressure (62 percent).

Conclusion: This retrospective chart review of hypertensive patient care at a local free clinic demonstrated that the majority of hypertensive patients were receiving evidence-based treatment for hypertension and had attained blood pressure targets defined by the JNC 8 guidelines.

Poster Title: Assessing students' use and knowledge of common pain relievers

Primary Author: Gina Villano, University of Rhode Island, Rhode Island; **Email:** villanog@my.uri.edu

Additional Author (s):
Thomas Szymanski
Lisa Cohen

Purpose: Recently, there has been concern with over-the-counter (OTC) analgesics, especially acetaminophen, which is a common cause of overdose and hepatotoxicity. Currently, there is limited research on the use of analgesics in the college-age population. The goal of this study was to assess students' use and knowledge of common OTC analgesics.

Methods: We conducted this assessment using a brief, one-time paper survey given to students at the University of Rhode Island (URI). Upon informed consent, students completed the survey at random locations across campus including residence halls, dining halls, and student organizational meetings. This survey was approved by the URI Institutional Review Board.
The survey asked students to identify the uses for OTC analgesics from a checklist of common, treatable conditions. To assess knowledge of analgesics, students were asked to identify which drugs were nonsteroidal anti-inflammatory drugs (NSAID) from a list of OTC analgesics. Students were also asked about the duration of analgesic use, whether they read the drug facts panel, if they exceeded the maximum daily dosage, if they took the medication around the clock or as needed, if they were aware of the risks of the medications, if they received help when choosing the medication, and if they drank alcoholic beverages.

Results: A total of 126 students took part in the survey. Of those surveyed, 55.4 percent were in their freshman year of college and 67.8 percent were female. Those who consumed alcohol were more likely to exceed the maximum daily dose than those who did not report drinking alcohol (p equals 0.002). Fourteen percent of respondents were able to score a 6 out of 8 possible points in correctly identifying NSAIDs, while those achieving a score of 4 out of 8 and 5 out of 8 were 20 percent and 22 percent, respectively. In addition, the difference in knowledge

between health majors and non-health majors on NSAID knowledge was not significant (p equals 0.672). Eighty percent of students reported using a pain reliever for less than seven consecutive days, while 20 percent reported taking it for greater than a week. Fifty percent of participants reported frequently or always reading the instructions on the package of the medication. Of those that read the directions, 21 percent have exceeded the maximum daily dosage. Seventy percent of respondents claimed to be aware of the risks of taking analgesics. Only 12.4 percent received help when choosing their medication at the pharmacy.

Conclusion: The results of this study highlight the need to educate consumers about the proper use of NSAIDs. Pharmacists are the most accessible healthcare professional and have the opportunity to help with appropriate and safe use of OTC analgesics.

Poster Title: Characterizing the Use of Procalcitonin Concentrations to Inform Antibiotic Therapy at a Community Hospital

Primary Author: Nicholas Boemio, University of Rhode Island, Rhode Island; **Email:** nicholas_boemio@my.uri.edu

Additional Author (s):
Donald Allegra
Valerie Anselmo

Purpose: Procalcitonin (PCT) has become an important marker in the diagnosis of and treatment direction for sepsis and lower respiratory tract infections (LRTI). The development of PCT-guided treatment algorithms allows clinicians to discontinue antibiotic therapy earlier or avoid antibiotic therapy altogether, in qualifying patients, without detrimentally affecting outcomes. The goal of this project was to optimize clinician ordering of PCT concentrations and subsequent appropriate antibiotic therapy based on PCT-guided treatment algorithms at Hackettstown Medical Center (HMC) in Hackettstown, New Jersey.

Methods: A retrospective analysis included patients with at least one PCT result during a one-month period from June 1 to June 30, 2016. Data was abstracted from included cases and information regarding indication for antibiotic treatment, antibiotics given, length of stay, PCT results, and appropriate use of PCT-guided treatment algorithms were obtained and analyzed. The retrospective analysis used an evidence-based PCT-guided treatment algorithm produced by Nebraska Medicine's Antibiotic Stewardship Program. Accurate use of the PCT-guided algorithm was based strictly on PCT thresholds and indications for follow-up PCT monitoring recommended in the algorithm.

Results: Sixty-nine patient cases were identified as having at least one PCT result and were included for further analysis. Ninety-six PCT tests were ordered, an average of 1.42 ± 0.7 tests per patient. Forty-four patients (63.8%) had PCT tests ordered for the evidence-based indications of sepsis and LRTI. Twenty-two patients (34.8%) did not have appropriate PCT follow-up based on the treatment algorithm. Among those, 18 did not receive follow-up when it was indicated and six received follow-up when it was not. Antibiotic therapy was changed

appropriately, based on the PCT treatment algorithm, in only 22 patients (31.9%). Upon completion of the analysis, it was determined that further education was needed to optimize use of the evidence-based PCT-guided algorithm, thereby improving use of PCT concentrations and appropriate antibiotic therapy.

Conclusion: Retrospective analysis was helpful in establishing a baseline for use of PCT concentrations to guide antibiotic prescribing. Follow-up PCT testing for patients with initially high PCT levels and appropriate avoidance or discontinuation of antibiotic therapy based on the PCT-guided algorithm were determined as the two areas requiring improvement. Education targeted at optimizing both areas was provided to HRMC physicians in a memo by the head of Infectious Diseases. Follow-up to determine the effectiveness of educational activities will be conducted in December 2016.

Poster Title: Vancomycin dose adjustments based on incorrectly drawn trough levels: A role for antimicrobial stewardship and education

Primary Author: Emily Bodo, University of Rhode Island, Rhode Island; **Email:** emily_bodo@my.uri.edu

Additional Author (s):
Rosette Chhor
Tristan Timbrook
Kerry LaPlante
Megan Luther

Purpose: Vancomycin is commonly prescribed to hospitalized patients and frequently a target for antimicrobial stewardship programs. Vancomycin trough levels are obtained during therapy to assess whether dosing is therapeutic, and to avoid toxicity based on clearance of the drug. Appropriately drawn troughs require at least 3 doses administered to reach steady-state, within 30 minutes of the next dose, and at the correct interval from the preceding dose. Incorrectly drawn troughs and subsequent dose adjustments can lead to negative patient outcomes. Our objective was to assess the appropriateness of vancomycin dosing and monitoring within the Providence Veterans Affairs Medical Center (VAMC).

Methods: Two pharmacy students and a pharmacy research fellow performed a retrospective chart review to evaluate the use of vancomycin. This study was performed as part of the antimicrobial stewardship program, with Institutional Review Board approval and waiver of informed consent. Patients were randomly selected to achieve a sample size of 50 from all intravenous vancomycin orders between January 1, 2015 and December 31st 2015 at the Providence VAMC. Patients were excluded if vancomycin treatment was < 48h, if they were < 18 years old, or if the vancomycin was being taken orally. Electronic medical records were searched for baseline demographics including age, gender, race, height, weight, and baseline serum creatinine. The Providence VAMC provides our clinicians with guidelines on vancomycin dosing in adult patients, including a validated dosing nomogram. We assessed whether the initial vancomycin order matched the nomogram recommendations. Data was also collected on vancomycin dosing, trough monitoring, dose adjustments, vancomycin days of therapy, and

serum creatinine changes. Descriptive statistics including means, standard deviations, and percentages were used to describe the data.

Results: There were 411 unique patients at our institution who received intravenous vancomycin in 2015 and we reviewed 89 charts to include 50 patients. Our chart review revealed that patients were generally white (92%) males (92%), with a mean age of 71.0 +/- 14.3 years. Baseline serum creatinine was 1.1 +/- 0.5 mg/dL, with an estimated creatinine clearance of 68 +/- 30 mL/min (per Cockcroft Gault). Vancomycin was administered for a mean of 4.2 +/- 1.8 days during the admission. Initial doses followed our dosing nomogram in 44% of patients. In patients dosed at 1 gram Q12H (n=19), only 52.6% (n=10) were appropriate based on the nomogram. Forty (80%) patients had at least one vancomycin trough drawn, with an average of 1.9 +/- 0.8 troughs drawn. The initial trough was drawn on average day 2.4 +/- 1.0 of therapy. However, 65% (n=26) of the initial troughs were drawn inappropriately. Following the initial trough, 21 regimens were adjusted. Of those, 66.7% (n=14) were adjusted based on inappropriately drawn troughs. Nine (18%) patients experienced an increase in serum creatinine of 0.5mg/dL or greater during vancomycin therapy, indicating acute kidney injury according to the Risk, Injury, Failure, Loss, and End-stage kidney disease criteria.

Conclusion: This study demonstrates the importance of appropriate vancomycin dosing and monitoring. Correctly drawn troughs can be a useful tool in evaluating vancomycin therapy. At our institution, however, there is a high percentage of incorrectly drawn troughs, with subsequent dose adjustments. There is an opportunity for staff education (nursing, pharmacy, medicine) on appropriate vancomycin dosing and trough timing to assist in antimicrobial stewardship and medication safety at our facility. Future studies should assess the impact of provider education on vancomycin appropriateness and patient outcomes.

Poster Title: Efficacy and cost effectiveness of proprotein convertase subtilisin/kexin type 9 (PCSK9) inhibitors in familial hypercholesterolemia: a systematic review

Primary Author: Alysa Redlich, University of Rhode Island, Rhode Island; **Email:** aredlich1@gmail.com

Additional Author (s):
Kristina Ward

Purpose: Two proprotein convertase subtilisin/kexin type 9 (PCSK9) inhibitors, evolocumab and alirocumab, are approved for familial hypercholesterolemia (FH) disorders. In patients with FH, conventional lipid lowering therapies are often unsuccessful in reducing low-density lipoprotein cholesterol (LDL-C), cardiovascular risk, and mortality. Priced significantly higher than traditional cholesterol lowering medications, PCSK9 inhibitors have the potential to pose a significant financial burden on the US health care system. The objective of this project was to evaluate the evidence for PCSK9 inhibitor use in patients with FH disorders and classify its relative cost effectiveness for payers.

Methods: A systematic search of the PubMed and EMBASE databases was conducted to identify clinical trials specifically enrolling patients with either homozygous or heterozygous FH. Each trial was evaluated for quality, reliability, and internal validity by two independent reviewers based on the Jadad scale. Differences in scoring were resolved through discussion between the two reviewers. A Jadad score for inclusion of three or greater was set prior to beginning evaluation. Six trials received a Jadad score of greater than three and were included in the analysis. Key attributes such as sample size, inclusion criteria, exclusion criteria, interventions, study duration, and results of each trial were tabulated for comparison. Specifically, the calculated LDL-C mean change from baseline at week 12 or 24 was analyzed for each trial based on the desired primary endpoint. Other lipid parameters including HDL-C and fasting triglycerides were assessed secondarily when available. Additionally, reported adverse events from each trial were tracked and organized by drug to assess safety. Value-based pricing benchmarks and cost effectiveness data were obtained from the PCSK9 Inhibitors for Treatment of High Cholesterol draft report produced by the Institute for Clinical and Economic

Review. These measures were specifically applied to the FH patient population to assess budget impact and costs based on estimated reductions in adverse events.

Results: Efficacy data from each trial was assessed based on the calculated LDL-C mean change from baseline. Early PCSK9 inhibitor trials do not present cardiovascular outcomes data, which poses a problem for assessing true efficacy of the agents. RUTHERFORD-2 (Raal et al) demonstrated the largest percent reduction in LDL-C from baseline in patients with heterozygous FH receiving evolocumab 140mg every two weeks. Measured at week twelve, LDL-C decreased by 61.3% from baseline in treatment arm patients compared to an increase of 2.0% in patients receiving placebo. The smallest reductions in LDL-C seen in treatment arm patients were noted in TELSLA Part B (Raal et al). TELSA Part B only enrolled patients with homozygous FH, netting reductions in LDL-C of 23.1% with evolocumab 420mg administered every four weeks compared to a 7.9% LDL-C increase in placebo recipients. PCSK9 inhibitors come at an estimated cost of $14,600 per person for one year of treatment. In patients with FH, assuming approximately 75% of patients receive treatment over the course of five years, PCSK9 inhibitors will attribute $19 billion in spending to the health care system (Tice et al).

Conclusion: Efficacy data currently available for PCSK9 inhibitors in the FH population focuses solely on LDL-C reductions. While reductions in LDL-C are important in achieving lower total cholesterol levels, cardiovascular impact is difficult to determine. Longer-term trials must be conducted in order to ensure LDL-C reduction translates to reductions in cardiovascular risk events and mortality. At their current market price, PCSK9 inhibitors are not considered to be an affordable intervention. Payers would require significant price reductions or substantial outcomes data to offset quality adjusted life year parameters in order to justify the expense.

Submission Type: Evaluative Study

Session-Board Number: 2-330

Poster Title: Changes in antimicrobial use and resistance rates pre- and post-implementation of an antibacterial stewardship program

Primary Author: Spencer Donovan, University of Rhode Island - College of Pharmacy, Rhode Island; **Email:** spencer_donovan@my.uri.edu

Additional Author (s):
Haley Morrill
Kerry LaPlante

Purpose: Antimicrobial stewardship programs have the potential to reduce antibiotic use and slow the development of resistance in various pathogens. This can be beneficial to both patients and institutions by avoiding costly treatment complications such as Clostridium difficile infection and extended hospital stays. The purpose of this study was to evaluate the changes in antibiotic use and pathogen resistance rates following the implementation of an antibacterial stewardship program.

Methods: An antimicrobial stewardship program (ASP) which utilized prospective audit and feedback was formally implemented at the VA Medical Center in Providence, RI in September 2012. The Providence VA Medical Center is a small teaching hospital licensed for 119 beds. Using the CDC's National Healthcare Safety Network (NHSN) Antimicrobial Use and Resistance options, we retrospectively analyzed antibiotic use using days of therapy per 1000 patient days pre- and post-implementation of this program. Resistance rates in pathogens were also evaluated.

Results: We evaluated antibiotic use and resistance rates from 2008 to 2015. Resistance rates were consistently high prior to implementation of the ASP in 2012. Post-implementation of the ASP antibiotic use decreased for several agents (amoxicillin/clavulanate, azithromycin, cefotaxime, cefoxitin, cephalexin, ciprofloxacin, linezolid, metronidazole, moxifloxacin, trimethoprim/sulfamethoxazole) and pathogen resistance rates also decreased from 2012 to 2015 for Pseudomonas aeruginosa treated with imipenem (5%) and cefepime (5%).

Conclusion: Post-implementation of the ASP, resistance rates of many pathogens remained similar to rates pre-implementation. Total antibiotic use decreased for most antibiotics post-implementation of the ASP. Antimicrobial stewardship programs are important for reducing antibiotic use and limiting the propagation of antimicrobial resistance.

Poster Title: Rates of correct inhaler technique in high-risk, community-dwelling older adults with chronic obstructive pulmonary disease (COPD)

Primary Author: Tamara Bystrak, University of Rhode Island College of Pharmacy, Rhode Island; **Email:** tamara@salixllc.com

Additional Author (s):
Christine Eisenhower

Purpose: Patients with chronic obstructive pulmonary disease (COPD) are often managed with multiple inhaler devices. There are several different devices available, with unique steps that can make correct administration challenging. Older adults may have a higher risk of misusing inhalers due to cognitive and functional limitations. Improper technique can lead to poor disease control, greater rates of hospitalization, and reduced quality of life. The purpose of this study was to determine the ability of older adults to appropriately self-administer three common inhaler devices.

Methods: This study was a retrospective chart review of older adults enrolled in the Program of All-inclusive Care for the Elderly of Rhode Island (PACE-RI). Participants were included if they had an International Classification of Disease Ninth or Tenth Edition (ICD-9 or ICD-10) diagnostic code related to COPD, lived in the community, self-administered inhalers, and were evaluated by a clinical pharmacist between January and August 2016. The three devices evaluated were the metered dose inhaler (MDI), the trademarked Diskus, and the trademarked HandiHaler. The clinical pharmacist used standardized lists of inhaler steps to categorize participant technique as correct or incorrect. Lists were generated for each device based on the instructions for use in the prescribing information. Technique was incorrect if one or more steps were performed incorrectly, forgotten, or required assistance to complete. The primary endpoint was the overall rate of correct inhaler technique among older adults with COPD. Secondary endpoints included rates of correct technique for each of the three devices, a comparison of the two dry powder inhalers (DPIs), and an analysis of problematic inhaler steps. Each individual inhaler step was further classified as "universal" across all devices, or as an "inhaler-specific" step.

Results: A total of 42 encounters from 20 participants were included. N equals 21 encounters were evaluations of the MDI, n equals 13 were evaluations of the Diskus, and n equals 8 were evaluations of the Handihaler. Participants were between the ages of 58 and 80 years old, with a mean age of 68 years old. The majority of participants were female (65 percent).

The overall rate of correct inhaler use was 66.7 percent (28/42). Of the three devices, the lowest rate of correct technique (57.1 percent or 12/21) was demonstrated with the MDI. The most common reason for MDI technique failure was forgetting to shake the canister before use. Shaking before use was considered an inhaler-specific step.

In regards to the two DPIs, correct inhaler technique was demonstrated 69.2 percent of the time with the Diskus and 87.5 percent of the time with the HandiHaler. The most common mistakes observed with the Diskus were not properly clicking the lever and not rinsing mouth after use. Only one participant using the HandiHaler failed due to difficulty adding the capsule to the container.

Conclusion: Results indicate that one in every three inhaler administrations in high-risk older adults with COPD could be compromised due to improper inhaler technique. Improper technique was observed most often for participants using an MDI, despite the low number of additional, inhaler-specific steps. Identifying the high rate of misuse of MDIs (42.9 percent) should encourage providers to counsel on the importance of shaking the inhaler. Results also suggest that the HandiHaler may be easier for older adults with COPD to use compared to the Diskus.

Poster Title: Multidisciplinary ambulatory intravenous diuretic clinic improves short-term mortality and rehospitalizations in veterans with decompensated heart failure

Primary Author: Amy St. Amand, University of Rhode Island College of Pharmacy, Rhode Island; **Email:** amy_stamand@my.uri.edu

Additional Author (s):
Kaitlin Murphy

Purpose: Multidisciplinary ambulatory intravenous diuretic clinics for volume management in patients with heart failure have been found to be safe and effective at promoting significant urine output. This strategy may provide an alternative to hospitalization for the management of selected heart failure patients. Data on the effectiveness of this strategy to prevent rehospitalization and mortality are limited. Therefore, the primary objective of this research is to evaluate the effectiveness of an outpatient multidisciplinary intravenous diuretic clinic versus standard observational hospitalizations of less than 48 hours for decompensated heart failure on the time to rehospitalization or death.

Methods: We conducted a retrospective cohort study of patients with heart failure (n equals 88) at the Providence Veterans Affairs Medical Center. Patients were included in the analyses if they received at least one multidisciplinary ambulatory intravenous diuretic clinic visit or an observational hospitalization of less than 48 hours for decompensated heart failure between January 1, 2014 and June 30, 2016. Patients were referred to the multidisciplinary outpatient diuretic clinic based on clinical judgment of the cardiology staff and treated according to a pre-established protocol and treatment algorithm. Patients were followed from their index event, defined as the date of first intravenous diuretic clinic visit or date of first observational hospitalization for heart failure, until death or end of study. Using both unadjusted and adjusted Cox proportional hazards modeling, we compared the time to any hospitalization or death between the multidisciplinary intravenous clinic and the observational hospitalization cohort over 180 days of follow-up. The time to heart failure hospitalization or death was also compared between the two intervention arms. Sensitivity analyses were also conducted to determine the impact of hospice enrollment and palliative care on the study interventions. Our

study was approved by the Providence Veterans Affairs Medical Center Institutional Review Board and conducted in accordance with the Declaration of Helsinki.

Results: In the ambulatory diuretic clinic group, 27 patients (mean age 78.4, plus or minus 8.18 years) were treated over a median of 3 visits per patient (range of 1-84 visits per patient). In the comparison group, 61 patients (mean age 80.9, plus or minus 11.38 years) were hospitalized for observation. Patients in the ambulatory diuretic clinic had a higher body mass index (32.1 plus or minus 7.87 versus 28.5 plus or minus 5.79 kilograms per meter squared, p equals 0.02); and more comorbidities including: chronic obstructive pulmonary disease (55.6 versus 27.9 percent, p equals 0.01), pulmonary hypertension (29.6 versus 11.5 percent, p equals 0.04), and obstructive sleep apnea (59.3 versus 24.6 percent, p less than 0.01). Adjusting for age and imbalances in baseline characteristics, the hazards of any hospitalization or death (adjusted hazard ratio 0.29, standard deviation 0.14, 95 percent confidence interval 0.11 to 0.76, p equals 0.01) and heart failure hospitalization or death (adjusted hazard ratio 0.30, standard deviation 0.20, 95 percent confidence interval 0.08 to 1.13, p equals 0.08) were reduced for patients in the multidisciplinary ambulatory diuretic clinic versus those in the hospitalization cohort. Sensitivity analyses for hospice enrollment and palliative care did not change our findings.

Conclusion: In veterans with decompensated heart failure, a multidisciplinary ambulatory intravenous diuretic clinic was protective against any readmission or death over 180 days of follow up when compared to a strategy of observational hospitalization for less than 48 hours. Future research should prospectively analyze outpatient intravenous therapy in a larger and more diverse population.

Poster Title: Prescriber adherence and pharmacist interventions when adding blood pressure parameters on inpatient orders of antihypertensive medications

Primary Author: Julie Kelly, University of Rhode Island College of Pharmacy, Rhode Island;
Email: julie_kelly@my.uri.edu

Additional Author (s):
Marco DelBove

Purpose: At a 294-bed community hospital, a medication event occurred where a patient received doses of three antihypertensive medications, became hypotensive, and was admitted to the intensive care unit. Medication use policy was then revised to require holding parameters on all antihypertensive medications. A department wide email and educational sessions to all pharmacists highlighting a mandate for intervention on all orders without holding parameters was sent in May 2016. The purpose of this study is to determine if prescribers and pharmacists are compliant with this policy and if the department wide education made an improvement on overall compliance to this policy.

Methods: A retrospective chart review was conducted using electronic medication records to identify if the prescriber included blood pressure holding parameters, and whether a pharmacist intervention was implemented. A randomized sample of all patients admitted to the hospital with antihypertensive medications was included via a computer-generated list. A total of 406 medication orders were reviewed, 174 of which were between April 1, 2016 and May 2, 2016 (before the department wide communication) and 232 orders were between August 1, 2016 and August 31, 2016 (after the department wide communication). The primary outcomes were the percent of orders including blood pressure parameters and the percent of orders with an intervention from the pharmacist to the prescriber to add blood pressure parameters.

Results: Of all 406 antihypertensive orders reviewed, 33.25% included blood pressure parameters, of which 47.4% required a pharmacist intervention. Of the 66.75% of orders without blood pressure parameters in the total sample, 23.25% had a pharmacist intervention to include parameters however there was no prescriber follow up. Of the 174 orders reviewed in April, 16.67% had blood pressure parameters, 37.0% of which required a pharmacist

intervention. Of the 83.33% that did not contain blood pressure parameters from the April sample, 20.0% included interventions from the pharmacist yet there was no follow up by the prescriber. Of the 232 orders reviewed in August, 45.7% had holding parameters, of which 50% required an intervention from the pharmacist. Of the 54.31% of orders reviewed that did not include parameters from the August sample, 26.98% had a pharmacist intervention with no prescriber follow up. Overall, there was a 12.45% increase in blood pressure holding parameter inclusion after the implementation of the revised medication use policy.

Conclusion: Medication events leading to hypotension are a major cause of complications and extended stay amongst hospitalized patients. This data displays a need for better compliance to including blood pressure holding parameters among prescribers and pharmacists to ensure patients are not receiving antihypertensive medications inappropriately. This data also shows that department wide communications via email and educational session are effective in improving pharmacist compliance to updated hospital policies. Possible solutions to further improve compliance include allowing pharmacists to add blood pressure parameters on antihypertensive medication orders, or building blood pressure holding parameters into electronic medication order sets.

Poster Title: Causative factors contributing to clinical inertia at a family medicine clinic

Primary Author: Brittany Durgin, University of Rhode Island College of Pharmacy, Rhode Island;
Email: brittany_durgin@my.uri.edu

Additional Author (s):
Kirsten Bruell
Corinn Martineau
Jamie Sommer

Purpose: Clinical inertia – defined as the lack of appropriate therapy intensification when indicated – is a well-known impediment to appropriate patient treatment, especially in patients with type 2 diabetes. National trends suggest that diabetes treatment regimens are only properly modified 39 percent of the time, and the odds of achieving target hemoglobin A1C (A1C) goals are five times lower when treatment is not properly modified. Further investigation into causes of clinical inertia at a family medicine clinic may help illuminate causative factors, and more precisely identify where intervention strategies should be focused.

Methods: Retrospective review of electronic medical records of patients with type 2 diabetes presenting to a family medicine clinic was conducted to determine: if clinical inertia was present, its associated causative factors, and if the course of action following the appointment was concordant with the 2015 American Diabetes Association (ADA) diabetes management guidelines. Guideline concordance was defined as the increase in dose or addition of a new antihyperglycemic medication in response to an A1C value greater than or equal to 7 percent in the general population, or an A1C value greater than or equal to 8 percent in patients with extensive comorbidities or at high risk for hypoglycemia. True non-concordance, and thus true clinical inertia, was defined as the unjustified lack of guideline concordance. If there was a justifiable reason for non-concordance (i.e., factors outside the providers' control), that case was not considered to be one of true clinical inertia. Patient A1C levels were recorded at baseline and at seven months to determine if there was any difference. This study included patients 18 years or older with type 2 diabetes whose A1C was greater than or equal to 7 percent. Patients were excluded if they were more than 75 years of age, had type 1 diabetes, were pregnant, or had fewer than two A1C readings within the study window.

Results: A total of 62 patients were included in the study. Clinical inertia was initially found to be present in 60 percent of cases (n equals 37) within the study window, while guideline concordance (without clinical inertia) occurred in 40 percent of cases (n equals 25). Reasons contributing to clinical inertia were subsequently explored, including: other primary problems (e.g., active infection, cancer, or pain) taking precedence during the appointment (8 percent of total, n equals 5), patient unavailability for follow-up during the study window (5 percent of total, n equals 3), and patient refusal of recommended therapy modification (5 percent of total, n equals 3). These cases were considered to be outside of the providers' control, and not true cases of clinical inertia. True clinical inertia, with no discernible justification, occurred 42 percent of the time (n equals 25). The clinical inertia group experienced a decrease in mean A1C from a baseline of 8.4 percent (standard deviation plus or minus 1.20) to 8.3 percent (plus or minus 1.23), whereas the group without clinical inertia experienced a decrease in mean A1C from a baseline of 8.8 percent (plus or minus 1.00) to 8.4 percent (plus or minus 1.41).

Conclusion: Cases without clinical inertia experienced a decrease in A1C levels, whereas the A1C levels of cases with clinical inertia remained approximately the same. After accounting for causative factors, true instances of clinical inertia were 18 percent less frequent than initially observed, but still occurred almost half of the time. Patient educational interventions may further decrease the rates of clinical inertia. Additional study is required to determine the effectiveness of educational interventions, if causative factors of clinical inertia differ in other clinical settings, and if other types of interventions are necessary.

Poster Title: Evaluation of urinalysis, urine culture, and antibiotic utilization in two community, teaching hospitals

Primary Author: Amanda Ryle, University of Rhode Island College of Pharmacy, Rhode Island;
Email: amanda_ryle@my.uri.edu

Additional Author (s):
Kristen McSweeney
Lou Ann Bruno-Murtha
Amanda Barner

Purpose: According to the Centers for Disease Control and Prevention, 20-70% of antibiotics prescribed in hospitals are inappropriate. Asymptomatic bacteriruia is frequently mistreated with antibiotics. Cambridge Health Alliance (CHA), a system of two community, teaching hospitals has had an active Antimicrobial Stewardship Team (AST) since 2007.The goal of the AST is to improve clinical outcomes and minimize cost and unintended consequences associated with antimicrobials, including toxicity and selection of resistant organisms. The purpose of this quality improvement project was to evaluate practices at CHA surrounding urinalysis (UA), urine, culture (UC), and antibiotic utilization in order to identify opportunities for stewardship intervention.

Methods: The CHA Institutional Review Board did not require review of this quality improvement project. All urinalyses from 7/12/16-7/28/16 in patients >18 years admitted to Cambridge or Whidden Hospitals, or seen in emergency departments, were included. Chart review was conducted to determine appropriateness of UC and antibiotic therapy. Data collected included time of UC in relation to UA, organisms, contamination, documented genitourinary symptoms, indication for UC, UA results (leukocyte esterase, nitrates, and white blood cells), diagnosis, presence of catheter, empiric and definitive antibiotic therapy, total duration of therapy, and location. UC was deemed appropriate in pregnant and urologic surgery patients. UC was justified in non-catherized patients with acute dysuria, fever and a genitourinary symptom, 2 genitourinary symptoms without fever, or sepsis without an established source. In patients with indwelling bladder catheters, UC was indicated with fever plus one of the following: neutropenia, post urologic surgery, known obstruction, unexplained

suprapubic/ flank pain, hematuria, delirium, or spinal cord injury with worsening condition. Empiric antibiotics were appropriate if they met ISDA guideline recommendations and ≥85% E. coli susceptibility per CHA's antibiogram. Definitive antibiotics were appropriate if the causative organism was susceptible. Duration was appropriate if total antibiotic days were < 5 for uncomplicated infections (up to 7 days for beta-lactams), and 7-14 days for complicated infections or pyelonephritis. Fluoroquinolones were considered inappropriate for treatment of uncomplicated urinary tract infections.

Results: 99 patients had UA ordered in the 17 day period. Per chart review, the majority of UA orders were justified, however, 4 elderly patients and 3 orthopedic surgery patients had no indications for UA or UC. 75 total patients (75.7%) had a UC and 59 (78.7%) were ordered at the same time as the UA . The UC contamination, positive, and negative culture rates were 42.7%, 28%, and 29.3%, respectively. There were 6 patients with indwelling catheters, 5 were cultured and 4/5 had bacteriuria (80%). Excluding five pregnant and nine urologic surgery patients, 21/61 (34.4%) patients with a negative UA and no urinary symptoms were cultured. Of the 21 cultures, 9 were negative, 9 were contaminated, and 3 had a significant isolate resulting in 69 minutes and $90 of microbiology lab resources wasted in a 17 day period. That equates 24.6 hours and $1,932 annually. Twenty patients were diagnosed and treated for urinary tract infections. Empiric, definitive, and duration of therapy was inappropriate in 10/20 (50%), 6/20 (30%), and 6/20 (30%), respectively. The most common agent selected for inappropriate empiric therapy was ciprofloxacin at 50%. Of note, 29% of E coli are resistant to ciprofloxacin per CHA's inpatient antibiogram.

Conclusion: This review allowed CHA to identify several opportunities to improve diagnosis and treatment of urinary tract infections including: defer UC pending UA review in patients without urinary symptoms (excluding pregnancy and urologic surgery), emphasize better urine collection technique to decrease contamination, avoid routine urine studies in elderly psychiatric patients and pre-op orthopedic patients, and target education to prevent overuse of fluoroquinolones and prolonged antibiotics (>5 days) for treatment of uncomplicated urinary tract infections. As a result of this project, the AST will work with the lab to implement reflux UC based on UA results and deliver education surrounding fluoroquinolone use.

Poster Title: Adherence simulation: an adaptable tool for promoting empathy among student pharmacists

Primary Author: Kelsey Sheehan, University of Rhode Island College of Pharmacy, Rhode Island; **Email:** kels.sheehan@gmail.com

Additional Author (s):
Renee Santo
Erica Estus
Brett Feret

Purpose: The Center for the Advancement of Pharmacy Education (CAPE) 2013 Educational Outcomes emphasize the value of effective approaches to pharmacy practice and patient care. These standards advise pharmacy educators to place importance in the domains of personal and professional development. This project was designed to provide a learning tool for both faculty and preceptors to evaluate and promote self-awareness and empathy in their student pharmacists.

Methods: Student pharmacists in their first professional year at the University of Rhode Island adhered to a complex medication regimen simulated with candy for four weeks during an introductory pharmacy experience. Students were required to fill six prescriptions weekly at a mock pharmacy with limited hours located on campus. They were encouraged to implement personal strategies for remembering to take their prescribed medications. Pre- and post-simulation surveys were administered to determine change in empathy. Surveys consisted of demographic information along with seven questions assessing students' familiarity with adherence complications, level of empathy and understanding of the responsibilities of pharmacists in medication adherence. Each question was rated using a likert scale between one and five (1 - strongly disagree, 5- strongly agree). Students were also required to write a one-page reflection on their experience.

Results: Ninety seven percent (n=29) of students successfully completed both the pre- and post- simulation surveys. The Wilcoxon Signed Rank Test was used to analyze survey data. There was a significant increase in appropriateness of each participant's own empathy in

patient care (p = 0.001) as well as the overall perception of the importance of empathy (p = 0.0007). Student reflections highlighted common barriers faced throughout the four weeks, including limited pharmacy access, difficulty remembering to take medications dosed more than once a day, and medication administration interfering with daily activities.

Conclusion: Simulating a complex medication regimen is associated with increased empathy for patient burdens in the healthcare system. Our results showed a significant improvement specifically in students' perceptions of their own ability to be empathetic in pharmacy practice. This project is easily adaptable and can be implemented in many educational settings to further promote empathy in future health care professionals.

Poster Title: Antimicrobial stewardship in a long-term acute care hospital

Primary Author: Emily McDonnell, University of Rhode Island College of Pharmacy, Rhode Island; **Email:** emily_mcdonnell@my.uri.edu

Additional Author (s):
Anita Jacobson
Michael Poshkus
Erin Scanlon

Purpose: The purpose of this study was to examine the prevalence of antimicrobial use among residents in a long-term acute care hospital, assess the appropriateness of empiric antibiotic choices used to treat genitourinary infections, and provide solutions to enhance the proper use of antibiotics in this population.

Methods: Patient data was collected at a 284 bed long-term acute care hospital by a registered nurse from May 12, 2015 until February 9, 2016. Antibiotic use was recorded daily in various patient care units on a rotating schedule throughout the study period. For each patient that received an antibiotic the indication for use, duration of treatment, cultures ordered, organisms cultured, patient temperature and white blood cell count were recorded if available. Data for each patient was updated daily as lab and susceptibility results became available. At the end of the study period, the data was analyzed to assess specific indications for antibiotic use, commonly cultured organisms, antibiotics prescribed for particular indications, and duration of treatment. The hospital's antibiogram was used to assess resistance patterns and the appropriateness of antimicrobial choices. Results from the study were communicated to the hospital's medical staff at an antimicrobial stewardship meeting. Data related to genitourinary infection rates and prescribing methods were highlighted during the meeting and recommendations for future antibiotic prescribing were discussed.

Results: Between May 12, 2015 and February 9, 2016, a total of 173 orders for antibiotics were recorded. Genitourinary infection was the most common indication for initiating an antibiotic accounting for 22.5% (n=39) of antibiotic orders followed by skin and soft tissue infection, and lower respiratory tract infection. Levofloxacin and sulfamethoxazole/trimethoprim were

frequently prescribed antibiotics for genitourinary infections accounting for 26% (n=10) and 19% (n=7) respectively. The most common organisms that were cultured from the genitourinary tract were Klebsiella pneumoniae and Pseudomonas aeruginosa. According to the hospital antibiogram, Klebsiella pneumoniae isolates were only 58% susceptible to levofloxacin and 60% susceptible to sulfamethoxazole/trimethoprim. Pseudomonas aeruginosa isolates were only 47% susceptible to levofloxacin according to the hospital antibiogram. Escherichia coli and Enterococcus faecalis were also common organisms isolated from the genitourinary tract. Escherichia coli and Enterococcus faecalis isolates were both 100% susceptible to nitrofurantoin according to the hospital antibiogram. Overall, the mean duration of antibiotic treatment for genitourinary infections was 6.5 days.

Conclusion: Due to the low susceptibility of cultured genitourinary isolates, alternative antibiotics may be considered in place of fluoroquinolones for the treatment of genitourinary infections. Based on the hospital antibiogram, nitrofurantoin and sulfamethoxazole/trimethoprim are appropriate oral step-down agents for susceptible infections. Knowledge of patients' recent antibiotic therapy and utilization of the hospital antibiogram are necessary to ensure proper antibiotic selection.

Poster Title: Increasing naloxone distribution through pharmacies to combat opioid epidemic in Rhode Island

Primary Author: Anthony Giuliani, University of Rhode Island College of Pharmacy, Rhode Island; **Email:** agiuliani@my.uri.edu

Additional Author (s):
Celia MacDonnell

Purpose: Increasing naloxone distribution through community pharmacies in Rhode Island can help combat opioid overdose fatalities. Rhode Island ranks seventh highest in the nation for fatal overdose rates per capita with 23.4 deaths per 100,000 people versus the national average of 13.8 per 100,000 recorded in 2014. Educating health care professionals about naloxone and increasing its accessibility can influence the public ultimately helping impede the opioid epidemic. Several initiatives in RI have come forth to promote the distribution and administration of naloxone including the collaborative pharmacy practice agreement for naloxone (CPAN) in 2014 and The Good Samaritan Act established in 2012.

Methods: The data was obtained through the Rhode Island Department of Health to determine the total amount of naloxone dispensed through pharmacies and opioid overdose deaths from 2009 to 2015 in 3-month intervals. The primary focus is based around data from 2014 to 2015, which follows the major naloxone initiatives such as the implementation of CPAN. The data was analyzed to determine if there is an established relationship between the amount of naloxone dispensed by pharmacies and opioid overdose mortality, ultimately determining if this is a feasible approach to combat the opioid epidemic. The data was also assessed to determine a goal for the amount of pharmacy dispensed naloxone to help decrease overdose mortality in RI.

Results: Following CPAN 572 pharmacy based naloxone kits were dispensed between January 2014 and June 2015, representing about a 2-fold increase in community-based distribution of naloxone during 2014. Pharmacies were responsible for 24 percent of all naloxone distributed in RI during that time period. From April to September of 2014 dispensing peaked reaching 235 kits compared to the previous 6 months of 94 kits. During that time overdose deaths decreased by 42 percent (146 to 85). Throughout the next 6 months dispensing decreased by 31% (235 to

164) and overdose deaths increased 56% (85 to 135). From 2014 to the middle of 2015 an inverse relationship was established between pharmacy dispensed naloxone and overdose mortality.

Conclusion: Initiatives supporting naloxone distribution through pharmacies had an impact on decreasing overdose mortality, but distribution must remain high to sustain the mortality reduction. To attain mortality reduction, a pharmacy dispensing goal of 235 naloxone kits over 6 months should be set. Community pharmacies are imbedded within the community and provide easy, convenient access to naloxone kits along with the appropriate education and training. More initiatives are warranted to help increase the amount of naloxone being dispensed through pharmacies to help combat the opioid epidemic in RI.

Poster Title: Traffic lights in a hospital: the pharmacists' role in transitional care rounds

Primary Author: Kyunghye Lee, University of Rhode Island College of Pharmacy, Rhode Island;
Email: kyunghye_lee@my.uri.edu

Additional Author (s):
Mark Rogers
Stephen Cofone

Purpose: The transitional care rounds model in health systems is emerging to enhance the patient discharge process and reduce preventable readmissions. Contrary to traditional multidisciplinary rounds, pharmacist involvement in transitional care rounds has been minimal at non-teaching community hospitals because of time limits. Pharmacists are medication experts and should be allowed to participate in the overall medical care of patients. The purpose of this research was to promote the necessary involvement of pharmacists in transitional care rounds by assessing pharmacist intervention opportunities from medical-surgical units.

Methods: Case management-led transitional care rounds were implemented as a new initiative at a non-teaching community hospital. Color-coded Red/Yellow/Green "traffic lights" were used to communicate patients' discharge probability. During transitional care rounds, the script was limited to specific expectations including hospitalization day number, brief clinical summary, clear clinical endpoint needed for discharge, specific care needs, and barriers to discharge. Pharmacy participation is excluded in this new rounding system, so intervention reports were collected from medical-surgical units to measure pharmacist intervention opportunities. Data from pharmacist intervention reporting was collected over a six-week period, which included three weeks prior to and following the initiation of transitional care rounds. The medical-surgical units included respiratory and telemetry/pediatrics which represented a total of 60 inpatient beds. TheraDoc, a comprehensive surveillance tool, was used to identify clinical intervention opportunities and document pharmacist interventions. The grouping of nine clinical activities included: inappropriate therapy avoided, therapy changes, therapy recommendations, institutional support, IV to PO conversion (antimicrobial), IV to PO conversion (non-microbial), antibiotic stewardship program, high-risk intervention and

recommendation, and vancomycin consults. Each clinical activity was further classified into 32 different sub-categories including (but not limited to) dose adjustments, dosing and drug consultations, duplicate therapy identifications, and new therapy recommendations. The assessment focused on the impact of transitional care rounds on pharmacist opportunities to identify and document clinical interventions prior to and following implementation.

Results: The total number of pharmacist interventions in medical-surgical units was 140 during the three weeks prior to implementation of transitional care rounds. In the respiratory unit, both institutional support and therapy changes accounted for 23 percent of total interventions. In the telemetry/pediatrics unit, institutional support accounted for 31 percent, and therapy changes accounted for 28 percent of the total. Together, these categories comprised nearly half of reported clinical activities. The interventions made in both medical-surgical units showed a similar trend where institutional support and therapy changes were the leading clinical activities amongst interventions reported. After the initiation of transitional care rounds, the overall number of interventions decreased by approximately 16 percent. The clinical activities reported were primarily institutional support and therapy changes; this included 19 percent and 36 percent, respectively, for the respiratory unit, and 26 percent each for the telemetry/pediatrics unit. The limitation of accurately measuring the number of interventions included fluctuation in patient census and inability to identify clinical interventions communicated verbally. The availability of data was insufficient to definitively assess the impact of transitional care rounds on pharmacist interventions. However, the metrics used helped to identify overall negative effects within the first three weeks of implementation.

Conclusion: The newly implemented transitional care rounds limited the role of pharmacists in a non-teaching community hospital. The use of interventional measurements showed the importance of pharmacists' active involvement and illustrated the negative impact that excluding pharmacists in transitional care rounds had on documented pharmacist interventions. In order to work inside this new transitional care rounding model, the pharmacy department will need to develop a systematic approach to achieve effective communication and collaboration with other healthcare providers.

Poster Title: Characterization of early sepsis care at a community teaching hospital prior to the implementation of a sepsis protocol

Primary Author: Emily Dionne, University of Rhode Island College of Pharmacy, Rhode Island; **Email:** emily_dionne@my.uri.edu

Additional Author (s):
Iman Aberra
Monica Dorobisz
Todd Brothers
Michelle Kelley

Purpose: Sepsis remains one of the most expensive and deadliest reasons for hospitalization. In-hospital mortality rates for sepsis are 8 times higher than mortality rates for all other hospitalizations. The Surviving Sepsis Campaign (SSC) has published 3-hour and 6-hour sepsis bundles to improve sepsis care and reduce sepsis-related mortality. In 2015, the Centers for Medicare and Medicaid Services (CMS) adopted these bundles as a new core measure, which prompted sepsis protocol implementation at Kent Hospital. The primary objective of our study is to assess SSC bundle compliance at our facility prior to protocol implementation.

Methods: We conducted a retrospective study to assess SSC bundle compliance. The study was approved by the institutional review board. Electronic health records were reviewed for patients who met severe sepsis or septic shock criteria during their hospital stay and who were discharged during April 2016. Patients were identified using the tenth revision of the international statistical classification of diseases and health related problems (ICD-10) diagnosis codes. Major exclusion criteria included age less than 18 years, documented refusal of care, death within 3 hours of severe sepsis presentation, and death within 6 hours of septic shock presentation. Baseline demographics collected included patient age, gender, weight, admission category, and time of severe sepsis and septic shock presentation. Data was collected for each component of the 3-hour bundle (serum lactate level, blood cultures collected prior to antibiotic administration, administration of broad-spectrum antibiotics, and adequate fluid resuscitation for hypotension or initial serum lactate level greater than 4 millimoles per liter). Data was also collected for each component of the 6-hour bundle (serum lactate level if initial

level was greater than 2 millimoles per liter, initiation of vasopressors for hypotension unresponsive to fluid resuscitation, and volume status reassessment). All data was analyzed using descriptive statistics.

Results: A total of 100 patients were identified using ICD-10 codes. Fifty-five patients met inclusion criteria. Of these patients, 32 (57 percent) were women, 49 (88 percent) met severe sepsis criteria in the emergency department, and the mean age was 70 years. Of the 55 patients, 45 (80 percent) had a lactate level drawn, 40 (71 percent) had blood cultures drawn prior to antibiotic administration, and 50 (93 percent) received broad-spectrum antibiotics within 3 hours of severe sepsis presentation. A total of 25 patients should have received 30 milliliters per kilogram of intravenous (IV) crystalloid. Of those 25 patients, only 7 (28 percent) received adequate fluid resuscitation within 3 hours of presentation. A second lactate level should have been drawn within 6 hours of severe sepsis presentation in 31 patients. Of those, only 12 (39 percent) had a second level drawn. Of the 55 patients included, 12 patients met criteria for vasopressor initiation and 15 patients met criteria for volume status reassessment. Vasopressors were initiated promptly in 4 (33 percent) of the 12 patients and volume status was reassessed in 8 (53 percent) of the 15 patients.

Conclusion: Opportunity for improvement in the management of sepsis was identified at our facility. Sepsis bundle compliance was low for IV fluid resuscitation, re-evaluation of serum lactate level, prompt initiation of vasopressors, and volume status reassessment. The data collected will be used as a comparison for evaluation of bundle compliance after implementation of sepsis protocols at our facility. The results will be used to enhance ongoing staff education.

Poster Title: Assessing medication adherence and the use of technology in hypertensive patients.

Primary Author: Michael Cooney, University of Rhode Island College of Pharmacy, Rhode Island; **Email:** michael_cooney@my.uri.edu

Additional Author (s):
Lisa Cohen
Monica Raziq

Purpose: Drug therapy for chronic illness is effective in combating illness if they are taken as prescribed. Patients have poor adherence due to many reasons, such as the cost of the medicine and healthcare visit, low health literacy, and side effects. The purpose of this study is to assess medication adherence and if healthcare-focused mobile apps affect patient adherence, specifically in patients with hypertension. This will provide pharmacists and other healthcare professionals a better understanding of why patients have low medication adherence and if an app can help improve it.

Methods: Participants were recruited to take our survey through Facebook posts. Our Facebook post encouraged participants to take the survey if they had hypertension and were taking medication(s) to control their blood pressure. A Google Forms survey was used to collect responses. The Google Forms survey was set to only obtain one result per participant, and all of the surveys were completed anonymously. In addition to the Google Forms survey, paper surveys were also distributed for participants who were unable to use computers or without access to the internet. Participants were included in the study if they had high blood pressure and were taking prescriptions to control their blood pressure. Since many subjects with hypertension may also be taking medications for other chronic and acute conditions, the data obtained from these patients were also included in our results. Patients were excluded if they did not have a prescription for hypertension. The survey assessed medication adherence using the Morisky scale (MMAS-4), reasons for poor adherence, and the use of technology through apps to assist in improving adherence. The Morisky scale assessed patient adherence levels and classified then as having high, medium, or low adherence.

Results: Twelve participants completed the survey and the overall Morisky score was 2.3 with a standard deviation of 1.2. The most commonly reported adherence issues were: forgetfulness (66.7%), busy lifestyle (41.7%), not picking up prescriptions on time (33.4%), high drug cost (33.4%), and no insurance (33.3%). Forty one percent of those surveyed have ever used a phone app to improve overall health, and 83.3% would use an app that reminded the user when to take medications. Seventy-five percent of the participants answered that an app would be "helpful" or "very helpful" in improving the number of missed doses. Only 25% of those surveyed would pay 99 cents to obtain a medication adherence app, all other survey participants would expect the app to be free to the consumer. Linear regression modeling found no statistically significant difference with the use of technology on adherence or Morisky score (coefficient of determination is 0.183).

Conclusion: This survey shows that some of most common reasons for missing a dose of medication are forgetfulness, busy lifestyle, not picking up prescriptions on time, and cost issues. The use of a phone app to increase adherence was not found to improve the Morisky score, which suggests that use of a phone health app is not strongly correlated with increased adherence. Future studies should assess the effectiveness of an app that can provide useful adherence data to a health professional and help identify or address the factors responsible for decreased medication adherence.

Poster Title: Student pharmacist integration into an outpatient infectious disease clinic

Primary Author: Shannon White, Texas A&M College of Pharmacy, Texas; **Email:** swhite1@tamhsc.edu

Additional Author (s):
Andrea Luce

Purpose: Infections are among the most common causes for hospital admissions and are associated with a high economic burden. However, novel patient care strategies have allowed for early discharge of infectious disease (ID) patients, which has demonstrated improved patient satisfaction and decreased patient cost. Outpatient parenteral antibiotic therapy (OPAT) is a subtype of outpatient therapy that is now widely used throughout the United States. However, outpatient treatment of ID patients and particularly OPAT call for increased patient education and clinical decision support for clinicians. Fourth-year student pharmacists are well-prepared to step up to these challenges.

Methods: Two student pharmacists were enrolled in an infectious disease (ID) advanced pharmacy practice experience (APPE) rotation at a Texas county hospital lasting six weeks. Throughout the course of the rotation, students were given various projects to complete to meet the needs of the hospital's ID team, each geared towards improvement of the outpatient ID clinic.

Results: Three separate and unique projects were started and completed. An outpatient IV antibiotic stability guide comparing stability lengths of all formulary IV antimicrobials was developed to ease physician workflow and improve patient convenience. A patient letter discussing tips, adverse effects, and management strategies for patients on long-term outpatient trimethoprim-sulfamethoxazole was developed to improve patient understanding. A combination patient letter and pocket guide for a subset of patients with recurrent or complicated UTIs was developed to improve patient understanding and cost. Each of these products are also in the process of being translated to Spanish in order to reach a larger patient population.

Conclusion: By the end of the six-week rotation, the four finished products were already being utilized by clinicians in the outpatient ID clinic for clinical decision support or being handed out to patients for education, depending on the purpose of the specific product. This type of example should be followed by other ID APPE elective rotations to increase student learning and inter- professional collaboration. Overall, response to the projects was positive, and student pharmacist assistance with and integration into the outpatient ID clinic was well-received.

Submission Category: Ambulatory Care

Poster Title: Evaluation of the timing of physician intervention in ambulatory diabetic and hypertensive patients

Primary Author: Whitney Strong, Texas A&M Health Science Center Irma Lerma Rangel College of Pharmacy, Texas; **Email:** whitneystrong89@gmail.com

Additional Author (s):
Quynh Nguyen
Amanda Beck
Anthony Colavecchia

Purpose: Diabetes mellitus and hypertension are two of the leading causes of morbidity and mortality in the United States. Currently, the standard of care for diabetes and hypertension management are defined by the Eighth Joint National Committee and American Diabetes Association. Initiating timely and appropriate pharmacotherapy in uncontrolled diabetic and hypertensive patients is imperative to mitigate long-term comorbidities from developing and reducing healthcare costs. The purpose of this study is to evaluate when ambulatory physicians initiate interventions in diagnosed diabetes and hypertension patients in an outpatient clinic in order to identify where ambulatory pharmacy services may improve patient care.

Methods: The institutional review board waived this single center, retrospective, cohort study. All patients who were scheduled for an outpatient visit from July 1, 2016 to September 10, 2016 who had a documented diagnosis of diabetes, hypertension, or both, were included in the study. Data elements included age, gender, hemoglobin A1c, blood pressure, utilization of first line therapy for hypertension or diabetes, utilization of statin therapy, and types of interventions that physicians made. The primary endpoint was to determine the percent of patients with uncontrolled blood pressure or hemoglobin A1c value who did not receive an intervention by a physician. Secondary endpoints included the average blood pressure and hemoglobin A1c when an intervention was made, and percent of patients on appropriate first line therapy for hypertension or diabetes. The primary and secondary endpoints were analyzed using descriptive statistics.

Results: Of 121 patients seen by the ambulatory physicians from July 1, 2016 to September 10, 2016, 112 eligible patients were included in the study. Of the 103 diabetic patients, 34 percent had uncontrolled diabetes, and 63 percent of these patients did not receive an intervention during office visit. Of the 96 hypertensive patients, 39 percent were uncontrolled, and 81 percent of these patients did not receive an intervention during office visit. The average hemoglobin A1c value where physicians made an intervention was 9 percent and the average systolic and diastolic blood pressures value were 165 and 79 mmHg, respectively. Appropriate first line therapy was prescribed to 39 percent of diabetic patients, and 65 percent of hypertensive patients.

Conclusion: Majority of uncontrolled diabetic and hypertensive patients did not receive pharmacological intervention during ambulatory care visits. These results revealed a gap in appropriate patient care and also provide a foundation for the implementation of pharmacy services in the ambulatory care setting.

Poster Title: Evaluation of sequential compression device compliance in adult general medical patients at three consecutive time points: a point-prevalence study

Primary Author: Monica Pham, Texas A&M Irma Lerma Rangel College of Pharmacy, Texas;
Email: monica_pham17@yahoo.com

Additional Author (s):
Tracey Thomas
Ekim Ekinci
Anthony Colavecchia
Melanie Ruegger

Purpose: Venous thromboembolism (VTE), comprised of deep vein thrombosis and pulmonary embolism, is the most common preventable cause of in-hospital mortality. Use of a sequential compression device (SCD) may be one intervention to prevent VTE occurrence in a hospital setting. While a limited number of studies have evaluated SCD compliance in critical care and surgical patients, recent studies have yet to evaluate SCD compliance in general medical patients over consecutive time points. Therefore, the purpose of this study is to assess SCD compliance in adult general medical patients.

Methods: The institutional review board waived this observational, single-center point-prevalence study which evaluated the proportion of SCD compliance over consecutive time points. Patients were included in the study if there was an active SCD order in the current admission electronic medical record, and they were available for assessment during at least one time point. Patients were excluded from any of the time points if they were discharged, moved to a different unit, or unavailable during time of data collection. Data collection occurred between 0600-0800, 1400-1600, and 2000-2200 hours. The primary endpoint was to determine and compare the proportion of adult general medical patients compliant with an active SCD order at 3 individual time points during a 24-hour period. A patient was considered compliant during a time point if the patient was in bed or sitting in a chair with SCDs appropriately worn and turned on, or if the patient was ambulating. The following data were collected for each patient: demographic information, pharmacological prophylaxis, and Caprini Risk assessment.

Minitab was utilized to calculate SCD compliance percentage for each time point and p-values comparing percent compliance among the consecutive time points.

Results: Of the 189 available patient beds, SCD compliance was assessed for 68 patients who had an active SCD order. The number of patients meeting inclusion criteria from first, second and third time points were 66, 51, and 46, respectively. Percent compliance at each time point was 12.1 percent, 15.7 percent, and 15.2 percent, respectively. Two-tailed p-values comparing the first and second time point, second and third time point, and first and third time point were 0.6, 1.0, and 0.78, respectively.

Conclusion: A large proportion of patients were noncompliant with their active SCD order, raising concern for the development of an in-hospital VTE. Data from this study demonstrate no significant difference in SCD compliance in general medical patients among consecutive time points within a 24-hour period. Results may have been impacted by the small sample size and should be repeated with a larger sample in order to detect a difference in compliance among the time points and reduce type II error probability. Our results support conducting a larger point prevalence study.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Evaluative Study

Session-Board Number: 2-346

Poster Title: Evaluation of hydromorphone (Dilaudid®) PCA usage at a large quaternary hospital

Primary Author: Brenda Opande, Texas Southern University, Texas; **Email:** bonyaboke@yahoo.com

Additional Author (s):
Marizu Ndubuizu
Bryan Hildebrandt
Joshua Blackwell

Purpose: Opiates, including hydromorphone, represent one of the four drug categories causing more than 60% of serious adverse events in the United States. Leading factors attributed to the misuse of hydromorphone include misunderstanding of the equi-analgesic dosing of hydromorphone compared to morphine and improper labeling practices. It is important to develop effective management strategies to optimize patient safety when utilizing hydromorphone. The purposes of this medication use evaluation are to assess prescribing practices for hydromorphone PCAs, to assess the appropriate use of hydromorphone, and to determine if the use of hydromorphone is correlated to adverse events.

Methods: This is a retrospective chart review of randomly selected patients who were admitted to CHI St. Luke's Health – Baylor St. Luke's Medical Center (BSLMC) from October 1, 2015 through December 31, 2015. A list of all patients receiving hydromorphone who fit the inclusion and exclusion criteria was obtained from the electronic health record database. At BSLMC, the PCA order set provides a defined strategy for PCA dosing, which includes the following options: low dose for opiate naïve patients, medium dose for moderate opiate usage, high dose for opiate tolerant patients and "other" dosing as specified by the physician. For each eligible patient, information was obtained from the patient's medical record including demographic (age, gender, etc.), indication for therapy, dose based on the order set, and adverse effects related to hydromorphone PCA use.

Results: This study randomly reviewed 150 patient profiles. Hydromorphone PCA was used for post-operative pain (44/150, 29%) and cancer pain (23/150, 15%); however, 82/150 or 55% of PCA use was for other types of pain. Amongst 53/150 (35%) patients with a past history of

opioid use, the average morphine equivalent dose per day (MEDD) was 33 mg. Patient education, which documents the assessment of patient competency and understanding of PCA teaching, was completed for 123/150 (82%) patients. Twenty patients (13%) received a bolus dose prior to PCA administration with an average dose of 0.5 mg and average pain score of six. Fifty-three (35%) patients with an average pain score of 5.7 received higher doses of PCA than the low-dose opioid naïve order set despite being opioid naïve. Sixty (40%) patients received a change in their PCA dose and 80% (120/150) of the prescribers used the "other" dosing PCA option instead of using moderate-dose PCA. The main reason for discontinuation of the PCA was conversion to alternate therapy (99/150, 66%). During this study period, no patient discontinued the PCA due to adverse drug events, nor was naloxone administered and none of the patients had required a call to the Rapid Response Team.

Conclusion: The results of this study demonstrated some opportunity for improvements with the use of hydromorphone PCA at our institution. Since we have many new staff members at our institution, a plan to help educate these newly hired employees on our PCAs or update our PCA policy would be beneficial to help improve patient safety. Pharmacists should be proactive in making sure all PCAs prescribed adhere to our institution's policy and proper documentation is within the patient's chart

Poster Title: Incidence of postoperative acute kidney injury after exposure to prothrombin complex concentrate in patients undergoing orthotopic liver transplantation

Primary Author: Jesse Harris, Texas Southern University, Texas; **Email:** jeharris4@houstonmethodist.org

Additional Author (s):
Jeena Thomas
David Cohen
Eric Salazar
Anthony Colavecchia

Purpose: Patients who are undergoing orthotopic liver transplantation (OLT) may experience major blood loss during surgery. Strategies to prevent or mitigate blood loss in these procedures includes administration of prothrombin complex concentrate (PCC). Acute kidney injury (AKI) is associated with use of PCC in cardiac surgery. Proposed mechanisms include thromboembolic events and/or hypovolemia secondary to acute blood loss. We hypothesized that use of PCC is associated with AKI in OLT. The purpose of this study is to describe the incidence of AKI in patients undergoing OLT who are exposed to PCC versus patients who do not receive PCC during transplantation.

Methods: This is a single centered, retrospective, observational study of patients undergoing OLT from December 2013 to April 2016 at Houston Methodist Hospital. This study was expedited by the institutional review board. Patients were included in the study if they were greater than 18 years of age and undergoing OLT. Patients were excluded from the analysis if they were undergoing simultaneous heart or lung transplantation, or no documented anesthesia operative note was in the electronic medical record. The primary endpoint was a measure of the incidence of AKI as defined by the KDIGO criteria. For the primary analysis, a chi-square test was utilized to compare the incidence of AKI among the two cohorts. The secondary endpoint of this study was to observe the difference between patients who required intermittent hemodialysis (IHD) or continuous renal replacement therapy (CRRT) preoperatively versus postoperatively.

Results: Amongst the 211 patients observed, 204 met the inclusion criteria. The two cohorts consisted of 39 patients (19 percent) who received PCC intraoperatively and 165 patients (81 percent) who did not. Between the two groups, no significant difference was observed in the incidence of AKI as defined by the KDIGO criteria. The primary outcome of AKI was observed in 13 out of 39 patients (33.3 percent) in the PCC group as well as 55 out of 165 patients (33.3 percent) in those who did not receive PCC. Excluding patients who were on hemodialysis prior to OLT, no significant difference was observed in patients who required hemodialysis postoperatively in the PCC group compared to the control (P-value 0.3). Patients who received PCC intraoperatively were observed to have a reduced dialysis requirement pre to postoperatively (OR, 0.143 [95 percent CI, 0.003 to 1.112]). The control group was observed to have an increased hemodialysis requirement pre to postoperatively (OR, 2.714 [95 percent CI, 1.093 to 7.641]).

Conclusion: Patients undergoing OLT who were exposed to PCC were found to have no significant difference in the incidence of AKI compared to those who were not exposed. Additionally, in patients who received intraoperative PCC that required hemodialysis prior to transplantation, there was an observed reduction in the postoperative requirement of hemodialysis. Further, larger scale studies are recommended to reduce the risk of type II error.

Poster Title: Observe the role of pegfilgrastim via on-body injector on neutrophil production

Primary Author: Demi Chan, Texas Southern University, Texas; **Email:** d.chan3382@student.tsu.edu

Additional Author (s):
Jesse Harris
Nirmal Koruthu
Rodney Hunter

Purpose: Patients undergoing chemotherapy have diminished capacity to fight off infection due to neutropenia experienced as a result of the agents utilized in their treatment regimen. OnPro™ is a wearable on-body injector that infuses peg-filgrastim, a pegylated form of recombinant human granulocyte colony stimulating factor (GCSF). Patients who are treated with GCSF have an increased neutrophil count as a result of stimulating the bone marrow to increase the production of neutrophils that enhance patient's immune function. This study is designed to observe the increase in neutrophil production post exposure to GCSF via the on-body injector.

Methods: This is a single centered, retrospective, observational study of patients undergoing chemotherapy that required the use of GCSF from January 2016 to August 2016 at Memorial Hermann Cancer Center in Houston, Texas. Patients were included in the study if they were greater than 18 years of age, undergoing chemotherapy, and were exposed to GCSF via an on-body injector. Patients were excluded from the analysis if they had missing pre-exposure lab data, missing follow-up visits within 30 days, or had missing laboratory data post-exposure. The primary endpoint of this study was to measure the mean change in absolute neutrophil count (ANC) from baseline. The secondary endpoint of this study was to observe the mean increase in white blood cell count (WBC) from pre-exposure to post-exposure of GCSF.

Results: A total of 72 on-body injection doses were included in the study, of which, 21 met the inclusion criteria. The mean age was 63 years; 52 percent (n= 11) were male and 48 percent (n= 10) were female. The primary outcome of mean change in ANC was observed to decrease as compared to baseline by 16 percent in patients who were exposed to GCSF utilizing an on-body

injector. The secondary outcome of mean change in WBC was observed to be a decrease by seven percent compared to baseline in patients who received GCSF.

Conclusion: Patients undergoing chemotherapy who were exposed to GCSF via on-body injector were observed to have a mean decrease in ANC by 16 percent within 30 days of exposure. Additionally, there was a mean decrease in WBC by seven percent post-exposure to GCSF. Larger studies are needed to increase the external validity of this study and reduce the risk of a type II error.

Poster Title: Retrospective assessment of appropriate usage of oritavancin in the treatment of cellulitis at a healthcare system

Primary Author: Abdul Gabisi, Texas Southern University College of Pharmacy and Health Sciences, Texas; **Email:** manaf23@hotmail.com

Additional Author (s):
Enock Anassi
Flora Estes

Purpose: Oritavancin diphosphate (Orbactiv) is a lipoglycopeptide with concentration-dependent bactericidal activity. The pharmacodynamics/pharmacokinetic profile of oritavancin indicate an extended half-life elimination of over ten days (245 hours). This unique characteristic of oritavancin allow for one dose infusion to treat susceptible organisms. The focus of this medication use evaluation is to assess appropriate usage of oritavancin and the clinical, social, and pharmacoeconomic impact of one dose treatment of patients in two emergency centers of a healthcare system. The two emergency centers are of a level one and level three trauma center.

Methods: The institutional pharmacy and therapeutics committee approved the evaluation of oritavancin usage. A daily generated information technology report captured patients that were administered oritavancin within a period of 5 months (April-August 2016). A total of 20 patients were identified thus far and evaluated with regards to clinical efficacy and social factors impacting patient nonadherence. The following data were collected for each patient; demographics, indications, ordering physicians, dosage of oritavancin, antibiotics used prior to oritavancin for the same indications, failure of home oral antibiotics, cultures and sensitivity, clinical safety, radiology studies, temperature, white blood count, socioeconomic issues, and psychiatry disease or cognitive impairment that will impede medication management. In addition to data collected above, oritavancin use was also evaluated with regards to observation period of patients prior to physician ordering oritavancin, any compliance issues, reoccurrence of recently diagnosed infection that was previous treated with oral or intravenous antibiotics, documentation for the use of oritavancin in patient chart, additional antibiotics used with or after oritavancin dose, duration of treatment, patient monitoring, and adverse

events. These patients were also assessed whether they were candidates for admission based on factors like nonadherence or severity of the infection. Considering the cost of the drug, compliance, and admission, the pharmacoeconomic assessment was performed.

Results: Of the 20 patients, 16 were males and 4 were females. Overall, ninety percent of the patients (18) treated with oritavancin showed clinical improvement. Out of the twenty patients, eight were homeless, two are disabled, and four had psychiatric related conditions. Out of twenty patient cases, forty-five percent (9) had previous treatment with oral or intravenous antibiotic. The oral antibiotics prescribed that failed were clindamycin and cephalexin. Twenty five percent (5) of the patients were deemed to be noncompliant following failure of home oral antibiotics and consequentially were treated with oritavancin. Twenty percent (4) were compliant with their oral medications but yet were not cured with these prescribed oral antibiotics. Fifteen percent (3) experienced an adverse event following oritavancin treatment, which included itching, rash, and hand burning. All these patients who were candidates for admission benefited from one dose oritavancin.

Conclusion: Oritavancin usage of one dose regimen allowed for the successful treatment of patients who could otherwise be admitted. This led to cost of admission avoidance and cost of medication incompliance. The institution also utilized patient assistance program that minimized any incurred cost. More data will be collected to confirm our initial findings.

Poster Title: Automated robot compounding technology: How does it fit into your oncology pharmacy?

Primary Author: Justin Fernandes, Texas Southern University College of Pharmacy and Health Sciences, Texas; **Email:** justinferna@gmail.com

Additional Author (s):
Sunny Bhakta
Anthony Colavecchia

Purpose: Automated robotic compounding technology (ARCT) provides a promising future for the compounding of hazardous medications by improving preparation safety and accuracy. Limited literature exists regarding reported versus actual preparation times and may hinder the adoption of ARCT by hospitals and health-systems. In addition, data is lacking on the acceptance of ARCT by pharmacy personnel after implementation into daily workflow. The technology acceptance model (TAM) is considered an accurate measurement tool to assess information systems adoption. The purpose of this study is to assess actual versus reported ARCT preparation time and acceptance of ARCT based on the TAM.

Methods: The Houston Methodist Hospital (HMH) oncology satellite dispenses over 30,000 IV hazardous preparations per year. ARCT was implemented to provide safety and operational efficiency to our satellite pharmacy. This study consisted of two analyses: an observational time study comparing actual versus reported preparation time of all compounds made by the ARCT (i.v.STATION ONCO, Health Robotics) during a 3 week period in September 2016, and a questionnaire provided to all staff interacting with i.v.STATION ONCO. The time study included four antineoplastic products: cyclophosphamide, carboplatin, cisplatin, and oxaliplatin. Actual preparation times consisting of preparation start and end time were extracted from the robotic database. Actual preparation times were compared to manufacturer reported preparation times. The results were stratified by each medication compounded by the ARCT. The primary endpoint of the time study was to determine the difference in actual versus reported preparation time.
Two weeks post implementation of i.v.STATION ONCO, a 25-item TAM questionnaire was administered to pharmacy staff. The TAM questionnaire assesses individuals' perceived

usefulness (PU), perceived ease of use (PEOU), and attitude towards the adoption of technology. Questionnaire items were scaled from 1 (strongly disagree) through 5 (strongly agree) on a Likert Scale. The primary endpoint of the questionnaire was to determine the pharmacy staff's PU, PEOU, and attitudes towards using i.v.STATION ONCO. The Institutional Review Board waived this observational study.

Results: During a 3 week period in September 2016, 56 preparations were made in i.v.STATION ONCO: 34 carboplatin, 16 cyclophosphamide, 4 cisplatin, 2 oxaliplatin. The mean preparation time for all products was 7.6 minutes (plus or minus 3.1 minutes), and the mean preparation times for carboplatin, cyclophosphamide, cisplatin, and oxaliplatin were 7.5 minutes, 6.4 minutes, 11.5 minutes, and 11.1 minutes, respectively. The mean difference in preparation time of i.v.STATION ONCO was 2.4 minutes greater than the reported preparation time (p-value less than 0.01).

Of the 16 pharmacy personnel who completed the questionnaire, 10 pharmacists and 6 pharmacy technicians participated. The mean years of practice among the pharmacy personnel who completed the questionnaire was 12 years. All of the respondents believed i.v.STATION ONCO would decrease or not change the number of medications errors. The pharmacy staff perceived the ARCT as neither easy nor difficult to use (median equals 3). Questionnaire responses showed that participants attitude towards the use i.v.STATION ONCO is positive (median equals 3.5). Staff responses revealed the PEOU was high (median equals 4).

Conclusion: The actual preparation time of hazardous products by i.v.STATION ONCO was significantly greater than the reported preparation times. Using the TAM, employees at HMH found the ARCT useful in preventing medication errors, not difficult to operate, and a positive attitude towards the robot 2 weeks after implementation. Other institutions must consider actual versus reported time studies to appropriately evaluate efficiency of the robot as well as assess employee's willingness to adopt ARCT to ensure successful implementation of the technology.

Poster Title: Comparing the efficacy of palbociclib with letrozole versus palbociclib with fulvestrant in an accredited institutional cancer setting

Primary Author: Steven Nguyen, Texas Southern University College of Pharmacy and Health Sciences, Texas; **Email:** steven.nguyen5677@gmail.com

Additional Author (s):
Anju Johnson
Joaquina Guerrero
Rodney Hunter

Purpose: Palbociclib is a cyclin dependent kinase 4/6 inhibitor that is effective in patients who are Hormone Receptor-positive and Human Epidermal Growth Factor Receptor 2-negative, who have built first line resistance to endocrine therapy. Palbociclib inhibits the progression of cancer cells from G1 to S phase, which thereby prevents the proliferation of breast cancer cells. This process is regulated by cyclin dependent kinases 4 and 6. The purpose of this study is to observe the efficacy of two treatment groups at a regulated cancer center: palbociclib plus fulvestrant with or without goserelin to palbociclib plus letrozole with or without goserelin.

Methods: The data was collected from Memorial Hermann Oncology Clinic within the Texas Medical Center, under the supervision of Dr. Rodney J. Hunter, who is the clinical oncology pharmacist as well as a spokesperson for Pfizer. In this prospective, open label, observational, intention-to-treat study, pre/peri/postmenopausal women (n=15) with advanced metastatic Hormone Receptor-positive, Human Epidermal Growth Factor Receptor 2-negative breast cancer were enrolled, who had previously not received systemic chemotherapy. Patients either received palbociclib (125 mg intravenously 3 weeks on/ 1 week off) with letrozole (2.5 mg by mouth, once daily), or palbociclib (125 mg intravenously 3 weeks on/ 1 week off) with fulvestrant (500 mg intramuscularly on days 1, 15, and 29 for the first month, then 500 mg once monthly), with or without goserelin depending on patient's menopausal status. Treatment was continued further until disease progression, intolerance to therapy, or death. The primary endpoint is progression-free survival and overall survival to determine the efficacy of palbociclib that was shown in previous data. The secondary endpoint is the objective response,

which is the tumor size shrinkage, in relation to palbociclib treatment. Patient accrual is ongoing with an anticipated completion date of February 2017.

Results: A total of 15 patients were treated (palbociclib with letrozole with or without goserelin (n=8); palbociclib with fulvestrant with or without goserelin (n=7)), and the progression-free survival for patients that had progressed through treatment was 11.9 months versus 7.14 months, respectively. Objective response (tumor size shrinkage) was reported showing a decrease in the diameter of tumor in patients who were taking palbociclib with letrozole. One patient was deceased before receiving the full treatment cycle; however their data has been included in the study. Another patient who received palbociclib with fulvestrant was Human Epidermal Growth Factor Receptor 2-positive, which may cause skewing of the data. The study is ongoing and data may vary in the future.

Conclusion: In summary, palbociclib with letrozole showed an increased progression-free survival as first line treatment agent when used in pre/peri/post-menopausal women. However, there was a decreased progression-free survival seen in palbociclib with fulvestrant when used as second or third line therapy for metastatic breast cancer. Median progression-free survival and median overall survival has yet to be reached in the study. Studies with larger sample sizes should be conducted in the future for better results.

Poster Title: Incidence of early hepatic artery thrombosis in orthotopic liver transplant patients receiving intraoperative epsilon-aminocaproic acid (EACA) and/or four-factor prothrombin complex concentrate

Primary Author: Emmanuel Njigha, Texas Southern University College of Pharmacy and Health Sciences, Texas; **Email:** enjigha@yahoo.com

Additional Author (s):
Eric Salazar
Anthony Colavecchia

Purpose: The most deleterious vascular complication to occur post orthotopic liver transplantation (OLT) is hepatic artery thrombosis (HAT), which occurs in 2 to 9 percent of OLT recipients. The mortality and re-transplantation rate in liver transplant patients that undergo HAT is approximately 50 percent. Many factors influence the development of HAT including operative and non-operative elements. The use of four-factor prothrombin complex concentrate (PCC4) and epsilon-aminocaproic acid (EACA) intraoperatively may promote an intrinsic hypercoagulative state that may lead to the development of thrombotic complications. The purpose of this study is to assess the safety of administering PCC4 and/or EACA during OLT.

Methods: This study is a single-center, retrospective, cohort study conducted at a large academic medical center. Patients greater than or equal to 18 years of age who underwent OLT from December 2013 to April 2016 and had a documented anesthesia operative note in the electronic medical record were included in the study. Patients who received a heart or lung transplant during the OLT were excluded from this study. The primary safety endpoint was the proportion of patients receiving OLT who developed early postoperative HAT after receiving EACA, PCC4, or both compared to patients who did not receive these medications. Patients were assessed for HAT from postoperative day zero to postoperative day 3. Postoperative day 3 was defined as 72 hours immediately after the end of surgery documented in the anesthesia notes. Abdominal Doppler ultrasounds were reviewed to measure the occurrence of any signs of thrombosis in these patients as well as documented reasons for patients returning to the operating room. SAS v9.3 statistical software was used for all statistical analysis, and chi-square test was used to assess the primary endpoint.

Results: Amongst the 211 patients observed, 204 met the inclusion criteria. Thirty-nine patients (19 percent) received PCC4 intraoperatively, 101 (50 percent) patients received EACA, and 25 (12 percent) received both medications. Fifty patients (25 percent) had documented abdominal Doppler ultrasounds, and 4 patients returned to the OR due to suspicion of HAT. Three of the 4 patients that returned to the operating room were confirmed to have HAT after exploration of the hepatic artery (1.5 percent incidence of HAT). The development of early HAT was documented in the operative/procedure report, however abdominal Doppler ultrasounds did not validate these findings. None of these patients received PCC4, 2 patients received EACA intraoperatively, and 1 patient did not receive either medication intraoperatively.

Conclusion: Patients undergoing OLT who were exposed to PCC4 as well as the combination of PCC4 and EACA were found to have no difference in the incidence of HAT as compared to those who did not receive either therapy. Those patients who received EACA alone seemed to be at an increased risk of developing HAT, however this was not proven statistically. No conclusions can be made from the study due to the small sample size and short term observation. Additional studies should be conducted to evaluate the incidence of thrombosis in this patient population beyond postoperative day 3.

Poster Title: Ethnic difference in glucose control and weight loss after gastric bypass surgery in a diabetic population

Primary Author: Betsy Benny, Texas Southern University College of Pharmacy and Health Sciences, Texas; **Email:** b.benny0764@student.tsu.edu

Additional Author (s):
Hong Tieu
Jeena Thomas
Vadim Sherman
Lily Cheung

Purpose: Type 2 diabetes is one of the major comorbidities associated with obesity. Roux en Y gastric bypass (RYGB) procedures have emerged as an important treatment modality for the obese patients with diabetes. However, demographic factors such as ethnicity may affect the procedure outcomes and the information regarding the impact of ethnicity on glucose control after gastric bypass is limited. The purpose of this study is to investigate whether differences in glucose control and excess weight loss exist among ethnic groups in a type 2 diabetic population undergoing RYGB.

Methods: This retrospective observational study was approved by the Institution of Review Board. Eighty-three of ninety-one adult patients with type 2 diabetes who underwent RYGB from 2012 to 2014 at Houston Methodist Hospital in Texas were included in the study. Two patients were excluded due to lack of follow up data and six were excluded because of unknown ethnicity. The data for this study were obtained from electronic databases and medical records at pre operation and at 3, 6, and 12 months after surgery. Information on patients' height, age, gender, and ethnicity were obtained prior to surgery; whereas weight and pertinent lab values were obtained both prior to surgery and at each follow-up visit. The difference in hemoglobin A1c (HbA1c) value and percent excess weight loss were calculated for each patient at each follow up visit from the preop value. Patients were grouped according to their ethnicity, i.e. Caucasian, African Americans, and Hispanic. The primary endpoint measurements were the difference in mean change of HbA1c and mean percent excess weight

loss among the ethnic groups, using analysis of variance (ANOVA) and Tukey HSD post hoc analysis. A p-value of less than 0.05 was considered statistically significant.

Results: From 83 patients included in the study, 52 were Caucasians (77 percent females), 21 were African Americans (81 percent females), and 10 were Hispanics (50 percent females). The mean age was 53 plus or minus 11 years. The differences in mean HbA1c among the three ethnic groups were not statistically significant at 3, 6, or 12 months after RYGB. However, African Americans showed the highest decrease in mean HbA1c at 12 months after surgery (1.59 with SD 0.84), as compared to Caucasians (1.27 with SD 1.09), and Hispanics (0.3 with SD 0.35). The percent excess weight loss among the three ethnic groups was only significantly different at 12 months after surgery where Caucasians showed the highest weight loss with mean percent excess weight loss at 62.6 with SD 16.4, as compared to African Americans (52.5 with SD 20.4) and Hispanics (46.1 with SD 23.2), although Tukey HSD post hoc analysis did not show significant differences between the groups.

Conclusion: Our finding from this study was consistent with the published information that no significant difference was found among ethnic groups regards to HbA1c reduction up to 12 months after RYGB procedure. In addition, a significant difference in percent excess weight loss at 12 months after surgery was found among the ethnic groups, and Caucasians had a higher excess weight loss at this time point as compared to the African American and Hispanic counterparts. These findings would need to be confirmed in a larger size and prospective study.

Poster Title: Retained symptomatic control following discontinuation of proton pump inhibitors after extended use: a pharmacist-led medication use evaluation

Primary Author: Kathryn Velasquez, Texas Southern University College of Pharmacy and Health Sciences, Texas; **Email:** kklorraine1011@gmail.com

Additional Author (s):
An Alvarez
Dr. Portia Davis

Purpose: Gastroesophageal Reflux Disease (GERD) is usually not a life-threatening disease; however, symptoms affect patients' quality of life. Proton-pump inhibitors (PPIs) are first-line agents in treating GERD, which affects 40 percent of American adults monthly. Esomeprazole (Nexium) ranked third in total sales, with 13.2 million prescriptions costing $4.7 billion in the US for the year 2015. Overutilization of PPIs occurs primarily in patients requiring long-term treatment. The objective of this project is to determine whether patients of a local charity clinic maintain symptom control after discontinuing PPIs when clinically indicated, under evaluation of a pharmacist-led medication utilization program.

Methods: The study was conducted as a prospective, medication use evaluation (MUE). This study was exempted by the International Review Board at Texas Southern University and was approved by the clinic administration. Data was collected and recorded without patient identifiers to ensure patient confidentiality. Reports were generated through the electronic medical record system, Sevocity, identifying all clinic patients receiving PPI therapy from January 2013-June 2015. After one year, patients were contacted for a trial discontinuation of PPI therapy after a pharmacist-led educational session. Pharmacist interns followed-up with these patients by phone on a monthly basis to assess their quality of life through a survey assessing severity and frequency of symptoms. Patients unable to maintain symptom control after six months of the intervention were referred back to their primary care physician for further evaluation.

Results: One hundred patients were contacted via telephone from May through September 2016 to assess their GERD symptoms after discontinuation of PPI therapy; each patient was contacted two times. The initial call was a 15 minute counseling session, asking patients to consider implementing a healthy lifestyle, and using an over the counter (OTC) H2-antagonist if symptoms occurred. After three months, patients received a second call and administered a survey that assessed their symptoms to date. In conclusion 25% (n=25) of patients were no longer using a PPI, but adjusted their diet if symptoms occurred. After a three week trial, 75% (n=75) of patients continued to have symptoms and were unable to be completely off of a PPI; 22.6% (n=17) of these patients used OTC H2-antagonist daily to control their symptoms, and 12% (n=9) used PPIs as needed for symptom control. A total of 57.3% (n=43) of patients continued taking PPIs because they were not ready for lifestyle changes or OTC H2-antagonist did not relieve their symptoms. Patients that agreed to discontinue PPI use were generally 49 years or younger and took fewer maintenance medications. Six percent (n=6) of patients were dropped from the study after 3 failed attempts to contact them.

Conclusion: Discontinuation from PPI therapy or step-down therapy with an OTC H2-antagonist was possible for patients with mild-moderate GERD symptoms when mediated by pharmacist counseling and telephone follow-up. Longer follow-up times will be evaluated in the future in order to assess long-term success of the intervention.

Poster Title: Treatment Experience with Metastatic Breast Cancer with the use of Novel Agent CDX-011

Primary Author: Sally Enemchukwu, Texas Southern University College of Pharmacy and Health Sciences, Texas; **Email:** s.enemchukwu@gmail.com

Additional Author (s):
Trelon Land
Erica Lindsey
Brandy Wilkerson
Rodney Hunter

Purpose: The purpose of this study is to evaluate the use of novel agent CDX-011 in treating patients who have metastatic, triple negative breast cancer. Metastatic breast cancer, also referred to as advanced or stage IV breast cancer, has the opportunity to spread to other parts of the body. Triple negative breast cancer, which accounts for approximately 10-20% of breast cancers, refers to cancer that is negative for estrogen receptors (ER-), progesterone receptors (PR-), and human epidermal growth factor receptor 2 (HER2-), thus "triple negative". This type of cancer is sometimes associated with a poor prognosis, and therapy is limited.

Methods: This study is a randomized controlled trial conducted in a comprehensive Cancer Center, approved through the hospital's institutional review board. The primary outcome is to evaluate the use, efficacy, and toxicities of the novel agent CDX-011 in metastatic, triple negative breast cancer expressing glycoprotein NMB (gpNMB). CDX-011 is considered targeted therapy that targets and binds to cancer cells overexpressing the gpNMB. This binding allows the drug to interfere with cell growth of the cancer cell and leads to cell death. Eligible patients enrolled in the study will be randomly assigned to receive CDX-011 treatment, and will be monitored for safety, efficacy and toxicity. The primary end points include disease-free progression and overall survival. Secondary end points consist of adverse side effects, response rates, and treatment failure.

Results: Patient accrual has been stagnant secondary to the infrequent expression of the gpNMB protein in breast cancer tissue. Two patients at the Cancer Center have been enrolled on the trial thus far. The median progression free survival and overall survival have not yet been reached in the respective trial. Interim data from Cancer Center yields a PFS of 4.5 months and OS could not be determined at the time of analysis.

Conclusion: Patient accrual is still underway for clinical trial. Expected completion of patient accrual in March of 2017, and median primary end points have not been achieved to date. Patient outcomes currently available suggest that the treatments have modest activity in metastatic breast cancer.

Submission Type: Descriptive Report

Session-Board Number: 2-356

Poster Title: Evaluation of switching from charge on dispense to charge on administration on pharmacy revenue

Primary Author: Hiten Patel, Texas Southern University College of Pharmacy and Health Sciences, Texas; **Email:** hitenpatel02@gmail.com

Additional Author (s):
Pei Jen Lin
Anthony Colavecchia

Purpose: As healthcare institutions adopt barcode medication administration (BCMA) technology, medication charging models often change from charge on dispense (COD) to charge on administration (COA). When changing from COD to COA, hospital pharmacies may see a decrease in revenue due to medications not having barcodes, nurses not scanning medications upon administration, and other factors. No published literature exists regarding the impact of switching from COD to COA and its effect on pharmacy revenue. The purpose of this study was to evaluate the immediate financial impact of transitioning from COD to COA one-month after BCMA go-live.

Methods: The investigational review board waived this quasi-experimental quality improvement project. Medication charge records were collected in June 2015 and June 2016 to compare the transition from COD to COA. The compiled medications were analyzed based on inpatient charge amount, outpatient charge amount, and total charge amounts for each respective year. All medications were assigned their corresponding American Hospital Formulary Service Pharmacologic-Therapeutic Classification code and therapeutic class in order to identify high cost medication usage. The number for total charge quantity, inpatient charge quantity and outpatient charge quantity was determined. We hypothesized a 5 to 10 percent decrease in pharmacy revenue after converting to COA from COD. The primary endpoint of the study was to determine the percent change in pharmacy charges one-month post go-live in comparison to the same month the previous year.

Results: All medication charges from the hospital during the months of June 2015 and June 2016 were analyzed, which included a total of 4584 unique medications. The total number of unique medications charged in June 2015 was 2417 compared to the total number of medications recorded in June 2016 which was 2167. Total charge amount increased by 16.3% from June 2015 to June 2016. Inpatient and outpatient medications charge amount increased by 12.9% and 21.9% respectively from 2015 to 2016.

Conclusion: After transitioning from COD to COA, an increase in pharmacy charges was observed one-month post go-live without controlling for other factors. This macro assessment revealed the opposite of the hypothesis made by the study team. The increase in pharmacy revenue is multifactorial and could be due to more patient days, increase in medication costs, and increased capture rates. Future studies should control for these variables in order to isolate the changes in revenue.

Poster Title: Characteristics of patients enrolled in a medication therapy management program for pediatric African-Americans with asthma

Primary Author: Jennifer Pospisil, Texas Southern University College of Pharmacy and Health Sciences, Texas; **Email:** jennifermpospisil@gmail.com

Additional Author (s):
Kim Nguyen
Tu Nuyen
Raven Askew

Purpose: African-American children are 7 times more likely to die of asthma and three times more likely to be admitted to the hospital for asthma than non-Hispanic white children. Uncontrolled asthma leads to increased exacerbations, hospitalizations, impaired quality of life, and even death. The purpose of this study is to discuss the characteristics of the patients who participated in the medication therapy management (MTM) services, provided by pharmacists, to increase the level of control of asthma.

Methods: The study design is a pre-post study where each patient serves as his or her own control. Participants enrolled provided signed consent from their parents or legal guardians and were African-American children between the ages of 4-17, who have Texas Medicaid and uncontrolled asthma. For the purpose of this study, uncontrolled asthma was defined as patients who filled a prescription for an oral corticosteroid, had an asthma-related emergency room visit or hospitalization, or excessive fills of their rescue inhaler. A total of 150 participants were initially enrolled and received in home MTM services provided by a pharmacist. Pharmacists who provided the MTM services received specialized asthma MTM training prior to meeting with participants. Each pharmacist was provided a protocol to use for each visit where asthma knowledge, severity and level of control were assessed as well as drug therapy and medication adherence.

Results: Of the 150 patients who enrolled, 130 (87 percent) were between the ages of 4 to 11 years old and 20 (13 percent) were between 12 to 17 years old. The average asthma knowledge test score was a 7 out of 15 possible points, with 65 of the participants scoring above 7. The average medication adherence score was 8 out of a possible 15 points, with 71 participants having a score greater than 8. Overall, 47 percent of participants adhered to their medication and 43percent had average asthma knowledge. Asthma control test were given and scored based on patient ages. For the age group of 4 to 11 years old, the average control test score was 19 out of 25 points with 54 percent of the age group scoring above 19. For the age group of 12 to 17, the average control test score was 17 out of 25 points with 55 percent of the age group scoring above 17. 54 percent of the participants classified as well controlled, 37 percent were not well controlled and 9 percent poorly controlled.

Conclusion: This study provides demographics of pediatric African-American asthma patients willing to participate in MTM services provided by pharmacist. It also provides evidence of the continuing need for education about asthma and medication adherence for the population of pediatric African-American asthmatic patients.

Poster Title: Assess the incidence of pablociclib-related toxicities at a cancer center

Primary Author: Zahra Naini, Texas Southern University- College of Pharmacy and Health Sciences, Texas; **Email:** zahra.naini@gmail.com

Additional Author (s):
Bincy Thankachan
Mohamed Hindi
Rodney Hunter

Purpose: About 1 in every 8 women in the United States will develop breast cancer in their lifetime and it is the leading cancer in women. In February 2015, the FDA approved Ibrance (palbociclib), a cyclin-dependant kinase (CDK) 4 and 6 inhibitor, to be used in combination with letrozole, an aromatase inhibitor, for treatment of metastatic breast cancer. Despite significant success in treatment, a number of toxicities were recorded. The primary outcome of this study is to assess and document the toxicities related to palbociclib since the approval of this drug at a cancer center in Texas.

Methods: This is an open-label study conducted since February 2015 in a cancer center in Texas. The primary outcome is to assess and document the number of incidence of Palbociclib-related toxicities since the approval of this drug. The study includes pre-menopausal, peri-menopausal and post-menopausal women older than 18 years of age with estrogen receptor (ER)-positive metastatic breast cancer. The clinical pharmacist in the research team identified the patients with the above inclusion criteria and determined the study arms. The first arm received oral palbociclib 125 mg once daily for 21 days (followed by 7 days off treatment) plus subcutaneous goserelin 3.6 mg every 28 days, and a loading dose of intramuscular fulvestrant 500 mg once daily on days 1, 15, and 29 followed by a maintenance dose of fulvestrant 500 mg once monthly. The second arm received oral palbociclib 125 mg once daily for 21 days (followed by 7 days off treatment) plus a loading dose of fulvesterant 500 mg once daily on days 1, 15 and 29 followed by a maintenance dose of fulvestrant 500 mg once monthly, and the third arm received oral palbociclib 125 mg once daily for 21 days (followed by 7 days off treatment) plus continuous oral letrozole 2.5 mg daily. This study was approved through the hospital's institutional review board.

Results: A total of 17 patients participated in the study but only 16 were analyzed due to one death, which was not related to palbociclib treatment. The most common adverse effects associated with palbociclib were anemia (88 percent), leukopenia (88 percent), and neutropenia (35 percent). Neutrophil counts below median at baseline were associated with a higher chance of developing neutropenia later in the course of treatment with palbociclib. The other side effects noted were mucositis, alopecia, fatigue, and gastrointestinal complications. The palbociclib dose was reduced in 4 out of 17 patients (24 percent) due to adverse effects.

Conclusion: The main adverse effects associated with palbociclib in treating estrogen receptor (ER)-positive metastatic breast cancer were anemia, leukopenia, and neutropenia. The palbociclib-related adverse effects were managed by dose reduction.

Poster Title: Initiation and optimization of drug therapy in patients with dyslipidemia at a local charity clinic

Primary Author: Blanca Guerra, Texas Southern Universtiy College of Pharmacy and Health Sciences, Texas; **Email:** blanca22guerra@yahoo.com

Additional Author (s):
Sonia Paz
Brenda Opande
Adlia Ebeid

Purpose: Practical approach to statin therapy has been the main prescribed treatment in the United States after the 2013 ACC/AHA Guidelines on the Treatment of Blood Cholesterol to Reduce Atherosclerotic Cardiovascular Risk in Adults (2013 cholesterol guidelines) were published. Based on the application of new cholesterol guidelines to a population-based sample study, the number of adults receiving or eligible to receive a statin should have increased. The objective of this study was to analyze prescribing habits in a non-profit, urban, low-income charity clinic and to determine the appropriateness of statin therapy initiation and optimization based on the 2013 cholesterol guidelines.

Methods: This retrospective, observational study evaluated patients who had a compelling indication or who were in a statin benefit group based on the 2013 cholesterol guidelines from January 01, 2014 to May 31, 2016. A total of 1285 patient's were identified, from which random samples of 119 patients were chosen. Structure query language queries were used to randomly select patients. Patient profiles were individually analyzed and pertinent information was extracted into an excel spreadsheet. Inclusion criteria were limited to patients who had at least 2 physician visits, age greater than 21 years old, diagnosis codes that included: dyslipidemia, clinical atherosclerotic cardiovascular disease, diabetes, hypertension, obesity, smoking status, and lipid panel lab. Exclusion criteria included, patients who lacked a lipid panel lab and patient's who were not in a statin benefit group after the 10-year atherosclerotic cardiovascular disease (ASCVD) risk was calculated. The 10-year ASCVD risk was calculated based on the patient's earliest visit and lipid panel lab within the study period. The primary outcome was the

proportion of patients who were appropriately initiated and optimized on statin therapy or other appropriate therapy as per 2013 cholesterol guidelines.

Results: After the selection of 119 random patients, seven patients did not meet the criteria for the study and 13 patients did not meet criteria for one of the four statin benefit groups after the ASCVD risk was calculated. The median age was 55; 63% (n=71) of patients were female, 37% (n=41) were male. Race distribution was as follow: Hispanic 52% (n=58), White 28% (n=31), African American 16% (n=18) and Asian 4% (n=5). The patients who were prescribed appropriate therapy, optimized to suitable therapy and/or who were council on lifestyle modification was 45% (n=45). The majority of patients, 55% (n=54), did not have appropriate optimized therapy after the 2013 cholesterol guidelines, were inappropriately maintained on an agent other than a statin, and/or had inappropriate conversion between low, moderate or high-intensity.

Conclusion: Patients at this local charity clinic were found to be appropriately initiated and optimized on proper therapy 45% of the time based on the 2013 ACC/AHA Guidelines on the Treatment of Blood Cholesterol to Reduce Atherosclerotic Cardiovascular Risk in Adults. The prescribing habits therefore should mirror the predicted increase in the use of statin therapy after the 2013 cholesterol guidelines were published. As a result of the study, perhaps an in-service or discussion with providers to discuss 2013 cholesterol guidelines versus observed prescribing trends would provide better outcomes.

Poster Title: Impact of insulin detemir administration time on glycemic excursion rates

Primary Author: Sydney Kutter, Texas Tech University Health Sciences Center School of Pharmacy, Texas; **Email:** sydney.kutter@ttuhsc.edu

Additional Author (s):
Jennifer Grelle
Chris Tawwater
Megan Geurds

Purpose: The 2016 ADA Standards of Care state insulin is the preferred strategy for glycemic control for inpatients. Hypoglycemia, the major side effect of insulin, is associated with mortality and increased hospital length of stay. The most common long-acting insulin agents used are detemir and glargine. Glargine has a 24-hour duration of action with sparse data suggesting AM administration may result in less hypoglycemia. In contrast, detemir has a shorter duration that may lead to inferior glucose control and hypoglycemia. The purpose of this study was to evaluate hypoglycemic episodes between subjects administered detemir in the morning, evening, or twice daily.

Methods: A retrospective review of medical records was used to identify subjects admitted between January 1, 2014 and December 31, 2015 after being initiated on detemir > 48 hours. The study population included patients 18-89 years of age with a length of stay > 48 hours. Patients were excluded if they were prisoners or wards of the state, pregnant females, received continuous infusion insulin, or if the schedule of insulin was changed during their hospital stay. One thousand fifty-two patients were screened and 695 were excluded. Three hundred fifty-seven patients were included in the study, of which 71 were in the AM group, 158 in the PM/HS group, and 128 in the BID group. The primary outcome of this study was the number of patient days of hypoglycemia per patient stay. Secondary outcomes included the number of patients who experienced hypoglycemia, hypoglycemic episodes per patient stay, rates of severe hypoglycemia, episodes of refractory hypoglycemia, maximum and minimum blood glucose level each hospital day, and rates of hyperglycemia.

Results: The primary objective of patient days of hypoglycemia per hospital stay was reduced in the AM versus PM group and statistically significant after a post-hoc chi-square test with a Bonferroni adjustment (7.9 vs. 11.9%, p = 0.008). The BID group demonstrated a trend of less hypoglycemic days when compared to the PM group, though this result was not statistically significant after Bonferroni adjustment (9.1% vs. 11.9%, p = 0.03). The number of patients who were hypoglycemic was 35%, 47.5 %, and 39.8% in the AM, PM, and BID group, respectively (p = 0.173). Severe hypoglycemia was noted in 7%, 5.7%, and 5.4% in the AM, PM, and BID groups respectively (p = 0.896). The average daily minimum, maximum, and variation of blood glucose appeared to be lowest in the PM versus AM versus BID groups, respectively. The percentage of blood glucose readings defined as hypoglycemia per the 2016 ADA guidelines (BG < 70 mg/dL) were highest in the PM group, with the AM group demonstrating the lowest rate of hypoglycemia. The percentage of blood glucose readings defined as hyperglycemia per the ADA guidelines (BG>180 mg/dL) were lowest in the PM group and highest in the BID group.

Conclusion: The primary outcome of hypoglycemic days per patient stay was lower in the AM versus BID versus PM group, respectively. Patients in the AM group also experienced less overall episodes of hypoglycemia. Overall glucose variability was the lowest in the PM group, though this result appears to be driven mainly by a decreased rate of hyperglycemia and an increased rate of hypoglycemia in the PM group. During hospitalization, administration of insulin detemir in the morning may be preferential to avoid episodes of hypoglycemia.

Poster Title: To quantify the teaching component and activities of residents in an academic-affiliated residency program.

Primary Author: Darshil Dodhiya, Texas Tech University Health Sciences Center School of Pharmacy, Texas; **Email:** darshil.dodhiya@ttuhsc.edu

Additional Author (s):
Yasameen Nazemi
Steven Pass

Purpose: Residents provide an invaluable skill and resource for teaching and precepting pharmacy students. The purpose of this project was to evaluate and quantify the teaching involvement of Texas Tech Health Sciences Center School of Pharmacy (TTUHSC SOP) affiliated residents.

Methods: Both PGY1 and PGY2 residents completed an annual self-evaluation report which summarized the activities they completed or participated in during the residency program. The annual report included information that was subdivided into 4 main categories: Teaching, Precepting, Facilitating, and Student-Related Professional activities. We pooled the data and analyzed the amount each resident invested in those categories by campus (Dallas, Lubbock, Amarillo, and Abilene) and by year (2012-2015). Data was also collected regarding the number of residents who completed the teaching certification program.

Results: In between 2012-2016, 107 total residents went through the TTUHSC SOP residency program for which we were able to obtain 104 out of 107 annual reports that summarized the resident activities during the year. Based on the annual reports, 104 residents provided 168 classroom lectures, facilitated 2237 discussion groups and labs, precepted 151 intermediate pharmacy practice experience (IPPE) rotations, precepted 48 advanced pharmacy practice experience (APPE) rotations, and precepted a total of 359 students across 4 years. Additionally, 72 out of the 104 residents completed the teaching certificate offered by TTUHSC SOP (67%). Across the 4 years, the total number of student-related professional activities was 240.

Conclusion: Due to essential role that residents play as educators, we sought to identify the extent of teaching involvement of residents quantitatively. The results of the annual reports reveal that a noteworthy amount of pharmacy student's learning is taught by residents. The development of residents as educators is an important element of the ASHP residency accreditation standards. Based on these standards, residents are expected to progress through the four roles of precepting which include: direct instruction, modeling, coaching, and facilitation. The results from the annual reports show that the TTUHSC SOP residents are fulfilling and excelling in each of those responsibilities.

Poster Title: Career pathways following the PGY1/ PGY2 TTUHSC residency programs

Primary Author: Yasameen Nazemi, Texas Tech University Health Sciences Center School of Pharmacy, Texas; **Email:** yasameen.nazemi@ttuhsc.edu

Additional Author (s):
Darshil Dodhiya
Steven Pass

Purpose: Securing a first job after completion of a residency is a concern for P4 students as they consider a possible future as a resident. It is also a concern for current residents who have invested time and money to further their education. The purpose of this review was to evaluate the first jobs or career path chosen by residents upon completion of either a PGY1 or PGY 2 at Texas Tech University Health Sciences Center School of Pharmacy (TTUHSC SOP) within the last 4 years.

Methods: Information regarding PGY1 and PGY2 post-residency career paths and first jobs from the last 4 years was obtained from school administration records, the residency director, and the Tech Times. The Tech Times is a newsletter that is published quarterly for the graduates of TTUHSC SOP residency program; it contains the future plans of the residents. The Tech Times only contained information for the years 2014-2015 and 2015-2016. Information for residents for 2012-2013 and 2013-2014 was obtained via other resources such as administration records and information provided by the PGY2 residency director of TTUHSC SOP.

Results: Across 4 years, 63 residents completed a PGY1 and 44 residents completed a PGY2 at TTUHSC SOP. Out of the 63 PGY1 residents, 5 obtained an academic position, 20 obtained a clinical position, 35 went on to complete a PGY2, and 3 residents were categorized as miscellaneous. Out of the 44 PGY2 residents, 8 obtained academic positions, 33 obtained clinical positions, and 3 residents were categorized as miscellaneous.

Conclusion: Career planning is an essential part of the final year of PharmD training. Many P4 students spend the last year of pharmacy school trying to decide if they want to further their education and training by pursuing a residency. Students make this decision based on a number of factors; one of these factors includes the ease of employment post-residency. Based on the results, the majority of PGY2 residents were able to secure a clinical position. Many PGY1 residents were able to secure a clinical position just after one year of residency, while the majority went on to complete a PGY2.

Poster Title: Retrospective review evaluating dosing strategies of three-factor prothrombin complex concentrate (3F-PCC) in the reversal of factor Xa inhibitors

Primary Author: Lauren Yancy, Texas Tech University Health Sciences Center School of Pharmacy, Texas; **Email:** lauren.hodges@ttuhsc.edu

Additional Author (s):
Kristina Carter
Stephen Rush
Patricia Newcomb
Kaysey Cloud

Purpose: Factor Xa inhibitors are becoming the favorable choice for prevention of thrombosis in patients with atrial fibrillation and venous thromboembolism. However, the lack of a direct antidote to these agents adds risk to their utility. Guided by limited available literature, our institution (720-bed, level-2 trauma, community hospital) developed a protocol for management of emergent anticoagulation reversal secondary to factor Xa inhibitors. The protocol includes a dose of 3F-PCC at 35 units per kilogram. Our retrospective review investigates two dosing strategies and their effects on prothrombin time, international normalized ratio, anti-factor Xa, the development of new venous thromboembolism and in-hospital mortality.

Methods: Retrospective data was gathered for all patients who received 3F-PCC between August 2013 and August 2016. A chart review was performed for patients greater than or equal to 18 years of age who received 3F-PCC for the reversal of factor Xa inhibitors including: apixaban, rivaroxaban and edoxaban. Data collection included age, sex, creatinine clearance (CrCl), prescribed anticoagulant, indication for anticoagulation, indication for reversal, dose of 3F-PCC (units per kilogram), supplementary doses of 3F-PCC, adjunctive therapy (fresh frozen plasma, platelets, activated factor VII, packed red blood cells), surgery type/length and associated blood loss, baseline prothrombin time (PT), international normalized ratio (INR), anti-factor Xa (anti-Xa) plus four serial follow up levels for each, in-hospital mortality, development of new venous thromboembolism (VTE), and bleeding enlargement confirmed by computed tomography. Indications for bleeding were categorized as follows: spontaneous

intracerebral hemorrhage (ICH), traumatic ICH, extracranial hemorrhage, traumatic injury or emergent surgery for non-bleeding/non-traumatic reasons. ICH was defined as subdural hematoma, subarachnoid hematoma or intraparenchymal occurring spontaneously or from traumatic injury. Extracranial bleeding was that which occurred spontaneously outside of the brain. Variation in dosage was studied by organizing patients into two distinct groups: those who received less than 35 units per kilogram of 3F-PCC ("low-dose") and those who received greater than or equal to 35 units per kilogram ("high-dose"). This study was submitted to the Institutional Review Board for approval.

Results: We identified 285 patients who received 3F-PCC between August 2013 and August 2016. Of these 79 patients were receiving factor Xa inhibitors as their anticoagulation therapy (46 on rivaroxaban, 32 on apixaban and 1 on edoxaban). Baseline characteristics included a mean age of 77 years, 46% male, mean CrCl of 51 mL/min. Out of the 79 patients, 16% had spontaneous ICH (N=13), 32% had traumatic ICH (N=25), 28% had extracranial hemorrhages (N=22), 10% had hemorrhages from traumatic injury (N=8), and 14% of patients required emergent surgery for other reasons (N=11). A total of 49 patients received the "low dose" and 30 patients received "high dose." The "low dose" group had a larger decrease in both PT and INR from baseline to first follow up lab (-4.8 vs. -2.5 seconds, r=-0.138, p=0.335 and -0.63 vs. -0.27, r=-0.21, p=0.389, respectively) while the mean change in anti-Xa from baseline to first follow up lab for the same group was less (-0.27 vs. -0.46 IU, r=0.209, p=0.215). Both the rate of new VTE development and mortality were lower in the "low dose" group (4.1% vs. 16.7%, OR =1.42, 95% CI 0.26 to 7.87 and 10.2% vs. 16.7%, OR=1.76, 95% CI 0.26 to 7.87), respectively.

Conclusion: Among all calculated results from our study, the one of most interest is the association of "high dose" 3F-PCC with a higher mortality rate. The odds ratio of death in patients receiving the higher dose was 1.76. While this number did not meet statistical significance, clinical significance may still exist. Further investigation is needed to determine why higher doses were chosen and the possibility that underlying indications for higher dosed reversal are inherently correlated to worse prognoses. If the higher doses were truly chosen at random then larger prospective trials are needed to determine if lower doses have better outcomes.

Poster Title: Comparative-effectiveness of ceftaroline and daptomycin as first-line therapy for patients with diabetic foot infection in the United States Veterans Health Care System

Primary Author: Taylor Dean, The University of Texas at Austin, Texas; **Email:** taylor.dean2015@utexas.edu

Additional Author (s):
Kirk Evoy
Rachel Britt
Marilyn Mootz
Christopher Frei

Purpose: Up to 25% of patients with diabetes experience a diabetic foot infection (DFI) in their lifetime. DFI are often difficult to treat, both due to the pathology of diabetes and the nature of the infecting organisms, as many DFI are polymicrobial and the incidence of resistant infections such as methicillin-resistant Staphylococcus aureus (MRSA) are increasingly common. However, evidence supporting specific drugs in the treatment of DFI is lacking. This study compared hospital readmission and mortality rates among patients receiving ceftaroline fosamil or daptomycin for DFI to compare the clinical effectiveness of these potential treatment options.

Methods: This was a retrospective, cohort, comparative--effectiveness study of adults (age 18+ years), admitted to hospitals in the United States Veterans Health Care System, with diabetic foot infections (by ICD9 codes), between 10/1/10--9/30/14, and who received ceftaroline or daptomycin as first--line therapy within 14 days of admission. Patients who received both study drugs were excluded. Chi--square, Fisher's exact, and Wilcoxon rank sum tests were used to compare baseline characteristics. Multivariable logistic regression models with Hispanic race, prior hospitalization, dyslipidemia, and Charlson comorbidity score as covariates were used to compare differences in hospital readmission and patient mortality.

Results: A total of 223 patients were included (ceftaroline=71 and daptomycin=152). At baseline, ceftaroline patients were more likely to be Hispanic (18% vs. 6%, p=0.0043) and to have been hospitalized in the past 90 days (34% vs. 19%, p=0.0161). Median (25th--75th percentile) time from hospital admission to study drug initiation was 0 (0--1) days for

ceftaroline and 1 (0--1) day for daptomycin. Unadjusted hospital readmission rates for ceftaroline versus daptomycin were: 30--day (30% vs. 40%), 60--day (31% vs. 47%), and 90--day (34% vs. 49%). Unadjusted mortality rates were: 30-day (0% vs. 4%), 60--day (0% vs. 7%), and 90--day (1% vs. 8%). In multivariable models, ceftaroline patients were less likely than daptomycin patients to experience 60--day hospital readmission (OR=0.46, 95%CI=0.24--0.86), 90--day hospital readmission (0.46, 0.25--0.85), and 90--day mortality (0.14, 0.01--0.77). Comparisons of 30--day hospital readmission and 30/60--day mortality were not statistically significant. Adverse effects were also similar, with no difference among the two cohorts, though a non-significant trend towards higher incidence of leukocytosis (WBC of at least 15,000) in patients treated with daptomycin was observed (16% versus 7%, $p < 0.0875$).

Conclusion: In this population, ceftaroline was associated with lower 60/90--day hospital readmission and 90--day mortality, as compared to daptomycin, when used as first--line therapy for diabetic foot infection. Larger samples sizes are needed to compare these study endpoints at 30 and 60 days.

Poster Title: Dronabinol for the treatment of veterans with chronic pain: a retrospective case series

Primary Author: Aanika Das, The University of Texas at Austin College of Pharmacy, Texas; **Email:** aanika.das@gmail.com

Additional Author (s):
Emily Davies
Justine Boge
Margaux Salas

Purpose: Opioid therapy continues to be the most common pharmacologic treatment for most chronic pain diagnoses. Unfortunately, chronic opioid therapy involves many risks and controversial benefits. Per the Centers for Disease Control and Prevention, in 2014, 61% of drug overdose deaths in the US involved some type of opioid, including heroin. It has been shown that receiving prescription opioids is associated with increased risk of adverse clinical outcomes, including opioid-related accidents and overdoses, which is particularly elevated in veterans with PTSD. Alternatives and adjuvants to opioid pain management strategies are necessary. Growing evidence suggests that cannabinoids may be useful in the setting of chronic pain. Cannabinoids affect the endogenous endocannabinoid system through cannabinoid receptors 1 and 2 (CB1, CB2). CB1 is found in high densities in the central nervous system, and CB2 is found primarily in the periphery, including the immune system. Activation of these receptors, especially CB1, can cause psychological effects as well as analgesia, muscle relaxation, and appetite stimulation. To date, more than 60 active compounds have been identified from cannabis, including (-)trans-delta-9-tetrahydrocannabinol, which has been reported to have analgesic properties. Dronabinol is a synthetic form of delta-9-tetrahydrocannabinol, activating CB1 and CB2 receptors. Dronabinol has FDA-labeled indications to include appetite stimulation in AIDS patients and chemotherapy-induced nausea and vomiting.

Three veterans with chronic pain prescribed chronic opioid therapy were initiated on dronabinol for opioid weaning. Patients' electronic medical records were retrospectively reviewed over a nine-month period (December 2015-August 2016). Data collected included patient demographics, opioid regimen throughout dronabinol therapy, morphine equivalent

daily dose (MEDD) at dronabinol initiation and throughout dronabinol therapy, and Defense and Veterans Pain Rating Scale scores. Data were collected at the initiation of dronabinol therapy, at 3 months, at 6 months, and at 9 months post-initiation.

The average age of the three veterans (one female, two males) was 45 years. All three patients were prior enlisted. The three veterans were prescribed an average of 263 MEDD prior to dronabinol initiation. To date, dronabinol treatment has shown an average decrease of 182 MEDD, or 72% decrease in MEDD. Patient 1's pain score decreased from 10/10 to 9/10. Patient 2's pain score increased by one point from 6/10 to 7/10. It should be noted that during this time, patient 2 was completely weaned off opioid therapy. Patient 3's pain score decreased two points from 9/10 to 7/10.

Dronabinol may prove to be an effective analgesic, allowing for reduction or potential elimination of chronic opioid requirements in patients with chronic pain diagnoses. Dronabinol may represent a safer and possibly more effective option than opioids for chronic pain. We anticipate these veterans' MEDDs to continue to decrease as they are weaned from high-dose opioids and as dronabinol therapy is optimized. Dronabinol has the potential to reduce the number of pain medications a patient needs for optimal pain management.

Poster Title: Development of a prediction tool for recurrent Clostridium difficile infection in a veteran population

Primary Author: Sarah Rumbellow, The University of Texas at Austin College of Pharmacy, Texas; **Email:** sarumbellow@gmail.com

Additional Author (s):
Jacqueline Argamany
Stefan Allen
Kelly Reveles

Purpose: Clostridium difficile infection (CDI) is the main cause of bacterial infectious diarrhea in nosocomial settings. Not only does recurrent CDI heavily burden patients by increasing morbidity and mortality and diminishing quality of life, it is also costly. Prior clinical trials identified several patient-specific factors that increase risk for recurrent CDI; however, clinicians lack guidance on how to use these risk factors to improve patient care. The objective of this study was to derive and validate a clinical prediction rule for CDI recurrence, in hopes of improving health outcomes and quality of life of patients with CDI.

Methods: This was a retrospective cohort study of CDI patients receiving care at any of the approximately 150 Veterans Health Administration (VHA) hospitals and 800 VHA clinics in the United States from October 1, 2002 through June 30, 2012. Patients 18-89 years old with an International Classification of Diseases, 9th Revision Clinical Modification (ICD-9-CM) code for CDI (008.45) were included. Patients were excluded if they had an ICD-9-CM code for CDI in the previous year or if they died within 60 days of treatment discontinuation for initial CDI episode. A CDI 60-day recurrence prediction rule was derived in one-third of the cohort, using backward stepwise logistic regression. Of 42 variables tested, factors significant at $p < 0.05$ in the model were assigned an integer score proportional to the beta-coefficient. The model was validated in the derivation cohort and in a validation cohort, representing the remaining two-thirds of the cohort, using the area under the receiver-operating-characteristic curve (AUROC) and correlation.

Results: The prediction rule was developed using a total of 48,269 patients with 16,130 in the derivation cohort and 32,139 in the validation cohort. Variables included in the prediction rule, and assigned an integer score were chronic obstructive pulmonary disease (1 point), renal disease (1 point), dyslipidemia (1 point), white blood cell count ≥ 15,000 cells/ml (2 points), prior antibiotics (3 points), white race (3 points), principal CDI (5 points), and community-onset, healthcare facility-associated CDI (7 points), for a total of 23 possible points. The recurrence risk for each score ranged from 13% (0 points) to 52% (23 points). The risk score was strongly correlated with recurrence (R2=0.93). Patients were split into low (scores 0-7), medium (8-15), and high (16-23) risk groups. Overall recurrence rates in each group were as follows: low risk (17%), medium risk (26%), and high risk (36%). Rates of recurrence were similar between derivation, validation, and overall cohorts.

Conclusion: Increasing risk score was strongly correlated with CDI recurrence. This clinical prediction rule may be utilized by providers in choosing appropriate preventive therapies in CDI patients based on recurrence risk.

Poster Title: Assessment of discharge antimicrobial selection for patients presenting with urinary tract infection symptoms in two pediatric emergency departments

Primary Author: Nicole Wilson, The University of Texas at Austin College of Pharmacy, Texas; **Email:** nicolewilson@utexas.edu

Additional Author (s):
Sarah Kubes
Letitia Delaine

Purpose: Antimicrobial selection and prescribing in pediatric patients presenting to emergency departments with a concern for a urinary tract infection is often a challenge. Most patients are treated empirically based on local susceptibilities, but good antimicrobial stewardship practice should be utilized to maximize patient outcomes. At the Children's Hospital of San Antonio, isolate results were compared with discharge medication to analyze appropriateness of the antibiotic selected empirically, as well as determine if narrower-spectrum antibiotics could have been used.

Methods: This was an institutional review board exempt, retrospective study assessing urine isolates and susceptibilities that were obtained from the Emergency Department in the Children's Hospital of San Antonio and the Children's Emergency Department at Westover Hills during the month of June 2016. Unique isolates from urine cultures were included for all patients seen at either emergency department in outpatient visits who were up to 18 years of age at the time of presentation. Additionally, all negative urine cultures were included to more accurately assess prescribing practices. Discharge prescription information (drug, dose, dosing interval and duration), patient weight, isolate susceptibilities and patient allergies were also collected. Only isolates with 30,000 or more colony forming units were considered appropriate to treat. Negative cultures that were treated were considered inappropriate. Appropriateness of drug selection was defined as the most narrow spectrum agent available to treat the subsequently isolated bug.

Results: A total of 113 unique isolates were identified. Of the isolates, 24 percent (n equals 27) were treated with the appropriate drug, dose and duration, or antimicrobials were appropriately withheld. Of those patients discharged with an antimicrobial, the appropriate drug, dose, and duration were prescribed 1.35 percent of the time (1 time out of 74). The appropriate antimicrobial was prescribed or appropriately withheld 30 percent of the time. Of those who were discharged with an antimicrobial, appropriate dose or duration were seen 74 percent and 32 percent of the time, respectively. The most common drug prescribed was cefdinir (48 percent, n equals 54), followed by trimethoprim-sulfamethoxazole (n equals 7) and cephalexin (n equals 5). No drug was prescribed for 39 patients (34.5 percent). Of the isolates, 63.7 percent were cefazolin sensitive and 31.9 percent were ampicillin sensitive. Additionally, of the patients treated with cefdinir, isolates were susceptible to a first generation cephalosporin 77.8 percent of the time (n equals 42). The most common urine isolate was Escherichia coli (n equals 67), with Staphylococcus sp. being the second most common (n equals 13), which was likely a contaminant. The average duration of therapy was 9.6 days.

Conclusion: A small portion of our patient population was discharged on appropriate therapy. In most instances, patients were prescribed antimicrobials that were too broad. In the age of antimicrobial stewardship, it is imperative to define local resistance patterns and develop a protocol-driven consensus on how to best empirically treat pediatric patients for urinary tract infections.

Poster Title: Transitions of care medication trends in pediatric patients at a Central Texas children's hospital

Primary Author: Natalia Malesa, The University of Texas at Austin College of Pharmacy, Texas;
Email: nmalesa@gmail.com

Additional Author (s):
Brandy McGinnis
Thanhhao Ngo

Purpose: Patients are often discharged with prescriptions for medications that are integral to continuity of care. Transitions of care services provided by pharmacists may improve patient safety and health literacy through medication reconciliation and education. There is limited data on the role of pharmacy services during transitions of care in the pediatric setting. The objective of this study is to determine whether any notable trends exist in patients' prescribed medications during transitions of care at Dell Children's Medical Center of Central Texas (DCMCCT). This study may help to identify opportunities for pharmacist-led medication reconciliation and discharge counseling in the pediatric population.

Methods: A retrospective chart review was conducted of patients discharged from DCMCCT between January 1 – 31, 2016 and June 24 – July 27, 2016. Patients were identified via a query in Cerner PowerChart. Clinical information related to the patient's discharge was collected by reviewing the patient's electronic medical record in PowerChart. Patient characteristics that were analyzed included the number of patients who were discharged with prescriptions, how many prescriptions they received, nursing units from which they were discharged, date and time of discharges, and whether or not the patient was readmitted within 30 days. Discharge medication characteristics that were analyzed included the number of prescriptions written, classes of medications prescribed, and whether or not the medications were antimicrobials or over-the-counter. All patients who were discharged from DCMCCT during the specified time periods were included in the study. Data were analyzed in Microsoft Excel using descriptive statistics.

Results: In January 2016, 1193 patients were discharged, 471 (39.5 pct.) of whom were discharged with prescriptions. In July 2016, 899 patients were discharged, 393 (43.7 pct.) with prescriptions. In both cohorts, most patients with prescriptions were discharged between 8:00 am and 5:00 pm (Jan: 75.6 pct.; Jul: 74.8 pct.). The greatest numbers of patients with prescriptions were discharged from the respiratory care unit in January (24.0 pct.) and the neurology/epilepsy monitoring unit in July (25.7 pct.). Both units also care for internal medicine patients. A total of 876 discharge prescriptions were written in January and 802 in July. Most patients being discharged with prescriptions received one to three prescriptions (Jan: 90.4 pct.; Jul: 87.3 pct.). The most commonly prescribed medications in January were albuterol (11.9 pct.), ibuprofen (11.1 pct.), and ondansetron (6.7 pct.), while those most commonly prescribed in July were ibuprofen (7.9 pct.), hydrocodone/acetaminophen (7.7 pct.), and diazepam (6.0 pct.). Similar numbers of prescriptions for over-the-counter medications (Jan: 34.5 pct.; Jul: 35.4 pct.) and antimicrobials (Jan: 7.4 pct.; Jul: 7.2 pct.) were written for both cohorts. There were 65 readmissions in January and 61 in July. Data for readmitted patients were similar to those from their respective cohorts.

Conclusion: By identifying the time of day and units from which patients are most often discharged with prescriptions, pediatric institutional pharmacies may be better able to repurpose pharmacy staff for medication reconciliation and discharge counseling efforts. Additionally, identifying medications most likely to be prescribed at discharge may facilitate the development of institution-specific patient education materials. It is recommended that pediatric institutional pharmacies wishing to develop transitions of care services collect and evaluate data on medication trends in order to optimize resources and more effectively care for patients at the point of discharge.

Poster Title: Assessing the impact of familialism on immunization practices in predominately Spanish-speaking Hispanic community health centers along the US-Mexico border

Primary Author: Joel Isais, The University of Texas at Austin College of Pharmacy, Texas; **Email:** jisais@utexas.edu

Additional Author (s):
Michelle Aguirre

Purpose: People in the United States continue to get diseases that are vaccine preventable. A portion of these cases can be attributed to people not getting immunized against vaccine preventable diseases in the first place. The purpose of this study was to determine the impact of familial influence on vaccination practices in respondents as they transition from childhood into adulthood, to explore cultural beliefs that would adversely affect the probability of receiving recommended vaccines, and to determine if a Hispanic community primarily looks to family members instead of healthcare professionals when it comes to making decisions on vaccinations.

Methods: This is an ongoing prospective observational study of patients who receive care at local community health centers. Inclusion criteria included men and women at least 18 years of age who were present at the community health centers. Participants were randomly selected and asked to complete a two-part survey electronically. The first survey was a 10-question demographic survey used to determine several characteristics such as education, age, race/ethnicity, and socioeconomic status. A second survey composed of 46 questions assessed a respondent's early childhood experience with the flu vaccine while growing up with his/her family as well as the respondent's current views and practices concerning the flu vaccine. In addition, the second survey included a validated familialism scale. Upon consultation with a psychometric specialist, the survey tools were adapted to meet the appropriate literacy level of no more than 9th grade level. Likewise, the surveys were created to be culturally and linguistically appropriate for the US-Mexico border. Participants had the option of completing the survey in either English or Spanish. Trained personnel were present to administer the survey and assist participants if they did not understand any of the questions. This ongoing study was exempt by the University of Texas at El Paso institutional review board.

Results: A total of thirty-one participants have completed the two-part survey (English n = 16, Spanish n = 15). The majority of respondents were women (22/31 = 71 percent), had an average age of 51, identified as Hispanic/Latino (29/31 = 94 percent), and lived in a home in which the primary language spoken is Spanish (22/31 = 71 percent).

The preliminary results have identified that a majority of respondents have received the flu vaccine in the past 12 months (18/31 = 58 percent). One observed correlation surfaced during this early stage of data analysis. Respondents who answered that their family had negative feelings towards vaccines as they were growing up also happened to attest that they prefer to ask family members, instead of healthcare professionals, for medical advice. These results suggest that a number of participants place a high priority on the family unit. Although more completed surveys are necessary to adequately power the results of this study, the preliminary findings point to opportunity for education and interventions geared towards the family unit in order to reach individual patients in this particular community.

Conclusion: Preliminary results suggest that familial influence impacts vaccination practices of respondents as they transition from childhood into adulthood. Interestingly, it appears that this predominantly Hispanic community primarily looks to family members instead of healthcare professionals when it comes to making vaccine decisions. Additionally, the participants who grew up with family members who had negative feelings towards vaccines appear to be the ones who depend on the family unit when making immunization decisions. These preliminary results highlight an opportunity for healthcare providers to focus on educating families to improve patient immunization outcomes.

Poster Title: Assessing the current status of pharmacy involvement in transition of care programs within hospital institutions in the Rio Grande Valley

Primary Author: Sharon Thomas, The University of Texas at Austin College of Pharmacy, Texas; **Email:** sharonthomas@utexas.edu

Additional Author (s):
Daniela Bazan
Bianca Cruz
Kariana Pena

Purpose: Transitions of care (TOC) refers to the movement of patients between health care practitioners, settings, and home as their care needs change. These transitions increase the risk for medication-related adverse events and higher hospital readmission rates. Consequently, hospital institutions have begun to instate pharmacist-led TOC programs that can include medication reconciliations, medication counseling, and follow-up phone calls. Pharmacists utilize a patient-centered approach to review therapy and assess medication issues. This study evaluates the current status of pharmacist involvement in TOC programs in the Rio Grande Valley (RGV) in order to establish a need to develop pharmacist-led TOC programs within hospitals.

Methods: With approval from the institutional review board, the Director of Pharmacy from nine acute care institutions in the RGV were contacted via telephone and informed about the study by members of the research team. The phone numbers were obtained through the acute care facility websites, which is public information. If the subjects agreed to participate, their email addresses were obtained, and a link to the survey was sent electronically. The online Qualtrics survey included the recruitment email and consent. Survey data was collected through Qualtrics at the end of the survey period. The survey provided both quantitative and qualitative data.

Results: There was a 78 percent response rate of participants in the study (n equals 7). All of the institutions surveyed had some form of a TOC model; however, the pharmacy department plays an active role in less than 50 percent of these institutions. Of the institutions where the

pharmacy department does not have an active role in the TOC program, only 25 percent had future plans to incorporate the pharmacy department. Some of the common perceived advantages of pharmacy involvement include decreased rates of readmission due to medication errors or incomplete pharmacotherapy information and decreased risk of confusion and error regarding home medications during both admission and discharge. The perceived barriers to incorporating the pharmacy department in transitions of care include lack of resources, time, and administrative support.

Conclusion: Statistics show that there is a disparity of education, income, and health in the RGV when compared to the state and national averages. By attaining a definitive look at whether institutions in the RGV have recognized the benefits of having a TOC program, are in the progress of developing one, and the challenges they encountered or anticipate facing, this study lays the groundwork for enhancing existing TOC programs and developing new pharmacist-led TOC programs in the future.

Poster Title: Medication non-adherence predictors in bipolar patients

Primary Author: Hangyul Lee, The University of Texas at Austin College of Pharmacy, Texas;
Email: hanlee127@gmail.com

Additional Author (s):
Stephen Saklad

Purpose: Medication non-adherence is a barrier to successful treatment in bipolar patients that can be modifiable through use of behavioral training and motivational techniques. Before implementing an intervention, it is important to identify factors that contribute to non-adherence. Pharmacists, having frequent contact with patients, can take an active role in addressing non-adherence through focused medication counseling. This project was initiated to determine factors related to medication non-adherence that will assist pharmacists when counseling patients with bipolar disorder.

Methods: A Medline search (1946 to present) was performed using the exploded MeSH terms "bipolar disorder" and "medication adherence." Results were initially limited to randomized controlled trials. Due to a low yield, this restriction was removed to allow a broader selection of studies including observational and cross-sectional. Additional articles were identified after review of the reference lists of selected studies. Reported data for demographic and clinical predictors and patient perceptions were considered for this report. Subjects of the selected studies had been diagnosed with either bipolar disorder type I or II and treated with various medications.

Results: A total of 14 studies were identified that met the selection criteria. Patient-related factors associated with non-adherence included: marital status, being a minority, presence of co-morbid substance abuse disorder, earlier onset of illness, suicide attempts, and others. Psychological factors relevant to non-adherence can be explained by patient perceptions and attitudes. Lack of insight and denial of bipolar disorder diagnosis were found to be associated with increased rates of non-adherence. Treatment-related barriers to medication adherence expressed by patients included fear of adverse effects, addiction to the medication, doubts about medication efficacy, and an overall negative attitude towards treatment. Other reasons

considered to be contributory towards non-adherence included: forgetfulness, unfavorable social environment, and inadequate understanding of bipolar disorder. Limitation to this evaluation is the variation in methodologies across the different studies. Results can be strengthened by developing a standard study design using defined measurement tools to assess non-adherence.

Conclusion: Using the results of clinical and demographic features associated with non-adherence, pharmacists can better identify bipolar patients that are likely to be non-adherent to treatment. Subsequently, they can address the individual factors that most likely contribute to non-adherence such as illness insight, denial of diagnosis, and fear of side effects during medication counseling sessions. Pharmacist interventions using motivational interviewing and educational techniques should positively impact long-term patient outcomes through relapse prevention and decreased hospitalizations of bipolar patients.

Poster Title: Identifying types of pharmacy student interventions made during an interprofessional six-week adult internal medicine rotation

Primary Author: Melanie Jabalie, The University of Texas at Austin College of Pharmacy, Texas; **Email:** mmjabalie@utexas.edu

Additional Author (s):
Celeste Vinluan
Jacquelyn Navarrete
Margie Padilla

Purpose: The practice of pharmacy is progressing and requires pharmacists who are integral members of a healthcare team and share in therapeutic decision-making. The new standards for pharmacy education require that pharmacy students are involved in direct and interprofessional team-based care in multiple practice settings, which include real-time interactions with prescribers and student prescribers. The objective of this study is to identify the type and number of interventions, clinician acceptance, clinical importance of pharmacy student interventions, and time to complete interventions that were performed during in an interprofessional internal medicine team.

Methods: From April 2014 to December 2015, fourth-year Doctor of Pharmacy (PharmD) students at University Medical Center in El Paso, Texas, recorded their interventions into a Microsoft Access ® database. The database includes five major types of interventions such as Adverse Drug Reaction (ADR), Interactions, Drug Therapy, Dosing, and Patient/Provider. These five intervention types are further subdivided into specific intervention categories. For all the interventions performed, the outcomes were recorded as physician accepted, not accepted, or continued to monitor. The students rated their interventions in categories of minor, moderate, or severe clinical importance Time per intervention was reported in categories of ≤ 15 minutes, ≤ 30 minutes, and one hour or greater. Descriptive statistics were performed on the collected data. The study was exempt by the University of Texas at El Paso Institutional Review Board.

Results: A total of 531 interventions were documented, resulting in an average of 44 interventions per student (n=12). Physicians accepted 462 of the student interventions, which provided an overall acceptance rate of 87%. The most frequent types of interventions performed by PharmD students were under the categories of Therapy Needed (29.8%), Too Low Dose/Frequency (21.1%), Too High Dose/Frequency (8.3%), Therapeutic Level Monitoring (6.8%), and IV to PO Conversion (4.9%). A majority of interventions was of moderate clinical importance (56.1%) and took approximately 15 minutes to complete (92.5%).

Conclusion: The results of this study illustrate the potential value of these interventions in improving patient care and support the idea that PharmD students offer appropriate recommendations to help improve patient care. This study shows that PharmD students are beneficial additions to interprofessional teams. The high physician acceptance rate may indicate that interprofessional team-based care may promote greater acceptance of PharmD student interventions, which could lead to better interprofessional collaboration. PharmD students under supervision of clinical faculty on an interprofessional internal medicine team are valuable collaborators and contributors in decreasing the number of drug-related problems that can negatively impact patient care..

Poster Title: Moxifloxacin as definitive therapy for Streptococcus anginosus infections

Primary Author: Cameron Pickard, The University of Texas at Austin College of Pharmacy, Texas; **Email:** cpickard@utexas.edu

Additional Author (s):
Sarah Hallowell
Elizabeth Hand
Andre Arizpe

Purpose: Streptococcus anginosus, a subset of viridans streptococci with variable hemolysis patterns, makes up part of the normal oral and gastrointestinal flora in humans. S. anginosus infections can range from relatively simple to life-threatening, and the incidence has been increasing at our institution. Beta-lactams have been the traditional treatment of choice for these infections, while fluoroquinolone use has historically been discouraged. The purpose of this study was to evaluate the use of moxifloxacin, a newer fluoroquinolone with more potent gram-positive activity and convenient once daily oral dosing, for the treatment of S. anginosus infections.

Methods: An institutional review board approved retrospective chart review of all patients with at least one positive culture for S.anginosus between January 1, 2011 and December 31, 2015 was conducted. Patients were identified through a query of the microbiology laboratory database and then subsequently cross-referenced with pharmacy billing records to identify patients with a charge for moxifloxacin. Patients who were pregnant, incarcerated, did not receive systemic antimicrobials, or who died within 48 hours of admission were excluded. Demographic data including age, gender, weight, comorbidities, race, and ethnicity code were collected. All culture data available during the index admission were collected in addition to any systemic antimicrobials received. Antibiotic susceptibilities and moxifloxacin minimum inhibitory concentrations (MICs) were recorded when available. Outcomes included hospital length of stay (LOS), re-isolation of S. anginosus within 30 days of treatment, 30-day hospital readmission for an infectious complication, and in-hospital mortality.

Results: We identified 29 patients with a S. anginosus infection treated with moxifloxacin. The mean patient age was 51 years (range: 26-77), with the majority being female (16/29, 55%). Patients were predominantly white (93%) and Hispanic (48%). Hypertension and diabetes mellitus represented the most common patient comorbidities. Four patients were admitted directly to the intensive care unit. The most common isolation sites included oral/maxillofacial (n=9) and wound/abscess (n=8). Ten patients had positive bone cultures or osteomyelitis. Other sites included respiratory (n=5), intra-abdominal (n=6), blood (n=3), and central nervous system (n=1). Most infections were polymicrobial (19/29, 66%), with anaerobes as the most common co-pathogen. Moxifloxacin MIC testing was performed for three patients and ranged from 0.25-0.5 mcg/mL. Vancomycin and piperacillin/tazobactam were the most common empiric therapies. The majority of patients were discharged with moxifloxacin as their definitive outpatient antibiotic for the treatment of S. anginosus (21/29, 72%). The average duration of total antibiotic therapy was 34 days (range: 3-65) and average duration of moxifloxacin therapy was 24 days (range: 1-63). The average hospital LOS was 10 days (range: 3-35). Only one patient required readmission within 30 days due to suspected infectious complications, no patients had S. anginosus re-isolated, and no patients died.

Conclusion: S.anginosus infections have increased at our institution over the last decade. Moxifloxacin is an attractive therapy option for treating these infections due to its once daily dosing, high bioavailability, and potent in vitro activity against this pathogen. Minimal clinical data, however, exists to support its use. In this preliminary evaluation of the utility of moxifloxacin for S. anginosus infections, only one patient was readmitted within 30 days, and no patients had documentation of intolerance to the medication. This initial investigation supports the further evaluation of moxifloxacin for treatment of S. anginosus infections, particularly in comparison to traditional beta-lactam therapy.

Poster Title: Barriers and biases towards the human papilloma virus (HPV) vaccination in the Hispanic culture

Primary Author: Ginger Garza, The University of Texas at Austin College of Pharmacy, Texas; **Email:** ginger.rae.garza@utexas.edu

Additional Author (s):
Lydia Aguilera
Daniela Bazan
Kassandra De La Garza

Purpose: The Centers for Disease Control reports fifty-six percent of girls and thirty-four percent of boys have been immunized with the first dose of the Human Papilloma Virus (HPV) vaccine in Texas. The Healthy People 2020 Initiative has set a goal of eighty percent vaccination rates by the year 2020. This research project aims to gauge bias and ascertain barriers relating to the HPV vaccine in a largely Hispanic population to determine how to best address them in an educational intervention to encourage vaccination and cancer prevention in a vulnerable population.

Methods: Recruitment occurred at Dr. Juan Aguilera's Pediatric Clinic in Pharr, TX. The research team surveyed 134 patients in the triage station of the clinic. Patients were asked if they were interested in completing a survey regarding the HPV vaccine for research purposes. Of the 134 patients, 112 met the inclusion criteria (18 years or older and accompanying a minor younger than 18 years of age). The survey was provided on an iPad via Qualtrics in both English and Spanish. It contained an initial consent followed by the fifteen-question survey. Baseline characteristics collected included zip code, sex, ethnicity, age, relationship to minor, and level of education of the guardian. Upon completion, each participant was provided an educational pamphlet containing basic information pertaining to the vaccine and the importance of immunization.

Results: A total of 112 participants completed the survey. The baseline characteristics gathered match statistics reported for the South Texas region along the United States- Mexico border. Among the participants, 99 percent were confident that vaccinations against Meningitis, Polio, Tetanus, Pneumonia, Cancer, Hepatitis A and B and Mumps were extremely important or very important. Additionally, 74 percent felt that vaccines would not have long-term effects. Participants stated they heard of the vaccine from a medical provider (54 percent), on television (41 percent), or had never heard of the vaccine (14 percent). Of the participants surveyed, 34 percent had a child who had been vaccinated with the HPV vaccine, 42 percent had a child who had not been vaccinated, and 25 percent were not sure. Of those with a child who had not been vaccinated, 65 percent were interested in vaccinating their child after the survey. Twenty- five percent of participants stated they were not interested in having their child vaccinated with the HPV vaccine in the future. Of this population, the barriers and biases identified include: vaccine would encourage child to have sex, harmful side effects, belief that the vaccine is only for females, or thought their child was too young.

Conclusion: The HPV vaccine can prevent and decrease mortality rate from cancer. Therefore, this is a valuable and worthy endeavor that deserves increased research efforts. From this sample, we determined that 50% of people had heard of the vaccine on television or from a healthcare provider. These two sources have been identified as preferred channels for education to increase vaccination coverage along the US- Mexico border. Funding to promote the vaccine through television ad campaigns and an in office video presentation are potential beneficial approaches to increase education and awareness for HPV vaccination.

Submission Type: Evaluative Study

Session-Board Number: 2-375

Poster Title: National epidemiology of cystic fibrosis hospitalizations in the United States between 2001 and 2010

Primary Author: Sarah Hallowell, The University of Texas at Austin College of Pharmacy, Texas; **Email:** sp_hallowell@utexas.edu

Additional Author (s):
Cameron Pickard
Andre Arizpe
Kelly Reveles

Purpose: While cystic fibrosis (CF) has traditionally been considered a high mortality childhood disease, recent advancements in its treatment have extended the median age of survival to over 40 years in developed countries. Rates of CF and associated patient characteristics, however, have not been described in a national cohort of patients in recent years. The purpose of this study was to investigate the national epidemiology of CF hospitalizations longitudinally and overall in the United States over a 10-year period, including patient age, prevalence, regional and seasonal variation, and hospital length of stay (LOS).

Methods: We performed a retrospective analysis of the United States National Hospital Discharge Survey (NHDS), which provides a nationally representative sample of inpatient discharges from non-federal, acute care hospitals. Individuals with a principal or secondary ICD-9-CM diagnosis code for CF (277.XX) between 2001 to 2010 were included. Frequency weights were used to derive national case estimates. Prevalence per 10,000 discharges and median hospital LOS were presented overall and annually. Additionally, we evaluated prevalence by geographic region and season. Geographic regions were defined per the United States Census Bureau. Seasons were defined as follows: winter (Dec-Feb), spring (Mar-May), summer (Jun-Aug), and fall (Sep-Nov).

Results: The data represent 246,181 hospitalizations for CF during the study period. The majority of patients visited a nonprofit hospital (80%), had admissions classified as urgent (43%) or emergent (31%), and were admitted via referral (57%). The median (IQR) patient age was 17 (10-25) years. Overall, an increase in median age was observed from 16 years in 2001 to 22

years in 2010. The prevalence of CF hospitalizations was highest in 2004 (7.9/10,000 discharges) and lowest in 2009 (4.8/10,000 discharges). Prevalence generally decreased during the study period. The South and West had a much lower cumulative prevalence, 4.9/10,000 and 3.9/10,000 discharges, respectively, than the Northeast (9.5/10,000 discharges) and Midwest (8.2/10,000 discharges). The cumulative 10-year prevalence remained generally consistent over the four seasons, with the highest prevalence in winter (6.5/10,000 discharges) and the lowest prevalence in fall (6.3/10,000 discharges). The overall median hospital length of stay (IQR) was 7 days (3-13).

Conclusion: Overall, there was an increase in the median annual age of patients hospitalized for CF and a decrease in yearly prevalence. Analysis of prevalence by geographic region revealed considerable variation. No prominent seasonal variations were identified. With revolutionary treatments approved after 2010, a follow-up epidemiological investigation of the subsequent 10 years may reveal drastic advances in CF patient outcomes.

Submission Type: Descriptive Report

Session-Board Number: 2-376

Poster Title: Exploring Healthy Food Choices in a US-Mexico Border

Primary Author: Lauren Ramos, The University of Texas at Austin- College of Pharmacy, Texas;
Email: lmramos23@gmail.com

Additional Author (s):
Jeri Sias
Eufemia Garcia

Purpose: Healthier weights can be achieved by changing dietary habits. Calorie counting is one way to identify areas of improvement. A community agency serving a rural US- Mexico border offered nutrition education classes and recipes modification tips to participating community members. The agency worked in collaboration with a regional pharmacy school to explore healthy food choices. The purpose of this project was to work with the community agency to evaluate caloric breakdown of traditional Mexican recipes developed from the nutrition classes and to provide healthier versions.

Methods: A pharmacy student calculated content of traditional Mexican dishes prepared during the class and provided healthier caloric alternatives for those same Mexican dishes. The student used an online nutritional calculator for each recipe item based on measurements provided by the participants. Description of the highlights and challenges in this process were documented to provide feedback for the agency to improve their nutrition education services. To help the agency learn about the surrounding community, several pharmacy students administered a questionnaire on an electronic tablet (English/Spanish) between the Summer of 2015 and Fall of 2016. Data was gathered in a non-randomized convenience sample. The survey was based on questions developed from published literature and was focused on personal and family health and willingness to change eating habits

Results: The pharmacy student calculated caloric content when evaluating 10 traditional and 10 improved recipes for traditional Mexican dishes. Some individuals created new recipes that they thought were healthier alternatives, but in fact provided little improvement. The pharmacy student observed that individuals did not always decrease carbohydrates or fats for better nutritional balance. Challenges occurred when finding caloric content for certain food

items of traditional Mexican dishes. Further, the pharmacy student observed that selection of healthier recipe alternatives may have been limited by lack of understanding of portion control, not including affordable fresh vegetables, and using higher-sodium canned items. Sixty-five (n 65) surveys were collected (80 percent female, 38 percent Spanish speakers) in this rural community. Fifty-seven percent of participants try to eat healthy foods every day, 43 percent want to lose weight, and 39 percent were ready to improve their family's health but indicated that it was difficult to change. Thirty-one percent of participants wanted to improve their family's health by eating more fruits and vegetables and 18 percent wanted to eat smaller portions.

Conclusion: This project revealed gaps in patient's knowledge about healthy alternatives in traditional Mexican recipes. The application of nutritional knowledge does not always get translated into practice when community members are preparing meals for themselves or their family. Through the survey, participants were open to learning health tips and understood that dietary changes needed to be made. This information can be used to incorporate new methods of educating the community in portion control and healthier alternatives to Mexican dishes. Pharmacists' increasing involvement in health and wellness requires additional investments to be made to learn about the community in which they serve.

Poster Title: Utility and correlation of lactic acid (LA) and procalcitonin (PCT) for diagnosis and prognosis of patients presenting with sepsis or septic shock.

Primary Author: Pari Wafayee, University of Houston, Texas; **Email:** pari.wafayee@gmail.com

Additional Author (s):
Ronda Akins
Melisande Hinds
Caitlin Le

Purpose: Sepsis is characterized by devastating consequences as the syndrome progresses into septic-shock and multi-organ failure. Mortality rates are estimated to be over 10% for sepsis and 40% in septic shock. Currently, lactic acid is the established biomarker assessed for diagnosis of sepsis, as well as an indicator of prognosis and perfusion. Whereas procalcitonin has been used to evaluate the likelihood of having a systemic bacterial infection antibiotic treatment requirement, and duration. This study was designed to evaluate and compare the utility of lactic acid and procalcitonin as biomarkers in the diagnosis of septic shock and the prediction of hospital mortality.

Methods: This was a retrospective study of patients admitted to Methodist Charlton Medical Center for the treatment of sepsis or septic shock . The study was conducted as part of a routine quality review process. Patients admitted with sepsis or septic shock from September 1, 2015 to July 31, 2016 were reviewed to determine whether lactic acid and procalcitonin levels were reported. Patients were included if they were 18 years of age or older, diagnosed with septic shock with a lactic acid greater than or equal to 2 mg/dL, and had a procalcitonin level drawn within the first 24 hours of sepsis diagnosis. Subjects meeting inclusion criteria were then further reviewed for serial lactic acid and procalcitonin values, demographic data, microbiological/serological data (positive vs negative cultures and bacterial vs fungal/viral) and additional laboratory values. The primary outcome was to assess whether any correlation between lactic acid and procalcitonin values exists in the diagnosis of septic shock, including if LA or PCT was more closely associated with other infectious indicators (WBC, etc). The secondary outcome was to assess the correlation of lactic acid and procalcitonin values to hospital mortality and positive cultures growing bacterial or fungal organisms.

Results: The preliminary cohort screened a total of 80 patients for the inclusion criteria. Forty-five patients met the inclusion criteria. The majority of the patient population was African-American (26 patients), followed by Caucasian (17 patients) and Hispanic (1 patient). There was no correlation between LA and PCT for the initial value and diagnostic utility of sepsis (p = 0.97). PCT ranged from < 0.05 to 29.42 mg/L despite elevated LA levels greater than 2 mg/dL (range 2.1-18.4 mg/dL). Fifty-three percent of patients had a positive bacterial culture with PCT being significantly correlated (p=0.05) but there was no correlation noted for having a positive culture (p=0.44). LA had no correlations with bacterial infections (p=0.94) or positive cultures (p=0.84). When analyzing other infection indicators, there was a weak correlation for PCT to WBCs and neutrophils and LA to WBCs and interestingly it was noted that increases in LA was associated with a decreases in neutrophils. Although the mortality rate was high at 71%, there was no association for PCT (p=0.43) or LA (p=0.8) for all-cause mortality.

Conclusion: Among our preliminary cohort, there was no correlation identified for procalcitonin and lactic acid values being utilized as biomarkers for the initial diagnosis or as prognostic indicators. Regardless of LA or PCT levels, mortality was high. While PCT was associated with positive bacterial cultures, there was no overall association in predicting an infectious process. Similarly, LA was not associated with any infectious processes despite down trending in serial levels. Future evaluations need to include patients with LA levels less than 2mg/dL and serial levels to better understand potential utility.

Poster Title: Assessing the compliance to a glycemic control protocol in the intensive care unit setting

Primary Author: Susan Lowrie, University of Houston College of Pharmacy, Texas; **Email:** smlowrie@uh.edu

Additional Author (s):
Boxin Xu

Purpose: Hyperglycemia is common in the intensive care unit (ICU), and if not properly controlled, has been associated with worse clinical outcomes. A glycemic control protocol was implemented in the ICU of a community hospital for hyperglycemia management. In order to assess if further education was needed for nurses, an investigation was conducted to identify how many nurses were following the protocol when treating patients.

Methods: This study was carried out by two pharmacy interns (fourth year pharmacy students) and one pharmacist with advanced training (residency). Patients in the study were identified using the Cerner electronic medical record. Inclusion criteria were patients in the ICU during April 2016. Patients were excluded if they had DKA or did not have a blood glucose level greater than 150. The insulin drip infusion protocol was based on the Atlanta Protocol and the sliding scales used were developed by a group of pharmacists and physicians within the hospital system. Data was collected from the electronic medical record to see if each step of the glycemic control protocol was followed. A "yes" was recorded if all steps of the protocol were followed. A "no" was recorded if at least one step of the protocol was not followed and the steps not followed were also recorded. The "yes" and "no" responses were counted and a percentage was calculated for each response over the total number of patients. For the patients who had a "no" recorded, the specific steps not followed were also totaled.

Results: A total of 44 patients were examined to see if they were treated according to protocol. 6 of the patients (13.6 percent) received treatment that followed protocol, while 38 patients (86.4 percent) did not. Of these 38 treatments that did not follow protocol, 22 patients had no A1C taken and 16 patients received the wrong insulin dose.

Conclusion: Although protocols have been put in place to help improve patient outcomes in the ICU, this study showed that not all nurses treated patients according to the established protocols. Further education would be beneficial to ensure all patients with hyperglycemia in the ICU are treated in a uniform manner.

Submission Type: Evaluative Study

Session-Board Number: 2-379

Poster Title: Metoprolol in atrial flutter or atrial fibrillation with rapid ventricular response in the emergency center

Primary Author: Holly Ryan, University of Houston College of Pharmacy, Texas; **Email:** hsryan@uh.edu

Additional Author (s):
Jennifer Gass
Heather Hartman
Brittany Pelsue

Purpose: Management of acute atrial fibrillation (AF) or atrial flutter (AFL) with rapid ventricular response (RVR) requires prompt ventricular rate or rhythm control. Atrial fibrillation is the most common arrhythmia presenting to the emergency center (EC); however, both AF and AFL are managed similarly. Current guidelines recommend intravenous (IV) administration of a beta-blocker or nondihydropyridine calcium channel antagonist to slow ventricular heart rate. Metoprolol is a commonly used IV rate-controlling agent in the EC. This study aims to evaluate the efficacy and safety of IV metoprolol in the EC for controlling rapid ventricular rate in patients presenting with AF or AFL.

Methods: The institutional review board approved this single center, retrospective observational study. Adult patients aged 18 years and older who presented to the EC at Memorial Hermann – Texas Medical Center with a primary or secondary diagnosis of AF or AFL with RVR, defined as a heart rate greater than 110 beats per minute (bpm), and who received IV metoprolol as a first-line agent were included in the study. Pregnant women, prisoners, and patients transferred from another institution were excluded. A total of 297 patients were considered for inclusion from February 6, 2015 to May 31, 2016. Thirty patients met the inclusion criteria. The primary outcome measure was a target heart rate of less than 110 bpm within 30 minutes from administration of the first dose of IV metoprolol. Secondary endpoints included adverse effects such as bradycardia (heart rate < 60 bpm) and hypotension (systolic blood pressure < 90 mmHg), the need for a second rate or rhythm-control agent, maintenance of rate control, time to initiation of oral rate-control medications, length of stay (LOS) in the EC, and final disposition. Data was analyzed using SPSS version 22 for Windows.

Results: Twenty-eight patients seen in the EC were diagnosed with primary or secondary AF with RVR; 2 were diagnosed with AFL with RVR. Males and females were evenly distributed. The average age was 67.7 plus or minus 13.9 years. Metoprolol achieved a target heart rate less than 110 bpm within 30 minutes in 17 (56.7 percent) patients. Twelve (40 percent) patients required a second rate or rhythm control agent including either IV diltiazem or amiodarone. One (3.3 percent) patient required electrical cardioversion in the EC. Nine (30 percent) patients received oral medications, with an average time to administration of 60.08 plus or minus 42.12 minutes from initial bolus dose. Seven (23.3 percent) patients were discharged from the EC and 23 (76.7 percent) were admitted to the hospital, including the intensive care unit [7(23.3 percent)], intermediate care unit [9 (30 percent)], or general floor [7(23.3 percent)]. The average LOS in the EC was 6.2 plus or minus 2.7 hours. Bradycardia and hypotension occurred in 2 (6.7 percent) and 4 (13.3 percent) patients, respectively.

Conclusion: The use of metoprolol as an initial agent in the management of AF or AFL to control rapid ventricular heart rate was successful in 17 (56.7 percent) patients in the EC compared with 12 (40 percent) patients who required a second rate-control agent. Metoprolol was shown to be effective in achieving rapid rate control without notable adverse effects in 24 (80 percent) patients. Expanding the present study to include a greater number of patients over a longer period of time is required to further study the safety and efficacy of metoprolol in patients presenting with AF or AFL with RVR.

Poster Title: Diltiazem in atrial fibrillation and/or atrial flutter with rapid ventricular response in the emergency center

Primary Author: Lydia Solis, University of Houston College of Pharmacy, Texas; **Email:** ldmatar@uh.edu

Additional Author (s):
Jennifer Gass
Heather Hartman
Brittany Pelsue

Purpose: Atrial fibrillation (AF) and atrial flutter (AFL) are the most common arrhythmias that present to emergency centers (EC). One of the therapeutic goals in management of these arrhythmias presenting with rapid ventricular response (RVR) is ventricular rate control. According to current guidelines, intravenous (IV) administration of a beta blocker or non-dihydropyridine calcium channel antagonist is recommended to slow the ventricular heart rate. Diltiazem or metoprolol are commonly used in emergency centers for this purpose, with no conclusive evidential difference between them. This study aims to evaluate the use and describe the safety and efficacy of diltiazem in the emergency center.

Methods: This single center, retrospective cohort, observational study has been approved by the Institutional Review Board. Data was collected through review of electronic medical records. Patients 18 years or older who received IV diltiazem in the EC for ventricular rate control in AF and/or AFL were evaluated. Approximately 100 patients admitted to the EC at Memorial Hermann – Texas Medical Center from June 1, 2015 through June 15, 2016 were considered for inclusion. Exclusion criteria include pregnant patients, prisoners, and patients transferred from another institution. The primary endpoint is to determine percentage of patients who achieved rate control, defined by a heart rate less than 110 beats per minute within 30 minutes of administration of first dose of diltiazem. Secondary endpoints include adverse effects following administration of diltiazem, need for second rate control medication, need for cardioversion, maintenance of rate control from EC admission to hospital admission or discharge from EC, time to initiation of oral rate control medications, length of stay in EC, and patient disposition. Possible adverse effects included bradycardia, defined as heart rate less

than 60 beats per minute and hypotension, defined as systolic blood pressure less than 90 mmHg. Data was analyzed using SPSS Version 22.0 for Windows.

Results: There were 30 patients who met inclusion criteria, with an average age of 60.7 (26-89) years and average weight of 88.2 (46.8-136.8) kilograms. Males comprised 16 (53.3 percent) patients and 14 (46.7 percent) were females, while 17 (56.7 percent) presented with new onset AF and/or AFL. Length of stay in the EC was an average of 7.3 (2.5-20.1) hours. For the primary endpoint, diltiazem achieved rate control within 30 minutes of the first dose in 19 (63 percent) patients. A total of 5 (16.7 percent) patients experienced adverse effects after diltiazem administration, 3 (10 percent) with hypotension and 2 (6.7 percent) with bradycardia. The need for administration of another rate control medication occurred in 11 (36.7 percent) patients. Maintenance of rate control was achieved for an average of 27 (plus or minus 29) percent of the total time patients were in the EC. Additionally, cardioversion was not required for any patients. The average time to initiation of oral rate control medication in these patients was 149 (20-365) minutes. After treatment, 5 (16.7 percent) patients were discharged from the EC, 10 (33.3 percent) were admitted to general floors, 13 (43.3) to intermediate care floors, and 2 (6.7%) to critical care units.

Conclusion: Diltiazem was effective in achieving rate control of AF or AFL with RVR in 63 percent of patients. Adverse effects occurred in less than twenty percent of patients who received diltiazem. Diltiazem appears to be safe and effective in the management of AF or AFL with RVR in the EC. Expansion of this study to include more patients over a longer period of time would provide more insight into these results.

Poster Title: Evaluation of sodium bicarbonate and mannitol combination infusion for the management of acute kidney injury

Primary Author: Caroline Root, University of Houston College of Pharmacy, Texas; **Email:** carolineroot13@gmail.com

Additional Author (s):
Teresa Allison
Jennifer Gass

Purpose: Sodium bicarbonate is commonly administered for the prevention of acute kidney injury (AKI), as studies show protective effects in preventing and reducing the severity of AKI through attenuation of oxidative stress on renal cells. While literature supporting mannitol administration as a renally protective agent is available, there is a broad array of mixed evidence. There are no current studies on the concomitant administration of sodium bicarbonate and mannitol in AKI. The purpose of this study is to evaluate the efficacy, safety and outcomes of sodium bicarbonate and mannitol combination infusion for the management of acute kidney injury.

Methods: This institutional review board approved single-center, retrospective, observational, descriptive study evaluated the combination infusion of 75 mEq sodium bicarbonate and 12.5 g mannitol in one liter of half- normal saline at varying rates for a minimum of 24 hours in patients with renal dysfunction admitted to Memorial Hermann – Texas Medical Center from July 2013 – February 2016. Patients were included if they were 18 years or older and received the combination product. Exclusion criteria included pregnant patients, patients with chronic renal failure requiring renal replacement therapy before admission, and the need for dialysis this admission prior to initiation of the combination infusion. The primary endpoint was to describe the change in serum creatinine in patients receiving sodium bicarbonate and mannitol combination infusion. The secondary endpoint was to describe the relationship of urine output (UO) to the volume of combination infusion therapy received.

Results: Thirty patients were included. Twenty patients reported a past medical history (PMH) of chronic kidney disease (66.7 percent), 2 were stage 2 (10 percent), 13 were stage 3 (65 percent), and 5 were stage 4 (25 percent) not requiring dialysis. Additional PMH included hypertension in 29 patients (96.7 percent), diabetes in 18 (60 percent), heart failure in 15 (50 percent), cardiac arrest in 10 (33.3 percent), and previous AKI in 8 (26.7 percent). The mean [standard deviation (SD)] serum creatinine in patients who received the combination infusion for the 24 hours prior to initiation was 2.36 mg/dL (1.08) and 1.94 mg/dL (1.01) after discontinuation of the combination infusion. The average duration of infusion of the combination infusion was 2.7 (1.7) days. Twenty-two (73.3 percent) patients received concomitant n-acetylcysteine, and 23 received IV contrast (76.7 percent). Average UO in the 24 hours prior to infusion was 597 mL/patient/day and patients averaged 1581 mL/patient over the two days after infusion initiation. The combination infusion dose averaged 1002 mL over the two days after infusion initiation. The most frequent adverse event reported was hypotension, occurring in 7 (23.3 percent) patients, followed by anemia and bradycardia each in 4 (13.3 percent) patients.

Conclusion: Recipients of this therapy were patients at high risk of AKI, as past medical history of chronic kidney disease, hypertension, diabetes, heart failure, and cardiac arrest were common. Improvement was seen in serum creatinine after use of the combination product and may support the utilization of this therapy. Urine output was very closely reflective of the volume of fluid received with the combination product. Therefore, whether this infusion therapy is preferential to other forms of fluid as treatment for acute kidney injury is unclear. However, the improvement in serum creatinine observed in this study warrants further large scale investigation.

Poster Title: Evaluation of blood pressure management and outcomes in ischemic stroke patients with or without a prior history of hypertension

Primary Author: Krutina Garcia, University of Houston College of Pharmacy, Texas; **Email:** kapatel3@uh.edu

Additional Author (s):
Chelsea Wong
Jennifer Gass
Teresa Allison

Purpose: Approximately one-half of patients presenting with an acute ischemic stroke (AIS) take scheduled antihypertensive medications. Currently, the risk-benefit ratio for lowering or raising the blood pressure during the initial 24 hours of acute ischemic stroke is unknown. The reinitiation of antihypertensive agents and the timing of such should be individualized to the patient based on current hemodynamic status, stroke subtype, and patient specific comorbidities. The purpose of this study is to evaluate blood pressure management and outcomes in ischemic stroke patients with a prior history of hypertension compared to patients without a history of hypertension.

Methods: This single center, retrospective, cohort study evaluated patients admitted with an ischemic stroke from July 2015 to July 2016 to a comprehensive stroke center. Patients 18 years or older with a primary diagnosis of acute ischemic stroke were included in the analysis. Pregnant women or those who received blood pressure management greater than 24 hours at an outside hospital were excluded. Data collection included patient demographics, National Institute of Health Stroke Scale (NIHSS), Glasgow Coma Scale (GCS), stroke types, blood pressure goals, blood pressure values and antihypertensive regimens during the hospitalization, length of stay (LOS), disposition, modified rankin scale (mRS) and outcomes.

Results: A total of 32 patients were included; 9 did not have a history of hypertension and 23 had a history of hypertension. The median [interquartile range (IQR)] NIHSS was 3 (1-9) in those with history of hypertension and 3 (1-8) in those without history of hypertension. Patients with history of hypertension had a mean [standard deviation (SD)] age of 70.4 (16.2) years compared

to 59.7 (16.6) years in those without history of hypertension. Mean (SD) admission systolic blood pressure (SBP) was 158.7 (33.1) mmHg in the history of hypertension group compared to 137.9 (22.8) mmHg for those without history of hypertension. Patients with a history of hypertension received an average of 2.9 antihypertensive medications, while those without hypertension received an average of 1 antihypertensive medication. The mean (SD) discharge SBP for those with history of hypertension was 126.0 (21.4) mmHg compared to 116.8 (15.7) mmHg in patients without history of hypertension. Median (IQR) LOS was 5.2 (4.1-6.3) days in patients with a history of hypertension and 4.7 (3.3-6.9) days in patients without history of hypertension. The median (IQR) discharge mRS was 3 (1-4) in patients with history of hypertension compared to 2 (0.5-3.5) in those without history of hypertension.

Conclusion: We observed that patients with a history of hypertension presented with higher blood pressures at admission and required more antihypertensive agents to manage blood pressure during the hospital stay. Additionally, the LOS was longer in patients with a history of hypertension compared to those without a history. Currently, the sample size is too small to make any conclusions. The plan is to expand this to a larger sample size and conduct a more robust analysis of the blood pressure values and antihypertensive medication regimens.

Poster Title: Evaluation of single administration of intravenous acetaminophen for pain control in postpartum patients

Primary Author: Thuy-Duong Lam, University of Houston College of Pharmacy, Texas; **Email:** vivianlam06@gmail.com

Additional Author (s):
Hina Momin
Amy Schilling

Purpose: Intravenous (IV) acetaminophen (APAP) has been used as an adjunct analgesic agent for pain management in perioperative surgeries. Oral and IV acetaminophen have similar effects but differ slightly in the onset of action. However, the cost of IV APAP is significantly higher than oral formulation, 42 dollars per a 1-gram vial versus 2.61 dollars for 100 tablets of 500-milligram APAP. Therefore, in September 2015, Memorial Hermann The Woodlands Hospital implemented an automatic one-dose stop of IV APAP. The aim of this study is to evaluate the effectiveness of one dose of IV APAP for pain control in postpartum patients.

Methods: This study was a retrospective case-control study that evaluated the use of single dose of IV APAP for pain management in postpartum patients. The study included all patients who received at least one dose of IV APAP for pain control during a 72-hour postpartum period from August 15 – September 14, 2015 as the pre-protocol group and November 1-30, 2015 as the post-protocol group. Patients under 18 years of age were excluded from the study. The electronic medical record was utilized to provide a comprehensive profile of patients, pain medication consumptions, naloxone administered, and other safety concerns. The data was then analyzed to evaluate the primary and secondary outcomes. The primary outcomes were the effectiveness of the one dose IV APAP protocol, which was evaluated based on opioid analgesic consumption in IV morphine equivalents (ME) and changes in pain scores using average of highest pain scores. Opioid consumption and pain scores were evaluated during 0-24-hour, 24-48-hour, and 48-72-hour postpartum periods. Secondary outcomes included hospital length of stay (LOS), administration of more than 4 grams APAP in 24 hours, changes in hepatic functions (liver function tests (LFTs) greater than 3 times upper limit of normal (ULN)), and naloxone use as a reversal agent for opioid overdose.

Results: A total of 164 patients were included in the study (pre-protocol, n equals 113; post-protocol, n equals 51); baseline characteristics were similar in both groups. Most patients underwent cesarean section (pre-protocol, 98.2 percent; post-protocol, 92.3 percent). Compared to the pre-protocol group, opioid consumption was 13.2 percent higher in the post-protocol group during 0-24-hour period but 10.4 percent and 9.6 percent lower during 24-48-hour and 48-72-hour periods, respectively. Pain scores were lower in the post-protocol group for all three periods (0-24-hour, 17.8 percent lower; 24-48-hour, 8.1 percent lower; 48-72-hour, 8.1 percent lower). LOS was comparable in both groups (pre-protocol, 3.2 days; post-protocol, 3.3 days). No patient in the post-protocol group exceeded 4 grams APAP in 24 hours while 13.3 percent of patients in pre-protocol group exceeded the maximum. Of the 31 patients whose LFTs were documented, no patient had LFTs greater than 3 times the ULN at admission and discharge. Lastly, total of 9 patients received naloxone (pre-protocol, n equals 7; post-protocol, n equals 2), but only one patient, in the post-protocol group, received it for respiratory depression reversal; others received it for itching.

Conclusion: A one-dose IV APAP stop protocol was found to lower pain scores and resulted in less incidents of administration of more than 4 grams of APAP in 24 hours with similar safety concern profile compared to multiple-dose IV APAP for postpartum patients. Although opioid consumption was higher during the first 24-hour period in post-protocol patients, it was lower during the second and third 24-hour periods.

Poster Title: Liposomal bupivacaine in the cardiac population

Primary Author: Stella Hwang Kim, University of Houston College of Pharmacy, Texas; **Email:** smhwang@uh.edu

Additional Author (s):
Jennifer Gass

Purpose: Recently, the use of liposomal bupivacaine has increased in the cardiac population despite the lack of evidence and approval for this use. As administration increases, it becomes important to describe this off-label utilization and identify its impact on patient safety and efficacy. The purpose of this study is to assess the utilization for indication, dosing, and impact of efficacy and safety.

Methods: This single center, retrospective descriptive cohort study approved by the institutional review board evaluates the utilization of liposomal bupivacaine in adult patients in the Heart and Vascular Institute at Memorial Hermann – Texas Medical Center from July 1, 2014 through June 30, 2016. Patients were excluded from the study if they were under the age of 18, pregnant, or had fewer than three documented pain score measurements after administration of liposomal bupivacaine. The primary objective was to determine the procedures where liposomal bupivacaine was used and the doses utilized. The secondary objectives included assessment of pre-procedural pain scores versus post-procedural pain scores.

Results: Of the 30 patients evaluated, the majority of liposomal bupivacaine use was for a thoracotomy (35 percent) and device manipulation (35 percent); the remainder of utilization varied among an assortment of procedures including transcatheter aortic valve replacement and coronary artery bypass grafting. All documented utilization was for a total of 20 mL of undiluted 1.3 percent liposomal bupivacaine. The median pain scale documented for the 24 hours prior to administration of liposomal bupivacaine was 0 (interquartile range: 0, 0). For the 24 hour period following administration the median pain score was 0 (interquartile range: 0, 3). On average three different medications were administered concurrently with liposomal bupivacaine, with the most common medications being acetaminophen (75 percent) and

acetaminophen-hydrocodone (45 percent). No significant rates of adverse effects were observed in this patient population.

Conclusion: Off-label administration of liposomal bupivacaine in the cardiac population was used status post a variety of cardiovascular procedures. The standardized dosing of liposomal bupivacaine used in these procedures was 266 mg (20 mL), and though the median pain score 24 hours post-administration elevated, noted by the interquartile range, the patients within this population still remained well managed with a minimal amount of opioid usage. The clinical significance of these effects must be determined in a larger long-term prospective trial.

Poster Title: Evaluation of blood pressure management in ischemic stroke patients admitted with a blood pressure less than or greater than 180mmHg

Primary Author: Chelsea Wong, University of Houston College of Pharmacy, Texas; **Email:** chelseanwong@gmail.com

Additional Author (s):
Krutina Garcia
Jennifer Gass
Teresa Allison

Purpose: The majority of patients with an acute ischemic stroke (AIS) present with a systolic blood pressure (SBP) greater than 140 mmHg. Extreme low and high elevations of SBP have been associated with poor outcomes. Blood pressure management in AIS patients is a major component of inpatient treatment and may impact disposition. Current guidelines do not state a definitive blood pressure goal to adhere to for secondary prevention. The purpose of the study was to investigate the outcomes of ischemic stroke patients admitted with either a SBP less than 180 mmHg or a SBP greater than or equal to 180 mmHg.

Methods: This institutional review board approved retrospective, single center, cohort study evaluated blood pressure management in patients with acute ischemic stroke (AIS) from June 2015 to July 2016 at a comprehensive stroke center. Patients 18 years or older with an acute ischemic stroke were included. Pregnant patients or patients transferred from an outside hospital greater than 24 hours after the initial onset of symptoms were excluded. Data collection included patient demographics, past medical history, stroke type, daily blood pressure goals, blood pressure values, antihypertensive regimens during hospitalization, length of stay (LOS), Glasgow Coma Scale (GCS) scores, and outcomes.

Results: Thirty-two patients were included; 27 patients presented with a SBP less than 180 mmHg (less than) and 5 patients presented with a SBP greater than or equal to 180 mmHg (greater than). All patients in the greater than group had a history of hypertension. The less than group had a mean [standard deviation(SD)] age of 67.9 years (17.2) and 59 percent were female compared to a mean (SD) age of 64.4 years (14.9) and 60 percent female in the greater

than group. Median (range) admission GCS scores in the less than group was 15 (7-15) and 15 (3-15) in the greater than group. Mean (SD) admission SBP in the less than group was 143.0 (21.6) mmHg compared to 205.8 (24.5) mmHg in the greater than group. Patients in the less than group received an average of 2 medications throughout hospitalization compared to 4 in the greater than group. Seventy-five percent of the less than group required at least one medication upon discharge whereas 80 percent of the greater than group required at least 2 medications. The median [interquartile range (IQR)] LOS in the less than group was 5.6 (4.2-6.3) days compared to 5.2 (3.9-6.1) days in the greater than group.

Conclusion: We observed that patients admitted with a SBP greater than or equal to 180 mmHg required more medications throughout their stay and were also discharged on more medications compared to those with an admission SBP less than 180 mmHg. Currently, our sample size is too small to make conclusions. Plans are underway to expand this project to a larger sample size and a more robust analysis of blood pressure values and antihypertensive medications used.

Poster Title: Evaluation of pain management regimens in post-operative spinal surgery patients

Primary Author: Stacy Poindexter, University of Houston College of Pharmacy, Texas; **Email:** stacy.poindexter@memorialhermann.org

Additional Author (s):
Tiby Joseph
Jennifer Gass
Teresa Allison

Purpose: According to the American Pain Society Guidelines on the Management of Postoperative Pain Control, a reported eighty percent of all surgical patients will experience pain post-operation, with less than half having sufficient pain control. Pain management and associated adverse events are ongoing concerns for clinicians. Pain is best addressed from a multi-modal approach, which can be individualized based upon the procedure. This study aimed to evaluate pain management regimens as well as serious adverse events occurring in patients who underwent spine surgery.

Methods: This Institutional Review Board approved, single center, retrospective observational study evaluated patients admitted July 1, 2014 to June 20, 2016. Patients were greater than or equal to 18 years, underwent spine surgery, and required pain management. Pregnant patients were excluded. The primary outcome was assessed using patient reported pain scale scores, review of pain medications received, and incidence of adverse events post-operatively. Excess sedation was defined as a Richmond Agitation and Sedation Scale (RASS) score of minus 5 (unarousable), indicating no response to physical or verbal stimulation, over two consecutive checks. Uncontrolled pain was defined as a pain score of greater than or equal to 6 over two consecutive checks. Hypotension was defined as systolic blood pressure less than 90 mmHg or a decrease by 40 mmHg from the previous two readings. Data collection included: patient demographics, past medical history, surgery information (type, indication, length of surgery), post-operative care unit (PACU) length of stay (LOS), all pain and sedation medications the patient received from admission to 48 hours post surgery, adverse events, hospital LOS, and disposition.

Results: A total of 30 patients were included: The mean [standard deviation (SD)] age was 59.2 (13.3) years and 20 (66.7 percent) patients were male. Twenty-one patients (70 percent) were white/Caucasian. The most common surgery location was cervical (70 percent), and the most common indication was stenosis (60 percent). Twenty-three percent of patients received posterior laminectomy, which was the most common procedure. Seventeen significant adverse events occurred; 13 (43.3 percent) had uncontrolled pain, 2 (6.7 percent) experienced excess sedation, and 2 (6.7 percent) experienced hypotension. Additionally, fourteen patients (46.7 percent) experience nausea and vomiting requiring an anti-emetic post-operatively. No patient experienced respiratory depression or cardiac arrest. The overall median [interquartile range (IQR)] pain score was 3 (0-6). Of the 294 pain scores recorded, 37 percent were 0, 17 percent were 1 to 3, 28 percent were 4 to 6, and 18 percent were 7 to 10. In patients experiencing uncontrolled pain, on average, 1 episode occurred. Patients received a median (IQR) of 4 (2-4) pain medications post-operatively, with the majority receiving opioids, primarily hydromorphone and the combination product acetaminophen-hydrocodone. Mean (SD) hospital LOS was 1.2 (0.5) days. All patients were discharged home alive.

Conclusion: Post-operatively, 43.3 percent of our spinal surgery patients experienced a significant adverse event including excess sedation, hypotension, uncontrolled pain. Additionally, 46.7 percent experienced nausea and vomiting. Currently, our sample size is too small to draw any conclusions. We plan to expand this project to a larger sample size and conduct a more robust analysis of adverse events.

Poster Title: Prevalence of medication orders recommended for central line administration in hospitalized patients at Houston Methodist Hospital

Primary Author: David Pham, University of Houston College of Pharmacy, Texas; **Email:** dpham23@uh.edu

Additional Author (s):
Emmanuel Njigha
Lydia Solis
David Putney

Purpose: The placement of central lines is common for medication administration. However, the presence of a central line is associated with several complications. Evaluating medication orders that recommend central line administration can provide insight into the usage and risks of these agents at an institution. This study was conducted to identify the prevalence and describe the usage of medication orders that are recommended for administration through a central line at Houston Methodist Hospital.

Methods: This is a single center, retrospective cohort, observational study. Data was collected through a review of electronic medical records. Patients who received intravenous medications at Houston Methodist Hospital in the Texas Medical Center from July 1, 2016 through August 31, 2016 were analyzed. Recommendations for central line administration was defined using a comprehensive database review from Trissel's Handbook of Injectable Drugs. Medications were determined to be recommended for central line administration if their properties included a mean pH of less than 5 or greater than 9, osmolarity greater than 600 milliosmoles per liter and/or vesicant characteristics. Medications that differed in pH and osmolarity based on strength or diluent were not included in the comprehensive list. The primary outcome was to determine the proportion of central line recommended medications administered to hospitalized patients. Secondary outcomes included proportion of central line recommended medications given based on medication class, floor setting, and the property designating central line administration.

Results: There were a total of 190,459 intravenous medication orders that qualified during the specified time range. Of these orders, 62,057 (32.6 percent) met central line administration requirements defined in this study. The majority of these orders consisted of 27,101 (43.7 percent) electrolytes, 16,157 (26 percent) antiemetics, and 7,800 (12.6 percent) antimicrobials. The most common electrolyte was potassium chloride, equaling 16,506 (26.6 percent) orders, while the most common antiemetic and antimicrobial were ondansetron and vancomycin, equaling 15,991 (25.8 percent) and 5,108 (8.2 percent) orders, respectively. Additionally, out of 18,270 intravenous medication orders in the ICU, 6,708 (36.7 percent) of these medications qualified for central line administration. The majority of orders recommending central line administration qualified based on pH, with 33,175 (53.5 percent) having a pH less than 5 and 539 (0.9 percent) having a pH greater than 9.

Conclusion: About one-third of intravenous medications ordered during the time frame of this study were classified as central line recommended per the requirements defined in this study. Almost half of these medications were electrolytes. Out of the intravenous medications administered in the ICU, about one third of medications recommended central line administration as well. Results of this study may yield positive implications for practice in health-systems. Monitoring of medications that recommend central line administration may help to decrease the need for this type of line access in hospitalized patients.

Poster Title: Validation of ICD-9-CM/ICD-10-CM codes for automated electronic scoring of APACHE II, APACHE III, and SAPS II

Primary Author: Eric Kao, University of Houston College of Pharmacy, Texas; **Email:** eric.zhisong.kao@gmail.com

Additional Author (s):
Brian Gulbis

Purpose: Retrospective cohort studies involving intensive care unit (ICU) patients frequently describe acuity of patient illness with severity classification scores. Most risk scores use a combination of physiologic variables and comorbidities to calculate the score. While physiologic variables can often be extracted from electronic medical records (EMR), identifying comorbidities has traditionally relied on manual review of clinical documentation. This process is time-consuming and tedious with larger sample sizes, thus an automated electronic scoring tool using diagnostic coding would facilitate the process. Our study objective is to validate the use of diagnosis codes in the calculation of severity scores.

Methods: Patients admitted to an ICU between 07/01/14 and 06/30/16 were screened for the study. Patients were excluded if they were pregnant, a prisoner, or were missing data necessary to calculate a risk score. Sixty patients were then randomly selected for inclusion. Physiological and comorbidity data was extracted and manually collected for all patients in this IRB-approved, retrospective, observational study. Three severity scores were calculated: the Acute Physiology and Chronic Health Evaluation (APACHE) II, the APACHE III, and the Simplified Acute Physiology Score II (SAPS II). Each score was calculated using eight different comorbidity definitions utilizing International Statistical Classification of Diseases and Related Health Problems (ICD) codes, which were evaluated for accuracy and reliability against manual review of clinical documentation. Comorbidity sets used included a set generated by the authors through validated literature and manual collection, Agency for Healthcare Research and Quality (AHRQ), Elixhauser Comorbidity Index, and Quan's comorbidity set. Each data set included a version with and without the use of Diagnosis-Related Group (DRG) codes to exclude comorbidities related to the admitting diagnosis. The primary outcome was to determine the difference in score between electronic and manual methods amongst data sets. Secondary

outcomes include difference in predicted mortality and proportion with different comorbidities from the manual set. Comparison of severity scores was performed using paired t-test and Wilcoxon signed rank test.

Results: There was no difference in APACHE II and SAPS II severity scores for each of the eight comorbidity sets when compared with the manual set. A statistically significant difference was found in the APACHE III score for all eight comorbidity sets compared with the manual set (p-value equals 0.02 for each set). In all cases with a difference, the score using diagnostic coding was higher than the score for the manual set. Among patients with a different score from manual, the median (interquartile range [IQR]) difference for all sets was 5 (2-5) for APACHE II, 11 (7-13.5) for APACHE III, and 9 (9-9.5) for SAPS II. Predicted hospital mortality calculated using the SAPS II regression model equation was not significantly different for each set compared with manual. The proportion of patients with different comorbidities identified from manual was highest using APACHE II criteria (28.3-31.7 percent among the eight comorbidity sets), followed by APACHE III (16.7 percent differed from manual for all sets), and SAPS II (5 percent differed for all sets). There was no intra-set difference in comorbidities identified using APACHE III or SAPS II criteria.

Conclusion: These results show that diagnostic coding can reliably be used to identify patient comorbidities for the calculation of severity classification scores. Despite some variation in identification of comorbidities, there was no difference in APACHE II and SAPS II scores. Although a significant difference in APACHE III score was found, this difference was driven by comorbidity variation in a small number of patients and may not be clinically significant. The use of an electronic scoring tool based on physiologic and diagnostic data extracted from the EMR can be an efficient way to calculate severity classification scores in larger retrospective studies.

Poster Title: Effect of body mass index (BMI) on norepinephrine dosing requirements in patients with septic shock

Primary Author: Caitlin Le, University of Houston College of Pharmacy, Texas; **Email:** caitlinle64@yahoo.com

Additional Author (s):
Pari Wafayee
Ronda Akins
Melisande Hinds

Purpose: According to the Surviving Sepsis guidelines, norepinephrine (NE) is the recommended first line option for patients in septic shock requiring vasopressors for hemodynamic support. However, guidelines do not provide recommendations on whether NE dosing should be weight or non-weight-based. Recent literature suggests obese patients require less NE than non-obese patients, thus dosing should be non-weight-based. However, the study population did not encompass extreme ranges of BMI. Our facility utilizes weight-based dosing of NE with observational success. Therefore, the purpose of this study is to evaluate the outcomes of NE dosing between non-obese and obese patients with septic shock.

Methods: This was a retrospective study of patients from Methodist Charlton Medical Center, a community hospital, who were admitted with septic shock requiring NE for hemodynamic support. The study was conducted as part of a routine quality review process. Patients who were prescribed NE from September, 1 2015 to July 31, 2016 were reviewed for dosing indications. Patients were included if they were 18 years of age or older, diagnosed with septic shock with a lactic acid greater than two mmol/L, and survived at least 24 hours after sepsis diagnosis. Patients were then divided into two groups, obese (body mass index greater than or equal to 30 kg/m2) and non-obese group (body mass index less than 30 kg/m2). The following data was collected on all included patients: demographic data, pertinent laboratory values, and medication data (specifically maximum dose of NE, addition of vasopressin and/or hydrocortisone, and volume of fluids). The primary outcome was to compare between groups the maximum dosing requirements of NE during the first 24 hours of the infusion. The secondary outcomes were the requirement for the addition of vasopressin and/or

hydrocortisone, initial fluid resuscitation volume administered within the first six hours of sepsis diagnosis, and hospital mortality.

Results: The preliminary cohort consisted of 21 obese and 24 non-obese patients. There was no difference between the two groups in regards to age, gender, and race. There was a statistical difference in total body weight of 102.4 +/- 19.3 kg in the obese group and 68.3 +/- 17.6 kg in the non-obese group (p < 0.01). The maximum NE dose was 64.3 +/- 45.8 mcg/minute in the obese group and 32.5 +/- 25.5 mcg/minute in the non-obese group, (p=0.025). The initial fluid resuscitation volume administered within 6 hours was 12.7+/- 20.5 mL/kg and 29.0 +/- 25.3 mL/kg (p=0.005). The total fluid resuscitation volume at 24 hours was 20.0 +/- 23.5 mL/kg and 46.7 +/- 35.0 mL/kg (p=0.005), for obese and non-obese, respectively. Despite this difference in fluid resuscitation, no difference in mortality was correlated to fluids within 6 hours (p = 0.16) or over the first 24 hours (p = 0.25). There was no difference in the requirement for the addition of vasopressin or hydrocortisone. However, those patients that did require the addition of either agent had significantly higher hospital mortality (p < 0.05).

Conclusion: Among our preliminary cohort, obese patients with septic shock required higher maximum norepinephrine doses during first 24-hours versus non-obese patients to maintain mean arterial pressure above 65 mmHg. This data was not consistent with previously published literature. Our patients had more variation in weight, were an older population, and majority African-American. However, no difference was noted in mortality regardless of NE dose. The Surviving Sepsis guidelines does not specify NE dosing recommendations, more data is required to identify a clear consensus for broader populations and reduction of morality. Further data will continue to be gathered and analyzed at this institution.

Poster Title: Descriptive analysis of patients in a Medicare advantage plan approved for anti-diabetic patient assistance programs (PAPs)

Primary Author: Minh Hong, University of Houston College of Pharmacy, Texas; **Email:** mahong@uh.edu

Additional Author (s):
Xin Wang
Esteban Gallardo
Omar Serna
Susan Abughosh

Purpose: Diabetes treatment can include regimens that consist of two or more medications. Generic medications are available, but some options that patients benefit from are brand name, which can be expensive. Most manufacturers have patient assistance programs, which would provide their brand name medications at no cost if patients meet eligibility requirements. Evaluating the characteristics of patients accepted into these programs could provide managed care organizations valuable information regarding attributes of patients likely to be accepted, and disparities in program acceptance requiring further evaluation. This can help determine more patients that may qualify, and in turn improve patient outcomes.

Methods: A cross-sectional study was conducted among patients accepted into the various anti-diabetic patient assistance programs. The patient population was located in Houston, TX, where data was compiled using Cigna Healthspring's LivingWell clinic database. Patients were included if they were enrolled with the health plan from January 1, 2015 to December 31, 2015, and were accepted into any anti-diabetic patient assistance program. Patients were excluded if they discontinued enrollment in the health plan during the period of interest. Patient characteristics including age, gender, race, low income subsidy (LIS) status, medication class, and comorbidities were examined. Group differences were evaluated using a chi square test.

Results: In total, 175 patients with a mean age of 70 were accepted into anti-diabetic patient assistance programs. Within these 175 patients, 45.71 percent of them were male and no significant difference was documented with gender. Statistically significant differences were observed with race, where there were significantly more whites than other races (n equals 126, 72 percent, p less than 0.0001). With regards to low income subsidy status, there was a significantly lower proportion of patients with LIS (n equals 32, 18.29 percent, p less than 0.0001). Additionally, the majority of patients (n equals 119, 68 percent) were approved for the insulin class compared to the other classes of anti-diabetic medications (p less than 0.0001), and had 3 comorbidities (diabetes, hypertension and hyperlipidemia) compared to having one or two of these aforementioned comorbidities (n equals 151, 87.28 percent, p less than 0.0001).

Conclusion: Observed differences in LIS status and comorbidities can potentially be explained by the increased financial burden among patients who do not qualify for LIS and who have more comorbidities as they may be using a larger number of medications. The documented racial differences need further investigation in future research to ensure all racial groups have access to PAPs.

Poster Title: Improvement in hemoglobin A1c among patients approved for an anti-diabetic patient assistance program in a Medicare advantage plan

Primary Author: Brian Loe, University of Houston College of Pharmacy, Texas; **Email:** btloe@uh.edu

Additional Author (s):
Esteban Gallardo
Omar Serna
Xin Wang
Susan Abughosh

Purpose: Diabetes is one of the leading causes of morbidity and mortality in the United States today. Patients' diabetes can often be controlled through a clinically prescribed regimen of medications. One barrier that commonly hinders patient's adherence to anti-diabetic medications is the cost of the medication. For this reason, drug manufacturers provide assistance to patients that meet certain criteria. This assistance provides the medication to the patient free of charge. The objective of this study was to evaluate clinical benefits gained by the patients who received patient assistance programs.

Methods: A retrospective study was conducted using de-identified data provided from Cigna-Healthspring's Living Well Clinic. Patients included were accepted into anti-diabetic patient assistance programs between January 1, 2015 and December 31, 2015 and had A1c values from before and after their acceptance. A paired t-test was conducted to evaluate the difference between pre and post A1c values. Additionally, pre and post A1c values were categorized as achieving target vs. not, using the HEDIS measure target of an A1c below 9. McNemar chi square tests were used to determine if there was a significant difference in target achievement before and after using the assistance program. All statistical analyses were performed using SAS version 9.3 (SAS Institute, Cary, NC) statistical package at a priori significance level of 0.05.

Results: A total of 52 patients with records of both pre and post A1c values were included in the cohort, 34 of them were female and 18 of them were male. The mean value of pre-A1c was 0.6769 higher than the post-A1c value in patients who received free medication through

patient assistance programs, the difference was statistically significant (p=0.0057). Also, a statistical significant difference was found when categorizing pre and post A1c values into achieving target vs not by using HEDIS measure (p=0.0126).

Conclusion: Findings indicate a significant improvement in glycemic control for the patients after qualifying for the patient assistance program which can lead to better health outcomes in this patient population. Future research with a comparative group is warranted.

Poster Title: Impact of a Pharmacist-Driven Antimicrobial Stewardship Program on Hospital Outcomes

Primary Author: Monica Garza, University of Texas at Austin, Texas; **Email:** magarzak@utexas.edu

Additional Author (s):
Ron Ozuna
Gavino Garza

Purpose: Antimicrobial stewardship programs (ASP) promote appropriate use of antimicrobial agents to reduce microbial resistance while providing optimal patient-focused clinical care. The potential for spread of resistant organisms means that the misuse of antibiotics can adversely impact the health of patients who are not even exposed to them. With the escalating rate of antimicrobial resistance in hospitals across the United States, it is imperative to promote proper antibiotic use to ensure the continued efficacy of antimicrobial agents available. The implementation of an ASP in a physician-owned hospital is investigated to quantify the effects of the ASP on overall hospital outcomes.

Methods: An ASP committee that included representation from clinical pharmacists, infectious disease (ID) specialists, physicians, informatics personnel, hospital epidemiologists, microbiology personnel, and nursing was created in a community hospital in Edinburg, Texas. This ASP pharmacy-driven committee has been implemented for a total of 15 months and holds monthly meetings in order to discuss new issues concerning antimicrobial agents or updates in infectious disease treatment guidelines in order to find solutions to any issue that may arise. The ASP has also been able to regulate the use of antibiotics by enforcing formulary restrictions to ID specialists, encouraging pharmacy pharmacokinetic consultations, and implementing new protocols when prescribing antibiotic agents for patients. Monitoring of the antibiotic cost, medication use analysis, and the hospital's antibiogram was initiated to assess the benefits of the ASP on hospital outcomes.

Results: The data analyzed demonstrated the hospital's total antibiotic cost decreased by 13% and the total cost per adjusted patient day decreased by 14% compared to the previous year. The total days of therapy (DOT) per adjusted patient days from January to August 2016 was 19% based on the drug classes most commonly used in this hospital. The total yearly antibiotic use for cephalosporins, penicillins, fluoroquinolones, and carbapenems was 28%, 24%, 13%, and 10%, respectively. In addition, the hospital's 2016 antibiogram demonstrated a 42% reduction in the number of isolates with an increased resistance and a 400% increase in bacterial coverage compared to the hospital's 2015 antibiogram.

Conclusion: This ASP is unique in that is it a pharmacy-driven committee that incorporated a multidisciplinary team in order to establish better use of antimicrobial agents. It is also one of the largest and one of few ASPs initiated in the lower Rio Grande Valley. This study demonstrated a reduction of antibiotic cost and reduction in antimicrobial resistance, which had a positive impact on hospital outcomes. This ASP model is effective in optimizing the care of patients who are treated for infections.

Poster Title: Analysis of the appropriate prophylactic use of filgrastim in an ambulatory oncology setting

Primary Author: Nicole Dominguez, University of Texas at Austin, Texas; **Email:** ndominguez@utexas.edu

Additional Author (s):
Monique Aldaz

Purpose: Filgrastim is a granulocyte colony-stimulating factor that encourages the production of neutrophils. It is primarily used to prevent significant myelosuppression and reduce the incidence of febrile neutropenia. The National Comprehensive Cancer Network (NCCN) currently recommends colony-stimulating factors when the risk of febrile neutropenia is greater than 20 percent. The primary objective of this evaluation was to determine if the prophylactic use of filgrastim was being utilized appropriately in patients receiving antineoplastic therapy in an ambulatory oncology setting.

Methods: The institutional review board determined this was a performance improvement project and that it did not require their approval. Medication order information was compiled for patients who received at least one dose of filgrastim from January 2015 to December 2015. Information obtained for all individuals included chemotherapy regimen, goal of therapy, sex, and weight. Additional information was obtained for individuals who were receiving regimens associated with an intermediate to low risk of febrile neutropenia. This included age, height, creatinine, bilirubin, and surgical/wound history. Using risk factors for febrile neutropenia identified in the NCCN guidelines and literature, the use of filgrastim was classified as either appropriate or not appropriate.

Results: Data was collected from 20 individuals and a total of 110 filgrastim orders. Forty-four percent of patients received antineoplastic treatment regimens with the intention of cure, with the rest being given for palliative care. The majority of treatment regimens prescribed were associated with a low risk of febrile neutropenia, followed by intermediate and high-risk regimens, respectively. Overall, 39 percent of prophylactic filgrastim orders were determined to be inappropriate. The average number of febrile neutropenia risk factors found in patients on

intermediate and low risk regimens was 1.8, with the most common being a prior history of chemotherapy, hemoglobin below 12, and age greater than 65.

Conclusion: A notable number of filgrastim prescriptions were determined to be inappropriate. Our immediate goal is to use this information to aid in the development of a hospital-wide protocol that guides the prescribing practices of filgrastim in patients that are myelosuppressed. We aim to reduce the inappropriate use of filgrastim in order to decrease costs and associated side effects of non-indicated treatment.

Poster Title: Utilizing candida score to identify patients at increased risk for candidiasis - a retrospective cohort study

Primary Author: Jose Hidalgo, University of Texas at Austin, Texas; **Email:** tony.hidalgo@utexas.edu

Additional Author (s):
Rick Soto-Ruiz
Celeste Vinluan

Purpose: Candida species have been identified as the fourth most common cause of nosocomial bloodstream infections in the country. Mortality rates associated with invasive candidiasis are estimated to be over 40%; the highest pathogen-derived mortality in hospitals. The ability to distinguish clinically relevant invasive candidiasis from colonization can lead to earlier treatment and reduced mortality. The purpose of this retrospective cohort study is to assess the potential risk factors for invasive candidiasis by calculating a Candida Score.

Methods: The study population consists of all non-neutropenic patients admitted to the intensive care unit with positive candida in the blood or urine at University Medical Center in El Paso, Texas. A review of the study population was performed to calculate each patient's Candida Score and ascertain risk factors for invasive candidiasis. Based on clinical data, calculation of the Candida Score was performed at the time of admission, then at each time point the patient presented with a new risk factor. The following information was collected from patients' charts in order to calculate the Candida Score and provide patient demographics: age, gender, surgical date, surgical procedure, positive cultures (from any site), medication history, progress notes (to assess criteria for sepsis and use of total parenteral nutrition), length of stay, and hospital outcomes (discharge or death). Chi-square tests were used to compare categorical risk factor variables between patients with candidemia, based on hospital outcome. Candida scores were calculated for each patient, and comparisons done for previously stated risk factors. Logistic regression was used to assess the association of covariates to death. The primary regression model will assess the relevance of known candidemia risk factors, previously identified in the literature, to Hospital Outcome (1=death, 0=discharge).

Results: A total of 83 patients were included in this study to assess mortality stratified by Candida Score. The frequency of death is increased as the Candida Score increases. A Candida Score of 3 resulted in 33.3% (8/24) mortality; Candida Score of 4 resulted in 15.8% (3/19) mortality; and Candida Score of 5 resulted in 100% (4/4) mortality. A maximum likelihood estimate to assess the relationship between Candida Score and mortality showed a 0.7 decrease in survivability with every unit increase in Candida Score, indicating a positive relationship between Candida Score and mortality (p 0.0042). Analysis of the relationship between Candida Score and mortality using patient age, gender, length of stay, and Candida Score using linear regression revealed that only patient age and Candida Score were significant predictors of death (p 0.0275 and 0.0037, respectively). Additionally, an analysis was performed to examine the relationship between the number of days until treatment occurred and its effect on mortality in those with a Candida Score greater than or equal to 3. A delayed time to treatment was not significantly related to mortality (p 0.5526).

Conclusion: This retrospective cohort study was performed to assess potential risk factors resulting in invasive candidiasis by using a Candida Score that would be predictive of mortality risk. Our study determined that a Candida Score greater than or equal to 3 was associated with increased risk of mortality. The use of a bedside tool such as the Candida Score can be used to identify patients at increased risk of invasive candidiasis resulting in mortality in an acute hospital setting.

Poster Title: Association of ceftaroline with mortality and re-hospitalization among patients with pneumonia admitted to the United States veterans health care system

Primary Author: Marilyn Mootz, University of Texas at Austin College of Pharmacy, Texas; **Email:** marilyn.mootz@utexas.edu

Additional Author (s):
Rachel Britt
Allison Mootz
Kirk Evoy
Christopher Frei

Purpose: Pneumonia is the leading cause of death due to infectious disease and the eighth leading cause of death overall in the United States. Underlying patient comorbidities and advanced age complicate treatment, leading to increased morbidity and mortality. Evidence exists to support specific older drugs for treatment, yet there is not ample evidence on new agents, particularly ceftaroline. Ceftaroline demonstrates activity against common pneumonia pathogens; however, there is not much data supporting its utility in pneumonia. This study describes mortality and hospital readmission for patients with pneumonia who received ceftaroline as first--line therapy.

Methods: This was a retrospective, cohort, descriptive study of adults (age 18+ years), admitted to hospitals in the United States Veterans Affairs (VA) Health Care System, with pneumonia, between 10/1/10 -and 9/30/14, and who received ceftaroline as first-line therapy within 14 days of hospital admission. Descriptive statistics (means, medians, counts, and percentages) were used to characterize the experience of VA patients treated for pneumonia with first-line ceftaroline therapy.

Results: A total of 48 patients were included. Ceftaroline patients were primarily white (75%), with a median (interquartile range [IQR]) Charlson comorbidity score of 6 (3-10) and were more likely to be diagnosed with COPD (56%), dyslipidemia (69%), and hypertension (75%). Average patient age was 65 (59-73) years. For patients treated with ceftaroline, median time from hospital admission to study drug initiation was 1 (0-2) days and median hospital length of stay

was 8 (3-18) days. Crude mortality rates for ceftaroline were: 30-day (4%), 60-day (13%), and 90-day (15%). Hospital readmission rates were: 30--day (23%), 60--day (27%), and 90--day (27%).

Conclusion: This study provides real-world effectiveness data for first-line ceftaroline in pneumonia among elderly, predominantly white male patients with multiple underlying comorbidities. Prospective investigations in larger, more generalized cohorts are needed to confirm or refute these findings.

Poster Title: Abuse and misuse of pregabalin and gabapentin: a systematic review

Primary Author: Amanda Kitten, University of Texas at Austin College of Pharmacy, Texas;
Email: akitten191@gmail.com

Additional Author (s):
Kirk Evoy
Megan Morrison
Sarah Hallowell
Stephen Saklad

Purpose: Gabapentinoid (pregabalin and gabapentin) abuse is increasingly being reported. This study was conducted to assess the extent of gabapentinoid abuse, characteristics of typical abusers, patterns of abuse, and potential harms in order to bring this trend to providers' attention.

Methods: A systematic review of MEDLINE, Cochrane Library, ClinicalTrials.gov and FDA data, indexed through 7/28/2016, utilizing the following searches: pregabalin OR gabapentin OR gabapentinoid AND one of the following: abuse, misuse, overdose, or substance-related disorders[MESH], was conducted according to PRISMA guidelines. Additional studies were identified through review of references. All English-language epidemiologic studies, clinical studies, and case reports/series of gabapentinoid abuse/misuse/overdose (defined by ACTTION classification) were included. Animal studies were excluded. Two authors reached consensus regarding study inclusion after full-text review. The body of literature was assessed for bias qualitatively.

Results: Fifty-nine studies were included in this systematic review (24 epidemiologic, 3 clinical abuse liability, and 32 case reports/series), indicating increasing numbers of patients are self-administering, both orally and by alternate routes, higher-than-recommended doses to achieve euphoric highs. In the general population, a 1.6% prevalence of gabapentinoid abuse was observed, whereas prevalence ranged from 3-68% among opioid abusers. An international adverse event database identified 11,940 reports of gabapentinoid abuse from 2004-2015, with >75% reported since 2012. Risk factors include a history of substance abuse, particularly

opioids, and psychiatric comorbidities. While effects of excessively high doses are generally non-lethal, gabapentinoids are increasingly being identified in post-mortem toxicology analyses.

Conclusion: Possible sources of bias include: heterogeneous study designs; risk of bias in studies due to small size, retrospective nature, and single-country-origin; and assumption of class effect among gabapentinoids.

Evidence suggests gabapentinoids possess potential for abuse, particularly in individuals with a history of opioid abuse, and reports of such abuse are increasingly being documented. Prescribers should be aware of high-risk populations and monitor for signs of abuse.

Poster Title: Application of an algorithm to estimate effectiveness of biologics for rheumatoid arthritis in a large insurance database

Primary Author: Ryan Popp, University of Texas at Austin College of Pharmacy, Texas; **Email:** ryanpopp@utexas.edu

Additional Author (s):
Matthew Davis
Karen Rascati

Purpose: Claims data collected by third-party payers contain information on medications, diagnoses, and procedure codes, but generally lack information on clinical outcomes for complicated disease states such as rheumatoid arthritis. However, a validated, claims-based algorithm for estimating effectiveness of biologic agents in treating RA has recently been developed. This algorithm has been applied to various databases in order to compare the effectiveness of biologics in treating RA. The objective of our study was to implement the claims-based algorithm in a large insurance database to estimate the effectiveness of biologics in treating RA.

Methods: The cohort included patients with rheumatoid arthritis who were enrolled in a Commercial (non-exchange) or a Medicare Advantage Prescription Drug plan in the Humana database and who initiated biologic treatment between June 2007 and December 2009. Patients were required to be continuously enrolled 6 months before through 12 months after the first claim for the biologic (the index date). The four biologics examined in this study included abatacept, infliximab, adalimumab, and etanercept. Sample sizes for certolizumab, golimumab, and rituximab were too small to be included. Patients were categorized as effectively treated by the claims-based algorithm if they met all of the following 6 criteria in the 12-month post-index period: (1) a medication possession ratio greater than or equal to 80 percent for subcutaneous biologics, or at least as many infusions as specified in U.S. labeling for intravenous biologics; (2) no increase in biologic dose; (3) no switch in biologics; (4) no new non-biologic disease-modifying antirheumatic drug; (5) no new or increased oral glucocorticoid treatment; and (6) no more than 1 glucocorticoid injection. Sensitivity analysis was performed by removing the dosage increase criterion (criteria number 2), which was thought to negatively

impact the efficacy rate for infliximab due to the allowance of dosage increase in the package insert dosage criteria.

Results: A total of 1,196 individuals were included in the analysis. The index biologic was categorized as effective using the algorithm for 25.4 percent of patients overall, including 28.9 percent for subcutaneous biologics and 20.3 percent for intravenous biologics. The index biologic was categorized as effective in the first year for 30.3 percent of etanercept (102/337), 27.6 percent of adalimumab (104/377), 32.7 percent of abatacept (37/113), and 16.5 percent of infliximab (61/369) patients. Sensitivity analysis showed that there was no significant difference in the effectiveness of the biologic agents after removing the dose increase criterion.

Conclusion: Using a claims-based algorithm in a large Commercial and Medicare claims database, it was shown that infliximab was significantly less effective than either etanercept, adalimumab, or abatacept. However, when a sensitivity analysis was performed by removing the dose increase criteria, the effectiveness of the biologic agents became comparable and no significant difference was observed between infliximab and the other agents.

Poster Title: Acute brucellosis infection complicated by concurrent tuberculosis and syphilis infection treated with streamlined triple antibiotic therapy.

Primary Author: Isaac Perales, University of Texas at Austin College of Pharmacy, Texas; **Email:** isaac.perales@utexas.edu

Additional Author (s):
Bryson Duhon

Purpose: This case report details a case of acute brucellosis treated with rifampin-containing triple antibiotic therapy to also treat latent tuberculosis. A 51-year-old male presented to the emergency department with a 4-week history of fevers associated with chills, sweating, fatigue, diarrhea, mild-to-moderate abdominal pain, and 1-2 episodes of vomiting each day. The patient noted a weight loss of approximately 25 pounds and was previously treated for suspected Helicobacter pylori and Clostridium difficile infections at two different hospitals. Social history was significant for contact with pigs and cattle through his profession as a livestock inspector. He was subsequently admitted to the hospital for fever of unknown origin. During the patient's hospital stay, mild splenomegaly, elevated LFTs, and thrombocytopenia was noted, yet his comprehensive metabolic panel and complete blood count remained both within normal limits. On the 2nd day of the patient's admission, a positive fecal PCR showed presence of C. difficile, Enterotoxigenic E. coli, Shiga toxin-producing E. coli, and Norovirus. Following this test result, the patient was started on vancomycin 125 mg by mouth every 6 hours. On day 4, a positive syphilis screen was noted with an RPR titer result of 1:2, considered latent syphilis, and penicillin G benzathine 2.4 million units IM was initiated. On day 5, a positive Quantiferon Gold result was found in the presence of negative sputum AFBs, PPD, and MTB/RIF PCR which was considered a latent tuberculosis infection. On the same day, the patient's blood cultures revealed Brucella species and he was started on doxycycline 100 mg PO every 12 hours, rifampin 300 mg every 8 hours, and gentamycin 400 mg IV every 24 hours. The patient was discharged after a 10-day hospital stay with antibiotic therapy for 3 concurrent infections. The patient was continued on triple antibiotic therapy for his brucellosis which consisted of doxycycline 100 mg PO every 12 hours for 6 weeks, rifampin 300 mg every 8 hours for 6 weeks, and gentamycin 400 mg IV every 24 hours for 7 days. The latent tuberculosis treatment consisted of 4 months of rifampin 600 mg every 24 hours which included the 6-week rifampin

therapy for brucellosis. The patient's treatment of latent syphilis comprised of penicillin G benzathine 2.4 million units IM every 7 days for a total of 3 doses. The oral vancomycin regimen for suspected C. difficile infection was discontinued 5 days into therapy due to an alternative diagnosis and resolution of diarrhea. Currently, there is conflicting evidence demonstrating superior benefit of triple therapy with doxycycline, rifampin, and an aminoglycoside compared to dual therapy in the treatment of brucellosis. We describe the co-treatment of latent tuberculosis and acute brucellosis with rifampin-containing triple therapy.

Poster Title: Medication reconciliation completion rate and documentation accuracy comparison of a forensic psychiatric unit and an acute adult psychiatric admissions unit at a state hospital.

Primary Author: Pinhui Chen, University of Texas at Austin College of Pharmacy, Texas; **Email:** pinhui92@gmail.com

Additional Author (s):
Caitlin Wise
Stephen Saklad

Purpose: A 2006 Joint Commission study found that out of the 350 medication errors in their database, 63 percent were due to a breakdown of communication, half of which could have been avoided by accurate medication reconciliation. The state hospital has several types of units including acute adult admissions and adult forensic units. All of the patients suffer from serious and persistent mental illness, commonly with poor medication adherence and frequent admissions. This study compares the completion rate and documentation accuracy of medication reconciliation between these units.

Methods: This is a retrospective cohort study of all patients admitted to one forensic unit and one acute adult admission unit performed as a program review between 04-01-2016 and 08-15-2016. Data collected included patient demographic and medication information: age upon admission, gender, admission type (internal transfer or outside admission), unit, admitting physician, psychiatrist, when and if reconciliation was documented, diagnoses, medications before and upon admission. Facility policy specifies that the admitting physician or unit psychiatrist should perform the medication reconciliation within 24 hours. Pharmacists are not formally involved in the medication reconciliation process due to funding shortages. The hospital has a Medication Reconciliation Worksheet, but this is not a formal part of the medical record. Additional sources of documentation included notes and history. The medications recorded prior to admission were compared to the medications ordered by the unit physician during the first two days of the patient's admission. Immediate use or one-time use only medications were excluded, but as-needed medications from either lists were included. Unjustified discrepancies were categorized as: omitted, duplicated, contraindicated, changed,

or unclear information. The primary hypothesis is that there is no difference in 24 hour documentation rate. Secondary hypotheses are no difference due to admission type or between units in: completion rate at any time, accuracy; and no difference between clinicians performing medication reconciliation. Statistical analysis was Chi-square. P less than 0.05.

Results: A total of 53 patients were captured in the sample, acute equals 20 (40 percent), forensic equals 33 (62 percent), female equals 21 (40 percent), male equals 32 (60 percent), mean age (standard deviation) equals 41 plus-or-minus 13 years. Medication reconciliation was documented in 40 (75 percent) of the 53 patients and was documented 8.6 plus-or-minus 18 hours after admission, but 13 of the 40 (32 percent) patients had their medication reconciliation documented prior to being admitted. Medication reconciliation was documented within 24 hours in 35 (66 percent) of the records. The acute unit had 16 (80 percent) medication reconciliations completed within 24 hours compared to 19 (58 percent) on the forensic unit (P equals 0.095). Completion rate at any time were similar for acute and forensic: 16 (80 percent) versus 24 (73 percent) (P equals 0.55). Individual admitting physician completion rates within 24 hours ranged from 33 percent to 100 percent (P equals 0.59). However, internal unit transfer completions within 24 hours were: transfers between units were 30 percent versus 74 percent for new admissions (P equals 0.0075. Completions at any time were similarly fraught: 40 percent versus 84 percent (P equals 0.0038).

Conclusion: Medication reconciliation did not differ significantly between units or prescribers within 24 hours or on an absolute basis overall. However, we identified a specific problem area: transfers between units were accomplished only 30% of the time within 24 hours of the transfer. This suggests that there is an opportunity to improve the care of patients by a targeted pharmacy-based medication reconciliation program.

Poster Title: Rituximab for treatment of refractory anti-NMDA receptor encephalitis in a pediatric patient

Primary Author: Esli Tebedge, University of Texas at Austin College of Pharmacy, Texas; **Email:** esli.tebedge@utexas.edu

Additional Author (s):
Sarah Hallowell
Margaret Oates
Elizabeth Hand

Purpose: Anti-N-methyl D-aspartate receptor (anti-NMDAR) encephalitis is a devastating disease that is increasingly being identified in both children and adults with psychosis, language disturbances, behavioral changes, and motor deficits. Up to one quarter of patients with this disease will experience severe long-term neurologic sequelae or expire. Currently no consensus guidelines exist on the optimal management of patients with anti-NMDAR, though intravenous immune globulin (IVIG) is often considered first-line pharmacotherapy though up to 50% of patients may have incomplete response with this agent. Limited data exist on how patients who fail IVIG or are intolerant to this agent should be managed.

We present a case of an otherwise healthy 4 year-old child who was transferred to our facility after experiencing focal seizures and dysarthria. She exhibited loss of age-appropriate language skills to that of a 1-2 year old in addition to behavioral changes and right-sided weakness. The patient was initially placed on levetiracetam for seizure prophylaxis and underwent various diagnostic tests including electroencephalogram (EEG) monitoring and a lumbar puncture to test for cerebrospinal fluid abnormalities. During her admission she had no recurrence of seizures, but her language skills and ability to follow commands continued to decline. Similarly, her right-sided weakness was largely unchanged. The neurology team was consulted regarding the cause of the patient's symptoms and recommended administration of intravenous methylprednisolone 250 mg twice a day for five days to treat for autoimmune encephalitis. The patient had minimal resolution of symptoms with this therapy and instead experienced significant episodic irritability that was accredited to the corticosteroids. Eighteen days after her initial episode, the results of our institution's serum anti-NMDAR antibody test came back as highly elevated and the patient was subsequently diagnosed with anti-NMDAR encephalitis.

The patient was then initiated on a four-day regimen of IVIG 2 g/kg/day, which resulted in partial but still incomplete, response. She was less irritable than previously reported but her communication skills remained below baseline. After her intolerability to corticosteroid therapy and inadequate clinical response to IVIG, immunotherapy with rituximab was initiated at 375 mg/m2 per dose. The patient's speech significantly improved two days after her first infusion of rituximab. Only her fine motor movement had not yet returned to baseline.

During the patient's second follow-up visit approximately one and a half months after discharge, both her mother and the neurologist reported that she had nearly complete symptom resolution. Her speech had returned to baseline, she had no evidence of hemiparesis, and she was attending kindergarten. It was determined at that time that there was no need for continued immunosuppression.

Anti-NMDAR is an often poorly recognized cause of neurologic and psychiatric symptoms in pediatric patients that is associated with significant morbidity. Although IVIG has historically been considered first-line therapy, overall response rates remain fairly low, as was seen with our patient. Early intervention in patients with anti-NMDAR encephalitis is of paramount importance for successful outcomes and baseline recovery. Our patient experienced intolerability to corticosteroids, minimal response to IVIG, and then subsequent complete resolution of symptoms with rituximab. Further studies should be conducted to elucidate whether rituximab should be considered as part of the initial therapy of anti-NMDAR.

Poster Title: Progressive Multifocal Leukoencephalopathy and Posterior Reversible Encephalopathy Syndrome in a Bilateral Lung Transplant Recipient

Primary Author: Matthew Davis, University of Texas at Austin College of Pharmacy, Texas;
Email: mattdavis138@gmail.com

Additional Author (s):
Nicole Wilson
John Lyons
Bryson Duhon
Laurajo Ryan

Purpose: This case report describes a patient with posterior reversible encephalopathy syndrome (PRES) followed by reactivated John Cunningham Virus (JCV) manifesting as progressive multifocal leukoencephalopathy (PML) during immunosuppressive therapy for a bilateral lung transplant. A 61-year-old woman was hospitalized four months post-transplant for progressively worsening headache, altered mental status, aphasia, seizure activity, lower left extremity monoplegia, and lower left extremity paresthesia. A brain MRI at admission revealed findings suggestive of laminar necrosis in the right parietal lobe and early Wallerian degeneration in the right corticospinal tract. An EEG provided evidence of right tempo-parietal periodic lateralized epileptiform discharges. The constellation of symptoms, MRI and EEG findings were attributed to PRES. Development of PRES was thought to be secondary to tacrolimus toxicity, so the patient's immunosuppressive therapy was switched to cyclosporine. Following initiation of cyclosporine, the patient experienced increased headache which was concerning for worsening PRES, which was confirmed by a follow-up MRI. The patient was transitioned from cyclosporine to sirolimus and mycophenolate mofetil. After attaining a therapeutic sirolimus trough, the patient was discharged to a rehabilitation center for therapy due to lower extremity weakness.
While admitted to the rehabilitation center, the patient developed fevers and mild leukocytosis. She was treated with vancomycin and piperacillin/tazobactam for potential pneumonia. After 10 days of antibiotic therapy, there was little improvement in pulmonary symptoms, so the patient was readmitted to the hospital. At admission, the chest x-ray demonstrated right upper lobe (RUL) nodular thickening with a new RUL consolidation

consistent with unresolved pneumonia. A subsequent bronchoscopy and lung tissue biopsy indicated A2 acute cellular rejection. Intravenous methylprednisolone 500 mg daily was administered for three days then tapered to 20 mg oral prednisone over the course of 12 days. A repeat MRI performed during this admission showed progressive white matter changes in multiple regions of the brain. These findings, combined with positive JCV serology in the cerebrospinal fluid from a previous admission, are pathognomonic for PML.

The patient's new diagnosis combined with concerns for acute organ rejection was discussed with the patient and family. One of the primary strategies for treating PML is to restore a patient's immune system, but the team was unable to further decrease immunosuppressive agents in this patient due to acute cellular rejection. Mirtazapine 15 mg daily was initiated in an attempt to slow disease progression and to ease her increasing anxiety following this new diagnosis. Mirtazapine was chosen due to in vitro studies showing that the JCV may infect cells using the 5HT2A receptor, which is inhibited by mirtazapine. Unfortunately, her neurologic status continued to decline, as she developed slurred speech and mild right-sided weakness. She was discharged to a skilled nursing facility with eventual plans to transition to hospice care. More study into the treatment of PML is needed, particularly in solid organ transplant patients who require immunosuppression.

Poster Title: Long-acting injectable antipsychotics: Do they prevent or delay hospital readmissions?

Primary Author: Heather Rozea, University of Texas at Austin College of Pharmacy, Texas;
Email: heather.rozea@utexas.edu

Additional Author (s):
Thomas Maestri
Lisa Mican
Jamie Barner

Purpose: One of the most common reasons for rehospitalization and relapse in patients diagnosed with bipolar disorder, schizophrenia, and schizoaffective disorder is medication non-adherence. Long-acting injectable (LAI) antipsychotics were developed as a way to decrease pill burden in this patient population and to simplify medication regimens by allowing less frequent administration. The purpose of this study was to determine whether long-acting injectable antipsychotics prevent or delay hospital readmission in patients with a known history of medication non-adherence.

Methods: The institutional review board approved this retrospective, matched evaluation study. Men and women aged 18-65 who were diagnosed with bipolar disorder, schizophrenia, or schizoaffective disorder and were discharged between November 30, 2011 to November 30, 2013 from Austin State Hospital, an inpatient state hospital were included in the study. These patients had to have documented medication non-adherence, either during the current admission or previous reports, and be prescribed a first generation LAI antipsychotic (fluphenazine decanoate or haloperidol decanoate) or second generation LAI antipsychotic (paliperidone LAI or risperidone LAI) or a corresponding scheduled dose of oral "equivalent" first or second generation antipsychotic. Patients were matched based on psychiatric diagnosis, "equivalent" oral dose, number of prior admissions, and length of stay. Patients were excluded if they had a length of stay greater than one year or less than two days. The definition of oral "equivalent" doses were fluphenazine LAI dose divided by 1.25, haloperidol LAI dose divided by 10, paliperidone LAI dose divided by 20, and risperidone LAI dose divided by 10, with each calculation rounded to the closest available oral dose. The primary objective was to determine

whether LAI antipsychotic use was associated with an increased time to readmission in patients diagnosed with bipolar disorder, schizophrenia, or schizoaffective disorder with a known history of non-adherence and whether one-year readmission rates were decreased.

Results: Those who received a LAI (N=120, MeanSE: 278+/-11.5 days) had a significantly longer (Chi-square = 3.9054, df=1, p=0.0481) survival time without readmission compared to those who did not (N=120; MeanSE: 243.6+/-12.8 days). There was no statistically significant difference in the frequency of one-year readmission between those who did receive a LAI (43.1%) and those who did not (56.9%)(Chi-square= 3.3419, df=1, p=0.0675). At the p < 0.10 level, differences were significant, with higher proportion of subjects who did not receive LAI (13.8%) being readmitted. Those who received a LAI with administration frequency of a month or longer (MeanSE: 307.9+/-13.1 days) had a significantly (Chi-square=6.5180, df=1, p=0.0107) longer survival time without readmission when compared to those who did not receive a longer administration LAI (MeanSE: 245.0+/-18.5 days). No statistically significant difference was revealed in mean length of stay on readmission between those who did receive a LAI (44.3+/-47.3) and those who did not (50.1+/-75.6)(t-value=0.47, df=1, p=0.6384). There were no statistically significant differences in survival time without readmission (Chi-square=2.3543, df=1, p=0.1249) between those who received an second generation LAI (MeanSE: 268.6+/-15.9 days) and those who received a first generation LAI (MeanSE: 199+/-10.5 days).

Conclusion: This study revealed the use of LAI antipsychotics, particularly those with longer administration frequency, to have potentially promising outcomes in those patients with a history of non-adherence. Further studies should be conducted in order to confirm these results on a larger scale.

Poster Title: Benefit of liver-kidney transplant for renal graft function in a highly-sensitized patient refractory to desensitization with plasma exchange and intravenous immunoglobulin

Primary Author: Yoko Hirase, University of Texas at Austin College of Pharmacy, Texas; **Email:** hirase.yoko@gmail.com

Additional Author (s):
Rebecca Brady
John Lyons

Purpose: This case report demonstrates a highly-sensitized patient who underwent a liver-kidney transplant in conjunction with desensitization techniques with plasma exchange (PLEX) and intravenous immunoglobulin (IVIG) as methods to decrease the risk of graft rejection. The patient is a 61 year-old female with a history of end-stage liver disease (ESLD) secondary to hepatitis C virus complicated by hepatocellular carcinoma and end-stage renal disease secondary to type II diabetes mellitus who was on hemodialysis three times a week since April of 2010. She had been on the waitlist for transplant since 2011 partly due to her high calculated panel reactive antibodies (cPRA) of 100%. She was admitted to the hospital for management of her ESLD, and desensitization was initiated with twice-weekly PLEX and IVIG with follow-up HLA antibody testing in anticipation for organ availability in the near future. She remained highly sensitized with cPRA at 100% despite 8 sessions of PLEX and IVIG, in which she maintained strong HLA antibody production against HLA-A2, A26, B13, B35, and Cw6 and several moderate and weak HLA-antibodies. The antibody levels limited the likelihood of finding a suitable donor as it posed a significant risk for antibody-mediated rejection (AMR) post-transplant. Therefore, successful desensitization prior to kidney transplant relied heavily on the transplanted liver's ability to clear circulating antibodies. A suitable donor with HLA that included HLA-A2 and B35 became available on hospital day 27. The liver was transplanted first, in hopes of removing antibodies directed against the kidney graft. For induction, the patient received rabbit anti-thymocyte globulin (rATG) 75 mg (1.5 mg/kg) intra-operatively to the liver and two more doses of rATG on post-operative days (POD) 1 and 4. Donor-specific antibodies (DSA) post-liver transplant were obtained and showed the liver's success in clearing some antibodies, displayed by the removal of a majority of the moderate and weak antibodies and the decrease in HLA-A26 and B13 antibodies to moderate levels. However, antibodies directed at HLA-A2 and B35

remained strong. The following day, the kidney was transplanted, and she was initiated on maintenance immunosuppression with tacrolimus, mycophenolate mofetil (MMF), and methylprednisolone taper. Intermittent PLEX and IVIG were continued post-transplant according to DSA levels that were closely monitored after each session. However, this had minimal effects on decreasing antibody production, and strong HLA-A2 and B35 antibodies remained. Oliguria continued, indicating delayed graft function, and she required hemodialysis on POD 7. A renal biopsy was performed on POD 6 and supported AMR indicated by positive DSA, positive Cd4 staining, and apparent tubular epithelial cell necrosis accompanied by minimal peritubular capillaritis. PLEX and one dose of rituximab 700 mg (375 mg/m2) were initiated followed by PLEX and IVIG for AMR treatment. This treatment yielded hopeful outcomes due to increases in urine output, reaching to greater than 0.6 mL/kg/hr. Unfortunately, acute kidney injury secondary to septic shock complicated her treatment, requiring re-initiation of hemodialysis. This case report suggests that the transplant of a liver graft prior to a kidney graft can help with the desensitization process by removing HLA-antibodies. However, it may not eliminate all of the circulating antibodies that could target the kidney graft. For this patient, AMR prevention with PLEX and IVIG plus preceding the kidney transplant with a liver graft appeared unsuccessful. Future studies can focus on other available agents in preventing AMR when the presence of strong HLA-antibodies is known.

Poster Title: Gauging uninsured patients' access to prescription medications using coupons from drug discount programs in a primarily Hispanic population

Primary Author: Xin Ying Oh, University of Texas at Austin College of Pharmacy, Texas; **Email:** xsoh@utexas.edu

Additional Author (s):
Bianca Cruz
Lydia Aguilera

Purpose: In 2015, 28.6 million people in the United States remained uninsured while prescription sales were 419 billion dollars, an 11.7 percent increase compared to 2014. Uninsured patients utilize discount coupons, engage in medical tourism, purchase medications online, or do not fill their prescriptions when they cannot afford their medications. Financial difficulties increase medication inaccessibility and lead to poor patient health outcomes, particularly in the impoverished South Texas Region that includes a largely Hispanic population. Medication adherence is impossible without medications. The purpose of this project is to assess uninsured patients' access to prescription medications in a predominantly Hispanic region.

Methods: The institutional review board approved this research project. Pharmacist managers of retail chain and locally-owned independent pharmacies (n equals 21) were contacted at their place of business and recruited to voluntarily participate in a four question survey about drug discount programs. Subjects who chose to participate were verbally consented and assured all information would be kept strictly confidential. Pharmacists were queried regarding acceptance of prescription coupons. If they did not accept coupons, then follow-up questions sought to determine the reasons for not honoring coupons in their pharmacies. They were also asked to comment on negative and positive experiences with prescription drug coupons. The final question in the survey included a request for permission of two follow-up phone calls in English and Spanish by an unidentified researcher to any member of the pharmacy staff regarding honoring prescription coupons at that particular pharmacy for a second phase of the study.

Results: The response rate was 81 percent. Seventeen subjects consented, 2 declined, and 2 could not be reached. Forty-one percent (n equals 7) of participants stated they do accept coupons from discount drug programs versus 59 percent (n equals 10) of participants who stated they do not accept coupons from discount drug programs. Of the subjects who do accept discount drug coupons, 43 percent (n equals 3) cited overall positive experiences because they play a role in helping patients with their medication expenses. 43 percent (n equals 3) of subjects who do accept drug discount coupons also cited overall negative experiences due to cost issues, and 14 percent (n equals 1) cited positive and negative experiences. Of the subjects who do not accept discount drug coupons, 40 percent (n equals 4) had in-house programs that were preferable, 50 percent (n equals 5) had specific policies against accepting them, and 10 percent (n equals 1) reported poor reimbursements. Out of all the participants, 71 percent (n equals 12) have experienced cost issues, such as hidden transaction fees. Less than one percent (n equals 1) stated that the process is simple, while 12 percent (n equals 2) stated that the process is complicated.

Conclusion: The majority of the participants stated their pharmacy does not accept coupons from discount drug programs. Medical providers need to be made aware of the situation surrounding prescription coupons. Clearly, if they are making assumptions regarding procurement of medications via prescription discount coupons, they are in for a surprise tantamount to that of the researchers in this study. A second phase of this approved study will involve follow-up phone calls by unidentified researchers posing as patients inquiring about the acceptance of discount coupons to determine if a disparity exists for Spanish or English callers in a predominantly Hispanic population.

Poster Title: To Screen or Not to Screen? Utilization of a Scoring System for the Transition of Care Program at a Comprehensive Cancer Center.

Primary Author: Nikhil Mantravadi, University of Texas College of Pharmacy, Texas; **Email:** nikim@utexas.edu

Additional Author (s):
Man-Khoi Nguyen
Phuoc Anne Nguyen
Gilbert Castro
Frank Tverdek

Purpose: Medication reconciliation has been shown to improve patient outcomes. The Pharmacy Transitions of Care (TOC) team at the University of Texas MD Anderson Cancer Center explored methods to best maximize efficiency by optimizing a new electronic health record (EHR), the 2015 version of Epic® . The team created a TOC dashboard with a scoring system feature to prioritize admitted patients based on likelihood of medication intervention being needed. The objective was to determine the effectiveness of the dashboard scoring system to identify patients with higher need for interventions to review.

Methods: This was a retrospective review of all patients assessed by the TOC team from October 2015 to July 2016. Patients were excluded during May 2016 as the transition to Epic® took place and TOC activities were inconsistent during the month. Patients prior to May were reviewed in a sequential fashion. Outcomes from these patients were compared to those reviewed after Epic® implementation. Review in Epic® utilized a score ranking system aimed to review patients at highest risk for medication related discrepancies. The scoring system is comprised of weighted scores related to factors such as age, poly-pharmacy, high risk medication classes, and allergies. Primary outcomes assessed were types of intervention and time spent reviewing each patient. Intervention types included pharmacist actions such as adding or removing medications or updating details of the medication order. Additional outcomes included length of stay and time to medication history. Descriptive statistics were utilized to analyze factors that may indicate the effectiveness of the dashboard to screen patients with higher acuity level. Continuous variables were compared with Student's T-test,

and categorical variables have been compared by chi-square test or Fisher's exact test, as appropriate.

Results: The post-implementation group included 54 patients. The pre-implementation group included 290 patients. Mean time spent on TOC activity increased from 12 to 15.9 minutes per patient. Patients in the intervention group had a length of stay approximately 0.8 days longer. Patients in the post-implementation group were also receiving more medications with a mean of 2 more medications per patient. The mean time to medication history from admission was reduced by approximately 4.8 hours. The number of medication history actions decreased from an average of 2.2 actions to 1.3 actions.

Conclusion: The implemented scoring system appeared to be identifying more acutely ill patients, as indicated by the increased length of stay, number of medications per patient, and time to complete medication histories. The use of EPIC® also decreased response time for medication history. However, the hypothesis was rejected based on the fewer medication history actions documented in the post-implementation period in comparison with the pre-implementation group. A number of confounders may be influencing results. Further data collection is warranted before making recommendations. The future direction is to further assess the quality of the dynamic scoring system.

Poster Title: Oral chemotherapy adherence rates among patients treated with everolimus calculated using proportion of days covered (PDC)

Primary Author: Michael Kent, University of Texas College of Pharmacy, Texas; **Email:** michael.kent1287@utexas.edu

Additional Author (s):
Karthryn Broze
Neal Dave
Jim Schwarts

Purpose: Purpose: Everolimus is a common chemotherapy treatment for several different malignancies. Adherence of chemotherapy medication is paramount to treatment success. Oral chemotherapy drugs allow for more convenient administration of chemotherapy medication. However, the success of these treatments are dependent on patient compliance. Proportion of days covered (PDC) is a calculation used to measure a patient's medication adherence rate. PDC is a more accurate measurement of adherence than medication possession rate (MPR), because it prevents the over estimation of adherence caused by early refills.

Methods: Methods: This study was a retrospective chart review of patients who filled their everolimus prescriptions at a Texas Oncology pharmacy from January 1st of 2013 to December 31st of 2015. 381 patients were reviewed for this study. Patients were excluded if they only filled one prescription of everolimus. Patients were also excluded if there is a gap in fills > 30 days past the date the patient would have used the full days' supply of the most recent prescription fill, and the chart did not clearly cite noncompliance, or list an excusable reason for this gap. 94 patients were excluded from the study due to these exclusion criteria. Adherence rates were calculated using Proportion Days Covered (PDC). Days covered was determined by the date the patient picked up their prescription, and the days supply of that prescription. This was compared to the total number of days the patient should have been on therapy. If the patient refilled their prescription before the previous refill's days supplied had been completed. Then the newest refill would not be started until the previous fill's days supplied had been completed. The definition of compliance was set as a PDC greater than or equal to 90%. Patients charts were reviewed to determine the reason for noncompliance if documented.

Results: Results: The mean PDC for patients receiving everolimus was 92%. The majority of patients had a compliance rate higher than 90%. There was no reason given for the patient's noncompliance in a majority of the patient charts. The most common documented reason for noncompliance was toxicity, of which the most common toxicity was mucositis. Other toxicities included infection, rash, back pain, and anemia. Patients were often excluded from the study because of disease progression causing large gaps in therapy.

Conclusion: Conclusion: The majority of patient were highly compliant on their chemotherapy regimen. The reasons for patient noncompliance are not well documented. More information is required to determine the reasons for patient noncompliance. This is an important area for future research as oral chemotherapy regimen become more prevalent.

Poster Title: Risk of acute liver failure from bodybuilding herbal and dietary supplements.

Primary Author: Samantha Gonzales, University of the Incarnate Word, Texas; **Email:** sjgonzal@student.uiwtx.edu

Additional Author (s):
Rebecca Brady

Purpose: This case report highlights the potential risk of the unregulated market of bodybuilding herbal and dietary supplements that have been implicated in acute hepatic failure. A 34-year-old Hispanic male was transferred from an outside hospital to a transplant facility after three weeks of progressive jaundice, mid-epigastric abdominal discomfort, nausea, and mild forgetfulness. Labs upon admission included total bilirubin: 22.9 mg/dL, alkaline phosphatase: 128 U/L, AST/ALT: 4542/3742 U/L, INR: 2.1, ammonia: 57 micromol/L, lactate: 732 mmol/L, and MELD score: 29 points. The patient was diagnosed with acute liver failure with grade I hepatic encephalopathy and placed on the transplant list. While providing supportive care, the team began trying to determine the cause of the liver failure and evaluate him for liver transplant. His past medical history included treatment for bronchitis over one month prior to the start of symptoms that was treated with ciprofloxacin and methylprednisolone dose pack. No symptoms were reported after completing the treatment. He had a tattoo three months prior to admission. The patient took no routine prescription medications or over-the-counter products, including acetaminophen. He denied illicit drug use. A toxicology screen was performed which returned with negative results, including acetaminophen. This eliminated prescription medications and acetaminophen toxicity as a possible cause. He reported taking bodybuilding nutritional supplements for over a year, which included branched chain amino acids (BPI Sports Best BCAA), creatine, whey, and casein (Optimum Nutrition). The patient had currently been working to become a personal trainer and motivational coach. While the exact mechanism of hepatotoxicity is not fully known, herbal and nutritional supplements have previously been implicated in acute liver failure. The patient reported increased alcohol consumption starting three months prior that included drinking an average of 10 beers per week. No known drug allergies were reported or any other medical conditions. The patient also denied any recent travel outside of the United States. Tests were performed to assess for autoimmune and viral hepatitis and all were negative. Tests for genetic liver disease were

negative. An abdominal sonogram was performed showing a "starry sky" appearance suggesting acute hepatitis with no evidence of venous thrombosis, hepatic mass, or infiltrative process. Additionally a liver biopsy was performed showing cholestasis with minimal necrosis, nothing to suggest autoimmune hepatitis, supporting the possibility for acute liver failure due to drug induced liver injury. Supportive and pharmacologic care was provided to manage the complications of his acute liver failure. The patient's AST/ALT peaked on hospital day 2 at 4565/4573 U/L, and total bilirubin peaked on hospital day 15 at 26.4 mg/dL. With continued clinical improvement, the patient's transplant was placed on hold with the hopes that the patient's own liver would recover. He continued to show signs of hepatic improvement over the course of the hospital stay. Upon hospital discharge, his AST/ALT remained elevated but had decreased to 183/282 U/L, alkaline phosphatase was elevated at 173 U/L, total bilirubin was elevated but decreased to 3.4 mg/dL and his INR was normal. This case brings attention to the risk of acute liver failure from unregulated bodybuilding supplements in an otherwise healthy adult patient population.

Poster Title: Candida glabrata peritonitis: Questions about fluconazole dosing and duration of treatment

Primary Author: Kaitlen Shumate, University of the Incarnate Word Feik School of Pharmacy, Texas; **Email:** shumate@student.uiwtx.edu

Additional Author (s):
Kathleen Lusk

Purpose: This case highlights the uncertainty in how to appropriately treat intra-abdominal infections caused by Candida glabrata, susceptible to fluconazole, with respect to dosing and duration of treatment. Our patient was admitted to the medical intensive care unit for gastric ulcer perforation. He required intubation, and a laparotomy was performed. Shortly afterwards, he developed septic shock and required norepinephrine. He also progressed into atrial fibrillation but was cardioverted into normal sinus rhythm with amiodarone. The patient has a past medical history significant for end stage liver disease secondary to alcoholism, ascites, and hepatic encephalopathy as well as a past surgical history of transjugular intrahepatic portosystemic shunt. Baseline liver function tests for the patient include total bilirubin of 7.0 mg/dL, alkaline phosphate of 120 U/L, AST of 21 IU/L, and ALT of 10 IU/L. One week after the laparotomy, purulent discharge from the incision site on the abdomen was noted. A diagnostic paracentesis was performed to rule out peritonitis. The peritoneal fluid returned with a white blood cell count of 88, 13% segmental neutrophils, a glucose of 130 mg/dL, and a total protein of less than 3 g/dL. The culture grew Candida so the patient was empirically initiated on fluconazole 100 mg by mouth daily. Two days later, the organism further speciated as Candida glabrata. After review of the Infectious Diseases Society of America guidelines for the management of candidiasis, the patient was switched to micafungin 100 mg IV daily because echinocandins are recommended as first line therapy. The microbiology lab was called to determine if the Candida glabrata was susceptible to fluconazole in hopes that the patient would have an oral option as he was being prepared for discharge. The Candida glabrata did return as susceptible to fluconazole. After receiving 5 days of micafungin treatment, the patient was switched to fluconazole 400 mg by mouth daily based on these susceptibilities. Additional review of the Infectious Diseases Society of America guidelines found that intra-abdominal infections caused by Candida glabrata are to be treated similarly to candidemia. Candidemia

caused by Candida glabrata that is susceptible to fluconazole should be treated with high dose fluconazole daily. This recommendation was taken into consideration along with the dose response of Candida glabrata to fluconazole. Two days after fluconazole 400 mg was initiated, the dose was increased to 800 mg by mouth daily. There were concerns with using high dose fluconazole in this patient due to his medical history of end stage liver disease. The package insert cautions the use of fluconazole in patients with underlying liver dysfunction and recommends to monitor the AST levels. The patient's AST remained stable while inpatient. The recommended duration of treatment for this patient was unclear. Determining treatment duration is based on adequate source control and clinical response; however, no specific recommendation for the appropriate treatment duration is available. The internal medicine team consulted the infectious disease team who recommended a 14-day course of antifungal therapy. The patient completed the remaining 7 days of therapy on fluconazole 800 mg by mouth daily following discharge.

Poster Title: Assessing social media use by U.S. pharmacy schools

Primary Author: Stefanie Van Boskerck, University of the Incarnate Word Feik School of Pharmacy, Texas; **Email:** vanboske@student.uiwtx.edu

Additional Author (s):
Amy Diepenbrock
Bradi Frei
Cheryl Horlen

Purpose: Social media has become the latest tool for pharmacy schools to engage applicants, students, alumni, and the broader public. It is an opportunity to share information, advertisements, and news related to pharmacy issues and health matters. Universities may be aware of the capabilities of social media, but these technologies may not be used to their fullest potential. The purpose of this study is to evaluate the patterns of social media use by U.S. pharmacy schools and the size of the following audience.

Methods: All 135 pharmacy schools holding pre-candidate, candidate, accredited with probation, or accredited status with Accreditation Council for Pharmacy Education were included in the study. Each school's social media content was reviewed and recorded by 2 separate reviewers over a 3-week period (May 27 – June 15, 2016) to determine number of sites used as well as number of posts and likes specific to Facebook, followers for Twitter, and Instagram. Each school's number of applications, degrees conferred, and enrollees from 2014-2015 were collected. US News and World Report rank and score were collected and correlated to use of social media. Logistic regression was used to characterize the association of social media presence (had an account or not) while multiple regression was used to identify measures of social media attention (followers and "likes") and activity (posts and tweets).

Results: Twitter and Facebook were the most common social media platforms used. In total, 80% of pharmacy schools had a Facebook page, while 63% had a Twitter account and 27% had an Instagram. Roughly 16% of pharmacy schools had no social media presence whatsoever. Older universities were more likely to have Facebook and Twitter accounts. Facebook, Instagram, and Twitter account status was not correlated with number of applications. US News

and World Report score correlated with Facebook posts, Facebook likes, and Twitter followers. Additionally, Facebook likes had a moderate correlation with the number of applicants. Time from accreditation correlated with an increase in Facebook likes and Twitter followers.

Conclusion: Overall, a majority of pharmacy schools utilize social media in some format. Social media presence was seen in older pharmacy schools but did not show a correlation to the number of applicants. However, the attention (likes and followers) on some social media sites, especially Facebook, did have a moderate relationship to number of applicants and US News and World Report rank. Social media use by pharmacy schools is in its early stages of development and its value to these programs is still uncertain.

Poster Title: Suspected case of rivaroxaban-induced renal tubular acidosis

Primary Author: Bethannie Dziuk, University of the Incarnate Word Feik School of Pharmacy, Texas; **Email:** drzymala@student.uiwtx.edu

Additional Author (s):
Russell Attridge
Kathleen Lusk

Purpose: This case report describes a possible case of rivaroxaban-induced renal tubular acidosis (RTA) in a patient on long-term anticoagulation therapy for recurrent deep vein thrombosis (DVT). This patient began anticoagulation therapy with rivaroxaban 20 mg PO daily in 2013. She presented to the hospital in mid-2016 for left lower leg pain, which she attributed to a blood clot. DVT was ruled out using ultrasound. She was diagnosed with cellulitis and successfully treated with antibiotics. During admission, laboratory abnormalities prompted additional inpatient workup. Initial results from her serum chemistry panel were within normal limits except potassium (1.8 mEq/L) and bicarbonate (13 mEq/L) and her anion gap was normal at 11. The patient's magnesium and phosphate were normal at 2.1 mg/dL and 2.9 mg/dL, respectively. Her serum pH from a venous blood gas was 7.29. On the first three days of her hospital stay, the patient's potassium and bicarbonate remained low despite appropriate potassium replacement, and the etiology of her persistent hypokalemia and low bicarbonate remained unclear. After further chart review, we noted that her persistent hypokalemia and low bicarbonate had been present since 2013. In the setting of normal renal function, in addition to a normal anion gap metabolic acidosis without other apparent etiologies (e.g., diarrhea), these chronic deficiencies were concerning for a possible RTA. Our nephrology service was consulted for further workup. Her urine anion gap was variable, and the patient's urine pH rose from 6 to 7 after potassium citrate supplementation. Laboratory difficulties led to an unsuccessful bicarbonate challenge and the inability to calculate fractional excretion of bicarbonate (FEHCO3). Following potassium citrate replacement, her bicarbonate normalized. For the remainder of the hospital stay, she was supplemented with potassium citrate 20meq PO daily. On the day of discharge, all chemistry labs were within normal limits (potassium: 3.8mEq/L, bicarbonate: 25mEq/L). Because we were able to normalize her bicarbonate with a low dose of potassium citrate, and she persistently had a urine pH >5.3, it was determined she

most likely had a distal (type 2) RTA versus a proximal (type 1) RTA. RTAs are part of the differential diagnosis for patients with non-anion gap metabolic acidosis and are generally classified as inherited or acquired. Given its onset, inherited causes were determined to be unlikely. Acquired RTAs are often drug-related. Classic drug exposures for acquired RTA (acetazolamide, sulfonamides, ifosfamide, outdated tetracyclines, streptozocin, antiretrovirals) were not present, and multiple myeloma was ruled out with the absence of urinary light chains. A renal biopsy was not performed. The only major medical variable related to the onset of her chronic metabolic acidosis was the initiation of rivaroxaban in 2013. The Naranjo Algorithm, used to assess the probability of an adverse drug reaction (ADR) from rivaroxaban, gave a score of 3, indicting a possible ADR. Unfractionated heparin and related anticoagulants have been associated with hyperkalemic (type 4) RTA secondary to hypoaldosteronism; however, we were unable to find reports of heparin-like anticoagulants, or any other anticoagulants, causing hypokalemic (proximal or distal) RTA. While there appears to be a lack of plausibility of rivaroxaban causing RTA, a temporal relationship exists in this patient. When causes for a disease are unclear, clinicians must consider all potential causes for the disorder and proceed with treatment strategies that minimize risk to the patient. In this case, the risks and benefits of discontinuing/modifying anticoagulation versus treating the RTA with potassium citrate and continuing anticoagulation had to be determined. Given her current success with rivaroxaban, it was decided that continuing this agent for life-long anticoagulation outweighed the potential burden of daily potassium citrate supplementation.

Poster Title: Evaluation of interventions from a pilot antimicrobial stewardship program in a small community hospital

Primary Author: Kacey McQuiston, University of the Incarnate Word Feik School of Pharmacy, Texas; **Email:** mcquisto@student.uiwtx.edu

Additional Author (s):
Hien Ha
Nhi Bui

Purpose: Antimicrobial stewardship is becoming increasingly important due to increased resistance rates and increased risk for hospital acquired infections like Clostridium difficile. Christus Santa Rosa (CSR) Westover Hills is a 150-bed community hospital located in San Antonio, Texas. Due to increased Clostridium difficile rates and Centers for Medicare and Medicaid Services (CMS) requirements for a hospital based antimicrobial stewardship program (ASP), Christus established a collaborative, pharmacist led ASP. Stewardship initiatives included prospective antimicrobial surveillance and feedback, pharmacist decentralization, and hospital wide physician and nursing education. This study will evaluate the interventions recommended and accepted from the pilot ASP.

Methods: Based on prospective data collected from September 2015 to November 2015, a total of 209 interventions were recommended with 153 interventions accepted (73 percent acceptance rate). All interventions were classified according to categories and included: change in dose, change in route, change in interval, therapeutic drug monitoring, change in therapy, therapy de-escalation, and therapy discontinuation.

Results: Intervention categories that were among the most recommended and accepted were change in therapy (54/76 approved, 75 percent acceptance), therapy discontinuation (45/64 approved, 70 percent acceptance) and therapy de-escalation (33/54 approved, 61 percent acceptance). The intervention category least recommended and accepted was change in route (4/11 approved, 36 percent acceptance).

Conclusion: Although physician resistance was a problem, the initial phase of the ASP had an overall high acceptance rate on total recommended interventions. Pharmacist interventions with the highest acceptance rates can significantly impact antimicrobial prescribing through improving and de-escalating antibiotic selection and discontinuing unnecessary antibiotic usage. Christus Santa Rosa will definitely benefit from continued ASP efforts and our institution will pursue computer-based software to streamline workflow and improve efficiency and data collection.

Poster Title: Atrial fibrillation with new onset thromboembolism and previous major bleeds on warfarin and aspirin therapy: a case report

Primary Author: Deseree Reyna, University of the Incarnate Word- Feik School of Pharmacy, Texas; **Email:** dareyna@student.uiwtx.edu

Additional Author (s):
Jeffrey Van Liew
Bethany Kalich

Purpose: The case report illustrates the misperception of aspirin as a safe and effective antithrombotic therapy for stroke prevention in patients with atrial fibrillation (AF) and a history of major bleeding events. AG is a 63 yo female with a complex medical history of polycystic kidney disease (PCKD), deceased-donor renal transplant (2006), hyperparathyroidism, pulmonary vasculitis/diffuse alveolar hemorrhage (DAH), pulmonary hypertension, stroke (1999), gastroesophageal reflux disease (GERD), valvular, permanent AF (2005), mitral regurgitation (MR) status post mitral valve replacement (MVR), atrial septal defect closure (2007), osteoporosis, and as per patient "heart clot since the '90's" with no intervention. The patient has a history of two major bleeding events on antithrombotic and oral anticoagulant therapy (OAC): hemoptysis associated with warfarin initiation for new onset AF in 2005 and a gastric bleed associated with aspirin therapy initiated status post MVR in 2007. The patient underwent a routine outpatient transthoracic echocardiogram (TTE) on May 5, 2015, which revealed a large atrial mass. The differential included myxoma or thrombus. The patient was admitted on May 27,2015 for a transesophageal echocardiogram (TEE) to differentiate the mass. Appropriate stroke and systemic embolism (S/SE) prophylaxis was discussed on multidisciplinary rounds with consideration given to her CHA2DS2VASc score of 4 (age < 65, female, hypertension, stroke) and HASBLED of 3 (hypertension, stroke, prior major bleed). The pharmacy intern recommended OAC with warfarin, as opposed to aspirin, based on the proven superiority for S/SE prophylaxis and lack of added safety given an equivalent bleeding risk with aspirin (ASA) 325 mg daily. However, the cardiothoracic surgery resident elected to maintain use of the home aspirin 81 mg regimen given the concerns for bleeding. Afternoon report of the TTE revealed two large immobile masses deemed thrombotic in nature, though inoperable when considering safety and patient preference. Thus, OAC therapy discussions were re-visited,

with the pulmonologist weighing in on the risk of bleeding. Given the history of DAH, warfarin was recommended for long term therapy. The primary cardiology team felt most comfortable with a three-day-trial of intravenous heparin drip to allow close observation of potential bleeding. In light of no bleeding, warfarin 2 mg was initiated, for a goal therapeutic INR range of 2-3. Ultimately, the patient received warfarin, though this was a function of the active thrombus.The initial plan to use ASA 81 mg PO daily is not supported in the literature. The BAFTA (Birmingham Atrial Fibrillation Treatment) trial evaluated dose-adjusted warfarin (target INR 2-3) versus aspirin 75 mg/day in patients 75 years-of-age or older with AF or atrial flutter. Mant et al. found that warfarin reduced the risk of stroke (RR 0.46 (CI 0.26-0.79) p= 0.003) without increasing the risk of hemorrhage. Though target-specific oral anticoagulants (TSOACs) are not approved for valvular AF, the AVERROES (Apixaban Versus Acetylsalicylic Acid [ASA] to Prevent Stroke in Atrial Fibrillation Patients Who Have Failed or Are Unsuitable for Vitamin K Antagonist Treatment) 3 trial also demonstrated the considerable bleeding risk associated with aspirin use. In the AVERROES trial, patients with AF who were not candidates for warfarin received either apixiban 5mg BID or aspirin 81-324mg daily. Though terminated early, the study demonstrated lower rates of stroke with apixaban versus aspirin after one year (1.6%/yr vs. 3.7%/yr; 95% CI 0.32-0.62; P < 0.001) without a significant increase of major bleeding (1.4%/yr vs. 1.2%/yr; 95% CI 0.74-1.75; P=0.57). Considerable misunderstanding exists regarding the limited efficacy of and relatively significant bleeding risk of aspirin use, as compared to warfarin and even TSOACs. This case demonstrates the need for clear and accurate education regarding the limited role of ASA in S/SE prophylaxis for AF.

Poster Title: Incidence of Bleed in Cancer Patients Utilizing DOACs in an Emergency Center

Primary Author: Sitara Paladugu, UT Austin College of Pharmacy, Texas; **Email:** paladugu.sitara@gmail.com

Additional Author (s):
Tami Johnson
Maggie Ma

Purpose: Cancer patients are at greater risk of developing venous thromboembolism (VTE) due to increased tumor burden, procoagulant production and thrombogenic chemotherapy. They are also at greater risk for bleeding while using anticoagulants due to organ dysfunction/malnutrition. The CLOT trial illustrated the superiority of low molecular weight heparin (LMWH) over warfarin in cancer patients; thus, at our institution, LMWH is the primary treatment of choice. However, direct oral anticoagulants (DOACs) are an attractive alternative because of convenience, decreased monitoring and cost. The purpose of this study is to assess the incidence of bleeding in cancer patients who are on DOAC therapy.

Methods: The institutional review board approved this retrospective, single-center chart review utilizing the EPIC health records system. We randomized 150 patients from a pool of 14,000 patients on anticoagulants who presented to the emergency center (EC) between March and September of 2016. To be included in the study, patients needed to have a cancer diagnosis and be on current anticoagulation upon EC admission. Data was collected on cancer type, chief complaint, diagnosis and site of bleed, need for transfusion, kidney function, liver function, degree of thrombocytopenia and concurrent use of additional anticoagulants. A major bleed diagnosis was classified as a bleed in a critical region (e.g. intracranial, retroperitoneal) or the need for blood transfusion of ≥ 2 units of packed red blood cells. Minor bleeds were defined as anything not fitting the criteria for major bleed. Three groups of anticoagulants were examined: DOACs, LMWH, and warfarin.

Results: We collected data on a total of fifty patients for each group (DOAC, LMWH and warfarin). Within the DOAC group, 33 patients were on dabigatran, 11 patients were on apixaban and 6 patients were on rivaroxaban. Seven patients in the DOAC group (14%) met criteria for major bleed. The incidence of major bleed in the DOAC group broken down by specific drug was as follows: dabigatran, 6.1%; rivaroxaban 50.0%; and apixaban 18.2%. In the LMWH group, two patients (4%) were diagnosed with a major bleed. In the warfarin group, seven patients (14%) were diagnosed with major bleed. Minor bleeding occurred in 2% for DOACs (one patient on dabigatran), 2% for LMWH and 8% for warfarin.

Conclusion: In a retrospective analysis of patients on DOACs, enoxaparin and warfarin, we found that patients on warfarin and DOACs had a similar incidence of major bleed which was higher than LMWH. Based on a small sample, dabigatran seems to have the lowest incidence of bleed at 6.1%. The incidence of bleed between enoxaparin and dabigatran is similar,supporting its use in anticoagulation of cancer patients. Our data supports the results of the CLOT trial in which bleeding rates were higher with warfarin than with LMWH. Further studies are needed to assess the efficacy of DOACs for VTE treatment in cancer patients.

Poster Title: Literature review of available the appropriate treatment options for older women in Australia with atrial fibrillation.

Primary Author: Jeffrey Doornbos, University of Washington, Washington; **Email:** doornj@uw.edu

Additional Author (s):
Julie Byles
Meredith Tavener
Tazeen Majeed

Purpose: Develop a research background on epidemiology and treatment of atrial fibrillation among older Australian women. These women are at higher risk of stroke than men, and have a lower rate of receiving appropriate care compared with men. This review will combine global and Australian clinical guidelines and research to present current global and Australian treatment plans and identify some existing gaps in literature.

Methods: A database search was done to determine what comparative treatment options for atrial fibrillation, clinical guidelines, epidemiology, and gender comparison research exist. Search engines involved were Pubmed (Included Medline), Proquest, and Embase. Then an introduction, background, and gaps of evidence were developed.

Results: The following search terms were used to identify existing research: Arrhythmia, atrial fibrillation, Australia, women, stroke, and heart failure. Limiting terms involved were: full text, human, English language, year 1990 to current, and age greater than 65 years. From the search, 95 articles matched the search criteria and were analysed for relevance. Of that, 54 articles were referenced for the review.

Conclusion: Older women with atrial fibrillation are at higher risk of death compared to older men with atrial fibrillation. They also have a reduced quality of life when diagnosed compared to men. Gaps in research have been identified, and this will help in developing future studies.

Poster Title: Comparative Effectiveness of Agents Used as Monotherapy for the Treatment of Pulmonary Arterial Hypertension: A Systematic Literature Review and Network Meta-Analysis

Primary Author: Lauren Chin, University of Washington, Washington; **Email:** lchin@uw.edu

Additional Author (s):
Justin Yu
Beth Devine

Purpose: Network meta-analyses (NMAs) have previously been published to assess the comparative effectiveness of treatments for pulmonary arterial hypertension (PAH). However, not all studies included all marketed treatments for PAH nor did they assess the most common efficacy endpoint used in regulatory submissions – change in 6-minute walk distance (6MWD) from baseline to 12 weeks. 6MWD is a surrogate endpoint that reflects exercise capacity, is simple to measure and perform, and is also widely used in clinical practice to assess patient status. To date, a comprehensive NMA evaluating the comparative effectiveness of the various PAH-specific monotherapy agents has not been conducted.

Methods: We conducted a systematic literature review by searching MEDLINE and Embase for publications on PAH treatments. Abstracts were first reviewed independently by two investigators, with uncertainties or discrepancies resolved by consensus. Articles were then reviewed in full text by two investigators, with uncertainties or discrepancies resolved by consensus. Key inclusion criteria included: randomized, double-blind, controlled; majority of patients with PAH; study length ≥8 weeks; English language; average age ≥18 years; licensed therapy (i.e. Food and Drug Administration (FDA) or European Medicines Agency) for PAH or expected to be licensed shortly for PAH; appropriate dose based on prescribing information approved by the FDA; 6MWD as an outcome; monotherapy evaluated; and treatment-naïve. Key exclusion criteria included: drug withdrawn from market; assessed off-label treatment of PAH; assessed only hemodynamic, pharmacokinetic, or pharmacodynamic outcomes; non-human study; and patients transitioned from another treatment to a study treatment. Following the identification of all articles that met the inclusion criteria, patient demographics, clinical characteristics, and 6MWD at baseline and at 12 weeks were extracted into data tables. For articles in which key outcome data (e.g. mean values, standard deviations, or standard

errors) were not available, data were obtained from FDA medical reviews, a Cochrane review (Chen 2009), p-values, or using the GraphClick digitizer. Afterwards, data were analyzed using a frequentist approach with R version 3.3.1. Graphics were generated using STATA version 14.2.

Results: Eleven studies met all inclusion criteria and were included in the analyses. The PAH-specific treatments evaluated were ambrisentan oral (PO) 5 mg daily, ambrisentan PO 10 mg daily, epoprostenol intravenous (IV), bosentan PO 125 mg twice daily, riociguat PO maximum 2.5 mg three times daily, treprostinil subcutaneous (SC), treprostinil IV, sildenafil PO 20 mg three times daily, iloprost inhaled 2.5 or 5 micrograms 6 or 9 times daily, and placebo. Using a fixed effects model, results revealed a significant increase in 6MWD (meters) between each treatment compared to placebo. Between treatments, ambrisentan PO 10 mg daily and epoprostenol IV demonstrated a statistically significant increase in 6MWD compared to treprostinil SC (34.5 m (95% CI: 6.4 to 62.6 m) and 59.6 m (95% CI: 19.9 to 99.3 m), respectively). The I2 statistic was 35%, suggesting that heterogeneity was not significant. Using a random effects model, all treatments except bosentan PO 125 mg daily and treprostinil SC demonstrated a statistically significant increase in 6MWD (meters) compared to placebo. Between treatments, epoprostenol IV demonstrated a statistically significant increase in 6MWD compared to treprostinil SC (58.4 m (95% CI: 8.6 to 108.2 m)).

Conclusion: This is the first NMA to evaluate the comparative effectiveness of all marketed treatments for PAH as monotherapy and their effects on 6MWD from baseline to 12 weeks. Results from both the fixed effects model and random effects model consistently demonstrated that treatment with epoprostenol IV had a significantly greater increase in 6MWD compared to treprostinil SC. Relative to one another, other treatments were not found to be consistently better or worse in relation to 6MWD.

Poster Title: Development of clinical problem solving skills in first and second year student pharmacists: Patient case workshop pilot program

Primary Author: Arianne Duong, University of Washington School of Pharmacy, Washington; **Email:** arianned@uw.edu

Additional Author (s):
Marian Dobles
Nanci Murphy
Douglas Black

Purpose: In the first two years of their academic training, pharmacy students at the University of Washington learn predominantly through didactic coursework, and opportunities for application of course material are limited during this time. However, given the challenging realities of practice, pharmacists must effectively apply their knowledge, skills, and prior experiences in a variety of complex situations that may change rapidly and unpredictably over time. The purpose of the Patient Case Workshops was to provide first and second year PharmD students an opportunity to actively engage in the clinical reasoning and decision-making process with guidance and feedback from experienced practitioners.

Methods: The Patient Case Workshop program was organized and piloted by two pharmacy students with the guidance of two University of Washington School of Pharmacy faculty members. Patient Case Workshops consisted of a total of fourteen sessions, supervised by practicing pharmacists or pharmacy residents who assumed the role of workshop facilitators. Workshop facilitators guided students through the thought process behind the assessment and development of a plan for a patient that they helped treat in their practice. Workshop topics included: asthma, cardiology, diabetes, pain, pediatrics, neurology, and oncology.
First, second and third year students were invited to participate, with a focus on second year student pharmacists during both years of the pilot program. Students engaged and actively participated in the discussions to facilitate their learning. Students asked questions to collect information, clarify diagnoses, and increase their baseline knowledge about medication regimens. Students prepared assessments and plans within a small group format to come to potential solutions, and had the opportunity to present them. An inter-professional component

was included in two cases, with students from the schools of Nursing and Social Work taking part in active small-group discussions with pharmacy students.

At the end of the first year of the pilot study, a survey was distributed to participating students to assess the viability of continuation of the project into its second year.

Results: During the first year, 206 participants attended one or more workshop sessions, with an average 25 students per session. In the second year of the project, 256 participants attended, with an average of 32 students per session. Most students participated in more than one session. In addition, during the first year, 70% of participants were PY2s and the remaining 30% were PY1s. During the second year, invitations to participate were also extended to third year students to further integrate the topics learned in therapeutics, although the focus remained on PY2s.

In the survey that was sent to participants at the end of the first year, a total of 18 students responded. 88% of survey respondents answered "yes" when asked if they would register for an elective course that offers workshops once per week. When asked what the sessions helped students improve on the most, top answers included "knowledge of the subject" and "exposure to the role pharmacists play in a healthcare team."

Conclusion: Patient case workshops allow students to solidify and utilize didactic coursework, provide an opportunity to self-assess abilities to apply knowledge in a practical setting, help students to identify pertinent information necessary to assess a patient, and provide practice opportunities to formally present a plan. Based on the results of the participant survey and general popularity of the sessions, we conclude that by involving practitioners and integrating clinical reasoning/problem-solving opportunities early in the curriculum, opportunities such as patient case workshops help support and deepen student learning.

Poster Title: Evaluation of the utilization of ranolazine at an academic hospital system

Primary Author: Mercy Hoang-Nguyen, University of Washington School of Pharmacy, Washington; **Email:** mercyhn@uw.edu

Additional Author (s):
Carly Bliss
Beatrice Wong

Purpose: Ranolazine (Ranexa®) is FDA approved for treatment of chronic angina in patients unresponsive to 1st line agents. It is also used off label for persistent atrial and ventricular arrhythmias in patients unresponsive to 1st line therapies. Inappropriate use of ranolazine can lead to unwanted harm and financial burden for patients. This project evaluated the prescribing practices with ranolazine based on current FDA approved and off-label indications at the University of Washington and Harborview Medical Centers over a 6-month period. This project also characterizes drug interactions with common concomitantly used medications and evaluates if adjustments were made as appropriate.

Methods: Ranolazine use between November 1, 2015 and April 30th, 2016 was identified through pharmacy dispensing records. Inclusion criteria included patients that charted administration of at least one dose in that time period. A retrospective chart review in ORCA PowerChart (Cerner) was then conducted. Dosing, indications for use (FDA approved and off-label) and status of home ranolazine continuation were evaluated for all patients. Continuation of home 1st line agents (beta blockers, calcium channel blockers and nitrates) was also evaluated for patients who received ranolazine as treatment for chronic stable angina. For patients who received concurrent CYP3A inhibitors during their course of treatment with ranolazine, charts were further reviewed to identify any efforts to mitigate, minimize or monitor potential complications as recommended by the manufacturer.

Results: 65 patients received ranolazine at the University of Washington and Harborview Medical Centers during the study period. There were 104 hospital admissions among these 65 patients. Ranolazine was appropriately prescribed for FDA approved and common-practice off-label indications for all admissions. Ranolazine was used for chronic stable angina in 67

admissions, and for ventricular tachycardia in 37 admissions. Of the chronic stable angina encounters, 66 showed continuation of home 1st line agents. Only one patient during one admission received an inappropriate dose of ranolazine without adequate documentation of intervention or monitoring regarding the high dose dispensed. The other 64 patients received appropriate dosing during 103 hospitalizations as recommended by the manufacturer for chronic stable angina and according to conducted clinical trials for ventricular tachycardia. Ranolazine was a prior-to-admission medication continuation in 78 of 104 admissions. During 35 admissions, ranolazine was concomitantly administered with moderate CYP3A inhibitors often prescribed in these disease states. Dose adjustments occurred in 11 of these instances; clinical monitoring was not noted in provider documentation when no dose adjustments were made.

Conclusion: The University of Washington and Harborview Medical Centers appropriately prescribed ranolazine for FDA approved and off-label indications. In most cases, inpatient use was a continuation of home ranolazine. Lack of dose adjustment with concomitant use of CYP3A inhibitors may suggest the need for an automated alert or pharmacist intervention when prescribers are not aware of drug interactions.

Additional Author (s):
Christina Bockman
Amy Munekiyo

Purpose: Lidocaine 5% patches (Lidoderm®) are FDA approved for pain associated with post-herpetic neuralgia (PHN). However, at Harborview Medical Center (HMC), they are often prescribed for various off-label acute and chronic conditions. This off-label use can become problematic for patients post-discharge, as many insurance companies do not pay for lidocaine patches for off-label indications. This study compared the cost-effectiveness of lidocaine patches to established, first-line pain medications for most commonly used indications within our institution. This study also characterized the prescribing of lidocaine patches based on indication and which medical services had the highest rates of prescribing.

Methods: Pharmacy dispensing records from April 1, 2016 to April 30, 2016 were used to identify patients initiated on lidocaine 5% patches at Harborview Medical Center. All patients that were admitted during this time period and received at least one lidocaine 5% topical patch during their stay were included in this study. Patients excluded during this time frame included those admitted to the Emergency Department, those that were discharged prior to being admitted to the floor, and those that were discharged outside of the above time frame. Of the 116 patients meeting the inclusion criteria, 30 patients were chosen by a random number generator and these charts were retrospectively reviewed. Data collection included the hospital service that prescribed the lidocaine patch, total number of days in the hospital, total number of doses or lidocaine patches received, cost of lidocaine patch therapy, and prior and/or concurrent use of other pain modalities.

Results: The patients in this study consisted of 13 females (43.3%) and 17 males (56.7%), with an average age of 56.5 years (range 21-104 years) and an average length of stay of 12.2 days (range 3-43 days). Within this patient selection, there were a total of 241 patches dispensed and administered, resulting in a total cost of $6,230. The average cost of lidocaine patches per patient per admission was $208 and the average cost per day per patient was $17. The Medicine service prescribed patches for 13 patients (43.3%), General Surgery Trauma prescribed for 6 patients (20%), Neurosurgery prescribed for 4 patients (13.3%), Medicine Cardiac Care Unit (CCU) prescribed for 3 patients (10%), and Acute Pain Service(APS), Trauma Surgery ICU, Orthopedics, Rehab Medicine prescribed for 1 patient each (3.3% each). Two patients (6.7%) were prescribed lidocaine patches prior to admission and nine patients (30%) were discharged with the patch. All patients were found to be using other pain modalities prior to initiation of the patch. Indications included back (33.3%), rib (16.7%), neck (14.3%), and chest pain (14.3%), pain at multiple sites (14.3%), and other pain (10%). None of the patients were prescribed lidocaine patches for PHN.

Conclusion: This retrospective study showed that the Medicine service is largely responsible for prescribing most of the lidocaine patches within this institution. The most common indication for prescribing was back pain and none of the patients were prescribed lidocaine patches for the FDA approved indication of PHN. Although the cost of lidocaine patches is more expensive than oral and intravenous pain modalities, it is difficult to determine if this correlates with better outcomes and patient satisfaction as other pain modalities are used concurrently with administration of the patch. This data provides a benchmark for future quality improvement studies and comparisons.

Poster Title: Impact of pharmacy-driven patient education on heart failure hospitalizations

Primary Author: Rosannara Chhun, University of Washington School of Pharmacy, Washington; **Email:** rchhun@uw.edu

Additional Author (s):
Michael Schirmer

Purpose: Clinical pharmacists improve disease state management for a variety of conditions, including hypertension, diabetes, and congestive heart failure (CHF). Despite these clear benefits, direct pharmacy involvement remains inconsistent throughout healthcare systems and has yet to evolve as the standard of care for heart failure patients. While multidisciplinary practice is advocated by heart failure treatment guidelines, there remains a paucity of literature endorsing the pharmacist's role in transitional care. The primary objective of this study is to evaluate the significance of a pharmacist or graduate pharmacy student reviewing medications and providing counseling at discharge with subsequent effect on readmission rates.

Methods: The pharmacist and pharmacy student provided interventions such as patient education, prescribing heart failure medications using a collaborative practice with providers, monitoring drug concentrations, medication reconciliation, and ensuring treatment adherence. The pharmacy student performed a retrospective cohort study of patients seen by Swedish Advanced Cardiac Support. Data was collected in two sets, one year before and nine months after a pharmacist joined the CHF clinic team in September 2015. The primary endpoint studied was the 30-day readmission rates. Inclusion criteria comprised of adult patients greater than or equal to 18 years of age, patients with a diagnosis of ICD 10 code I50, or patients who were admitted to or consulted by Swedish Advanced Cardiac Support Program. Exclusion criteria included pediatric patients less than 18 years of age and prisoners. Subjects were stratified into two groups, those who received pharmacy-led counseling at discharge versus standard of care, largely nurse or provider-led counseling.

Results: From September 2014 to September 2015, there were 420 CHF cases. Of these cases, 39 patients were readmitted within 30 days. The readmission rate at Swedish Medical Center during this time period was 9.29 percent. A pharmacist was present to provide the appropriate

interventions between October 2015 and June 2016. During this time, there were 324 CHF cases with 27 patients who were readmitted within 30 days. The readmission rate at this time was 8.3 percent. Although the readmission rate dropped by 1.01 percent, the chi-square test did not prove to be statistically significant with a p value of 0.65. Several limitations were identified in this process, including a small sample size, short time period, and restricted roles of the pharmacist, as it was a brand new position. These limitations have lead to various improvements in the patients' transition of care, such as identifying potential barriers to treatment success and resolving them by providing full medication reviews, completing physical exams, smoking cessation counseling, managing hypertension and hyperlipidemia as well as obtaining medication insurance approvals.

Conclusion: Utilizing the pharmacist's skills to provide patients with a better understanding of their disease and medications could prevent medication error and increase treatment adherence throughout transitions of care and reduce the need for hospitalization. However, the involvement of the multidisciplinary team is integral to a patient's improvement in disease management. Further steps to improve this process are to obtain data from a longer period of time, establish the pharmacist's roles and responsibilities, promote interdisciplinary collaboration, and integrate site visits to patient's homes.

Submission Type: Evaluative Study

Session-Board Number: 2-420

Poster Title: Aspirin resistance in pediatric patients after cardiac surgery

Primary Author: Nan Julius, University of Washington, School of Pharmacy, Washington; **Email:** naye@uw.edu

Additional Author (s):
Christa Kirk

Purpose: Pediatric patients undergoing cardiac surgery are at high risk for thrombosis, especially neonates, those with single ventricular anatomy, and prolonged insertion of central venous catheters. Aspirin is commonly used as antiplatelet therapy to prevent thrombosis after high risk cardiac procedures. Aspirin resistance has been reported in pediatric patients with cardiovascular defects undergoing surgical procedures. The goals of this quality improvement study are to elucidate the characteristics of aspirin resistance in pediatric patients undergoing cardiac surgery and to determine if a dose-response relationship exists between aspirin and aspirin reaction units.

Methods: This was a prospective study using the VerifyNow Platelet Inhibition Assay to assess platelet function in patients receiving aspirin for thrombosis prevention. Inclusion criteria were: (1) patients requiring post-surgical anticoagulation with aspirin after cardiac surgery and (2) age less than 18 years. Results were based on aspirin reaction unit (ARU) values. ARU values less than 550 indicate aspirin-induced platelet inhibition. ARU values greater than 550 indicate lack of aspirin-induced platelet inhibition. The starting dose of aspirin was 5 milligrams per kilogram per day (mg/kg/day). If a patient's ARU remained greater than 550, indicating inadequate response, the dose was incrementally increased up to 13 mg/kg/day (maximum 325 milligrams per day). Baseline hematocrit and platelet count were obtained and repeat platelet counts were assessed 3 to 10 days post initiation of aspirin. Exclusion criteria were: (1) platelets less than 50,000 per microliter, (2) hematocrit less than 20 percent, (3) administration of additional antiplatelet agents, or (4) documented thrombosis before administration of aspirin therapy.

Results: This is a preliminary study to detect the presence of aspirin resistance in pediatric patients undergoing cardiac surgery. There were 7 pediatric cardiac surgery patients included in this study. The age range was 2 weeks to 6 months, with the median age being one month. The

dose range was 3.10 to 12.85 mg/kg/day (mean 7.52). Five of seven patients (72 percent) responded to standard aspirin therapy, while two of seven patients (28 percent) required higher aspirin doses due to ARU levels greater than 550. Of those requiring dose increase, one patient had an ARU less than 550 after dose increase to approximately 13 mg/kg/day. The other had a persistent ARU level greater than 550 even after dose increase and developed a lower extremity thrombosis requiring anticoagulation with low molecular weight heparin. One patient was excluded from the study due to the development of necrotizing enterocolitis during therapy, necessitating discontinuation of the aspirin.

Conclusion: Aspirin resistance exists in pediatric patients undergoing cardiac surgery. In some patients, aspirin resistance can be overcome by dose escalation. Thrombosis was seen in one patient who demonstrated aspirin resistance despite receiving a higher dose of aspirin.

Poster Title: Influence of Age on Patient Education of Anticoagulation Therapy using Warfarin

Primary Author: Thao Nguyen, Washington State University, Washington; **Email:** thaok.nguyen@wsu.edu

Additional Author (s):
Kelly Groth
Angela Armstrong

Purpose: Warfarin is a widely used anticoagulant medication with significant therapeutic benefits. Anticoagulation is also one of the medication classes with the highest risks profile. Managing warfarin to achieve the maximum therapeutic benefit can be challenging for both provider and patient. This 3-week retrospective observational study was used acquire a baseline evaluation of whether a patient's age has any impact on their understanding of warfarin therapy. The information gathered will be used to develop effective education plans and target age group that struggle most with understanding the use and risks of their warfarin therapy.

Methods: The study enrolled new patients from one anticoagulation clinic: Memorial Cornerstone Anticoagulation Clinic,in Yakima, WA, over a 3-week period between June 6- June 24, 2016. Patients at their first visit were given a 30 minute educational appointment performed by varying pharmacists. This clinic followed its own protocol for dosing and education adapted from the 2012 CHEST guidelines.
New patients are defined as having visited the anticoagulation clinic more than 1 visit but no more than 5 visits or have been at the anticoagulation clinic within a 2 week period, whichever is greater. These patients were given a questionnaire adapted from the Managing Oral Anticoagulation Therapy: Clinical and Operational Guidelines and their results were recorded. The questionnaire was written in layman's term with the exception of using the term INR. The primary objective was to determine if at least one age group would perform better or worse than the other age groups in the study. The secondary objective was to determine which concept and question patients had the greatest difficulty understanding.

Results: Patients who met the criteria were enrolled, 32 patients qualified with 4 (13%) patient were restarting. Patients restarting therapy moved away and recently returned or were at this clinic but started being managed elsewhere and returned. Patients who are classified as restart had not been to the clinic greater than one year. The clinic was opened Monday-Friday 8:30-5pm with a 24 hour on call pharmacist. Patients were placed into one of five age groups "Under 50", "50-59", "60-69", "70-79", "Over 80". An anova test was performed yielding a p-value 0.19. The null hypothesis states that at least one of the means is different and the alternative hypothesis states that all groups would yield the same score. We fail to reject the null hypothesis. For the secondary endpoint, all groups struggled with, "What will happen to my INR if I eat too many Vitamin K rich foods?" 56% of patients answered the question incorrectly. There are several limitations to this study. The time frame was narrow causing a small sample size to participate in this study. The questionnaire included only English speaking patients. The data gathered was limited to one clinic.

Conclusion: Clinicians should be aware that many patients receiving oral anticoagulation therapy have significant gaps in their warfarin-related knowledge, even after receiving initial education and frequent monitoring through an anticoagulation clinic. It is advisable to assess patients' knowledge, beliefs and practices. Frequent reinforcement of key information and "refresher" educational materials should be offered periodically throughout therapy. Future studies may include a longer time frame to increase the sample size, performing further observational studies to find a correlation between better patient education and better control with anticoagulation therapy, and or if better patient education relates with less adverse effects.

Submission Type: Evaluative Study

Session-Board Number: 2-422

Poster Title: Evaluation of highly active antiretroviral therapy (HAART) adherence in an independent pharmacy

Primary Author: Amanda Wright, Washington State University, Washington; **Email:** amanda.wright@wsu.edu

Additional Author (s):
Megan Willson

Purpose: Adherence to highly active antiretroviral therapy (HAART) is extremely important when treating human immunodeficiency virus (HIV), as replication of the virus must be suppressed to prevent opportunistic infections and progression to AIDS. This virus is known to have a high mutation rate, particularly when medications aren't taken appropriately, which can result in resistance to medications. The objective of this project was to assess adherence rates to HAART medications and the impact of home medication delivery at an independent community pharmacy in Washington.

Methods: The WSU Office of Research Assurances has found that the project is exempt from the need for IRB review. All patient profiles were de-identified and a review was conducted for HAART medications from January through June of 2016. All prescriptions were for a 30 days supply. Adherence was determined by reviewing pick-up dates for each medication and calculating the excess or deficit at the time of the next fill. For the purpose of this study, it was assumed patients had no medication on hand as of the first pick-up date, day 1. Each patient was also assumed to take the first dose of medication on day 1, and the last dose on day 30. Adherence rates for the course of therapy were calculated using two methods: total months supply of medication from the month of first pick-up through June, and total days covered from first pick-up to day 30 from the final June prescription. Days supply for subsequent fills was counted from the day after day 30. Deficit from late pick-up was calculated by counting from the day after day 30 to the day before the next fill. Early pick-up, resulting in medication surplus, was accounted for by counting from the early pick-up date through day 30 of the current fill. Delivery method was also compared to adherence rates to determine effects on adherence.

Results: Nineteen patients' HAART therapy was reviewed for adherence to prescribed regimens. The patient population included 15 males and 4 females, ages 21-60. The average adherence rate based on months supply was 120.2 percent, while the adherence rate for total days covered was an average of 115.7 percent. Patients with medication deficit had an average adherence rate of 86.4 percent in months supply, and 87.8 percent total days supply. The average adherence rate for patients with medication surplus was 129.2 percent from months supply, and 123.2 percent total days supply. The recommended HAART adherence rate of 95 percent was met by 84.2 percent (16/19) of patients. Method of delivery was analyzed along with adherence rates. Of the study population, 10 received their prescriptions by mail, and 9 picked up their medications from the pharmacy. Upon analysis, 90 percent (9/10) of mail delivery patients received all prescriptions on time, with an average months adherence of 139.9 percent, and average total days supply adherence of 131 percent. Only 22.2 percent (2/9) of patients picking up from the pharmacy received all prescriptions on time, with a months adherence average of 98.2 percent, and an average total days supply adherence rate of 98.8 percent.

Conclusion: Overall medication adherence in this project was very good. Methods of delivery influenced the adherence rates of the individuals in this pharmacy. Options for mail delivery provided by this independent pharmacy is helping to ensuring their HIV patients receive their medication on time each month.

Poster Title: Incorporating patient education guides to improve thirty day readmission rates for patients with chronic obstructive pulmonary disease

Primary Author: Kelly Artiga, Washington State University, Washington; **Email:** kelly_lizeth@wsu.edu

Additional Author (s):
Tara Kamprath

Purpose: Chronic obstructive pulmonary disease (COPD) is a complicated disease state that is often poorly controlled due to lack of patient understanding. According to the United States government site for Medicare, the national rate of readmission for COPD patients is twenty percent. This institution is no different than the national average readmission. The purpose of this study is to improve patient compliance with COPD disease state management through identification of knowledge deficits and implementation of patient specific education at the bedside.

Methods: Prior to the study, COPD readmission data was obtained from the data and informatics manager of the institution. A committee was established with respiratory therapists and pharmacists to approach a consensus on what needed to be accomplished to improve outcomes. Four main educational objectives were established: understanding the pathophysiology of COPD, knowing proper inhaler technique including the difference between rescue and maintenance medications, identifying how triggers and allergens play a role in COPD, lastly, recognizing when to seek urgent medical attention. To understand what educational needs a patient requires, a patient assessment was developed based on the four patient objectives. The answers were then used as a guide for discussion that both pharmacy and respiratory therapy could use at the bedside. Additionally, a student pharmacist developed a medication educational tool that personalized regimens by indicating exactly what medications the patient is discharging on, whether that medication is intended for rescue or maintenance and why that medication is important. The educational insert includes a calendar that can be used for an oral steroid taper and a green, yellow, red zone table that identifies an appropriate action plan for the patient based on current symptoms.

Results: From January of 2012 to August of 2016 there have been 1707 primary diagnosis of a COPD exacerbation. In this time frame, 40 of our patients were readmitted in less than thirty days. Eight respiratory therapists, five pharmacists and twenty pharmacy students have successfully passed the initial assessment that would be given to patients to fill out. The pharmacy director and clinical managers believe the COPD patient assessment is a useful tool to identify possible disparities in knowledge, guide patient specific education and improve readmission rates.

Conclusion: Thirty day readmission with complicated disease states is something that several institutions are trying to improve nationwide. The COPD patient assessment will help identify disease state knowledge deficits, which will in turn guide patient specific educational needs. Implementation of this educational tool and process will help standardize our institutional approach to COPD patient education in addition to improving patient compliance and successful disease state management outside of the hospital.

Poster Title: International advanced pharmacy practice experience (APPE) in Ecuador: prevalence of arthritis in Ecuadorian Andes mountains

Primary Author: Yedesdes Shiferaw, Washington State University, Washington; **Email:** yshiferaw@wsu.edu

Additional Author (s):
Natasha Heimbigner

Purpose: Arthritis has been one of the most common diagnoses in the villages of the Ecuadorian Andes mountains based on the previous medical mission data. The aim of this study was to determine the prevalence of arthritis in patients that were seen at the free clinic in the villages of Basan Grande, Cebadas, and Panchancho, Ecuador. Furthermore, to help future medical mission trips determine the amount of medications will be needed to provide effective treatment for arthritis and medical services.

Methods: Every year the fourth year pharmacy students travel to Ecuador with the Ecuador Medical Mission Team/One Heart Global Ministries to set up free medical clinics in different villages as part of fourth year APPE rotations. Patients were seen by healthcare providers; physicians, surgeon, medical students, pharmacist, and nurses based on first come, first-served basis. The study was conducted between the months of July-August 2016 in three villages of Ecuador: Basan Grande (n equals 210), Cebadas (n equals 388), and Panchancho (n equals 132). Patients were diagnosed with arthritis based on physical exam and symptoms of arthritis. Patients with arthritis were identified and analyzed to estimate overall arthritis prevalence by village and gender groups.

Results: A total of 731 patients were evaluated and 108 of these patients were diagnosed with arthritis. The overall prevalence of arthritis in the three villages was 15 percent, 61 percent of women, and 39 percent of men. In Basan Grande the prevalence of arthritis was 18 percent, 65 percent of women and 35 percent of men. The prevalence of arthritis in Cebadas was 17 percent, 72 percent of women, and 28 percent of men. In Panchancho the prevalence of arthritis was 3 percent, 100 percent of them were women.

Conclusion: The study showed 15 percent of the populations that were seen at the remote clinic were diagnosed with arthritis. The prevalence of arthritis was significantly higher in women compared with men. This finding shows arthritis as one of the highest diagnoses. Future healthcare providers should provide education on osteoporosis and dispense more calcium and vitamin D. Additionally, focus on patient education on prevention of arthritis such as exercising and eating a healthy diet.

Poster Title: Evaluation of sugammadex use compared to neostigmine in a community hospital

Primary Author: Angela Armstrong, Washington State University College of Pharmacy, Washington; **Email:** angela.armstrong@wsu.edu

Additional Author (s):
Alyssa Nii

Purpose: Within a few months prior to this study, sugammadex was added to the hospital's formulary and carried in all operating rooms' medication dispensing apparatuses. The purpose of this study was to evaluate sugammadex use and subsequent cost compared to neostigmine, which was previously the medication of choice, for the reversal of neuromuscular blockade during surgeries.

Methods: This was an evaluative retrospective study of all patients treated with sugammadex in a community hospital from July 15, 2016 to August 17, 2016. The list of patients was provided by the pharmacy department. Patients' computerized medical records were reviewed and the data collected included: age, gender, weight, sugammadex package size used and quantity administered, and severity of kidney disease if applicable. From this data, an equivalent neostigmine dose (based on recommended dosing of 0.03 mg/kg) and administration quantity was calculated. Sugammadex administration doses were calculated from patient weight and administration quantity for analysis of proper dosing based on recommendations per sugammadex prescribing information. Pharmacy purchasing prices for the 2 mL and 5 mL vials of sugammadex (100 mg/mL) and 10 mL vials of neostigmine (1 mg/mL) were obtained, costing $88.84, $162.73, and $58.69, respectively, and used to extrapolate cost differences between the two medications for each patient encounter. It was determined that 1 vial of neostigmine would have been used for each patient encounter, the remainder would then be wasted; it is important to note that sugammadex is only available in single-use vials.

Results: A total of 36 patients were evaluated, with 23 being under the age of 65. There were 20 women (ages 17-90) with an average weight of 87.28 kg and 16 men (ages 23-90) with an average weight of 95.11 kg. There were no patients with severe kidney disease and only 1 patient with moderate disease. It was determined that the cost difference between a 2 mL and

5 mL vial of sugammadex, when compared to a 10 mL neostigmine vial, was $30.15 and $104.04, respectively, resulting in a total loss of $1528.74 during this time period, or $42.47 per patient encounter. According to the dosing recommendations of the sugammadex prescribing information of 2 mg/kg or 4 mg/kg, there were 8 instances where these recommendations were not followed; the majority (7 out of 8 patients) resulted in under-dosing.

Conclusion: Only direct drug acquisition costs for the pharmacy were evaluated, in which case, neostigmine was more costs-saving than sugammadex at approximately $42.27 per patient encounter. In addition, this analysis found that some patients did not receive appropriate doses of sugammadex. This analysis did not look into extraneous costs such as those associated with recovery time, operating room costs, or insurance reimbursement. Further study must be completed to fully grasp the extent of costs associated with the use of sugammadex compared to neostigmine and to assess the effects of under-dosing patients receiving sugammadex for neuromuscular blockade reversal.

Submission Category: Preceptor Skills

Submission Type: Descriptive Report

Poster Title: Regionalization of pharmacy student programs at Southwest Washington Region Providence facilities with utilization of the layered learning practice model: a process improvement project

Primary Author: Savannah Kolterman, Washington State University College of Pharmacy, Washington; **Email:** savannah.kolterman@wsu.edu

Additional Author (s):
Michael Marr
Danny Veenhouwer
Dominick Caselnova

Purpose: In 2011, the American Journal of Health-Systems Pharmacy published The consensus of the Pharmacy Practice Model Summit which emphasized the importance of a patient's right to pharmacists' care. In 2015, a publication discussing the issues pharmacy leaders faced included practice model growth and the role of students among the top concerns. The layered learning practice model (LLPM) assists in fulfilling the clinical and educational needs in hospital pharmacy. Our goal as a region is to increase direct patient interaction by clinical pharmacists while providing a remarkable learning experience for students and residents with the implementation of this model.

Methods: The Southwest Washington Providence pharmacy team has been working to rapidly grow our clinical services, student rotations, and residency program over the past 4 years. As of 2016, we employ 45 full-time pharmacists, offer 127 student rotations, and accept 10 PGY1 residents, making us exceptional candidates for the implementation of the LLPM. This project was designed to assess the perceived current performance of our LLPM. A 10 question survey comprised of a Likert scale was prepared and arranged from 0 to 5, with 0=not applicable, 1=strongly disagree, 2=disagree, 3=neutral, 4=agree, and 5=strongly agree. Pharmacists with an active preceptor license who had experienced the LLPM were provided the anonymous survey via email and were given 14 days for completion. This survey assessed: preparedness to participate in the LLPM, appropriate allocation of tasks to both residents and students, adequate time to complete clinical tasks while precepting, removal of order verification from clinical service lines, amount of direct patient care achieved with the LLPM, satisfaction with

amount of direct patient care time achieved, and the satisfactory education of students on medication safety and transitions of care. The pharmacists also had the opportunity to leave additional comments along with their scoring. The results were then collected and tallied.

Results: A total of 26 pharmacists completed the survey within the 14-day period. All responses ranking from 1-5 were included in the analysis. Preparation for the implementation of the LLPM was felt to be adequate by 38% pharmacists while the remainder did not feel there was enough training. 26% of pharmacists surveyed agreed that more direct patient care is accomplished with the use of students and residents, while 74% did not agree with this statement. Currently, 54% of the pharmacists are satisfied with the amount of direct patient care they are achieving. While 32% of pharmacists agreed that they have enough time for educating students and residents while completing their clinical tasks, the remainder did not agree. There were 9 comments similarly describing the relationship between amount of direct patient care/clinical services achieved and the amount of time a student or resident had spent at that rotation. The beginning of each rotation requires more commitment to orientation and education at the potential expense of clinical services. This is in contrast to the end of each rotation which often culminates in more provision of patient care from the pharmacist, resident, and student team.

Conclusion: Based on these results, the execution of the LLPM at Southwest Washington Region Providence facilities has room for growth and improvement. More than half of the pharmacists surveyed did not feel adequately prepared to execute the LLPM, which suggests more time must be invested in preceptor development to achieve optimal utilization of students and residents. Unfortunately, the majority of pharmacists surveyed do not feel this model has improved time for clinical services or direct patient care. Although our goal has not yet been reached, these results expose the opportunities for future development and refinement of the LLPM at our facilities.

Submission Category: General Clinical Practice

Submission Type: Descriptive Report

Session-Board Number: 2-427

Poster Title: Evaluation of occurrences and causes of hypoglycemia to identify ways pharmacists may intervene to decrease incidences of hypoglycemic events associated with antihyperglycemic agents

Primary Author: Hope Tran, Washington State University College of Pharmacy, Washington; **Email:** hope.tran@wsu.edu

Additional Author (s):
Jill Miller
Brent Albertson
Lance Muncey

Purpose: Hypoglycemia in the hospital is associated with increased mortality and increased length of stay. The American Diabetes Association recommends a target glucose range of 140 to 180 mg/dL for the majority of critically ill and noncritically ill patients, a less stringent goal than at home. Patients often get restarted on their home regimen of insulin and/or oral antihyperglycemic agents without maintaining the diet they had outside of the hospital. Coupled with acute sickness, patients are at higher risk for hypoglycemia. This project aims to evaluate hypoglycemic events to identify ways for pharmacists to intervene in decreasing the number of events.

Methods: An electronic screening tool was used to identify patients who had hypoglycemia, defined in this project as a blood glucose less than or equal to 60 mg/dL. An event was defined as low blood glucose of 60 mg/dL or less including all the lows afterwards that are related to the same cause. Data was collected over a period of 4 weeks. Information that was looked at included: antihyperglycemic regimen, steroid use, causes of each event, changes made to insulin regimen after a hypoglycemic event and prevalence of hypoglycemia in each medical service. After meeting with the head physician of the diabetes team at Providence Sacred Heart Medical Center, insight was given on how pharmacists may intervene. This project is Institutional Review Board exempt because it is performance improvement.

Results: In a 4 week time period, 84 patients experienced at least 1 hypoglycemic event; 26 patients' hypoglycemia was not associated with antihyperglycemic agents, while 58 patients were diabetic and/or had at least 1 antihyperglycemic agent. These 58 patients accounted for 86 total events in the 4 week time period. Long acting insulin was identified as the causative factor in 39 of the 86 events (45 percent). In only 55 out of the 86 events (64 percent) was a change made to the antihyperglycemic regimen after a low blood glucose was recorded; the median basal insulin reduction was 25 percent in patients that had a change made. There were 2 hypoglycemia events related to discontinuation or dosing frequency of steroids. Of the 58 patients who had at least 1 hypoglycemic event associated with an antihyperglycemic agent, 12 patients were on the cardiac medical floor, which is consistent with previous reports of hypoglycemia at this institution.

Conclusion: Pharmacists have a role in inpatient hypoglycemia by being medication experts as well as through daily conduction of thorough medication profile reviews. Pharmacists may aid physicians and hospitalists by identifying patients at high risk for a hypoglycemic event and making recommendations to an antihyperglycemic regimen. Through this initial evaluation, a follow-up pilot project will be implemented on the cardiac medical floor in which pharmacists will make recommendations regarding restarting home antihyperglycemic regimens, adjusting a regimen based on steroids and antihyperglycemic dose/regimen change after a low blood sugar has been recorded to prevent a recurrence.

Submission Category: Practice Research/ Outcomes Research/ Pharmacoeconomics

Submission Type: Descriptive Report

Session-Board Number: 2-428

Poster Title: A survey of physicians, physician assistants and student pharmacists satisfaction: Utilizing student pharmacists to identify medication prior authorizations

Primary Author: Lillian Chi, Washington State University College of Pharmacy, Washington; **Email:** lillian.chi@wsu.edu

Additional Author (s):
Kathryn MacCamy
Chris Greer

Purpose: The purpose of conducting this satisfaction survey was to assess the implementation of a pilot prior authorization service led by student pharmacists. Our primary objective by initiating this new service at St Luke's Rehabilitation Institute in Spokane, WA was to identify patients preparing for discharge and ensuring medications requiring insurance prior authorization were identified. Processing these requests require hours to weeks worth of communication and documentation between physicians, physician assistants, and insurance companies. By utilizing Advanced Pharmacy Practice Experience (APPE) student pharmacists, we hoped to improve continuity of care, medication adherence and communication to ensure collaborative care at discharge.

Methods: Student pharmacists were introduced to the process of receiving prior authorization needs of medications from insurance companies during the first week of their institutional or acute rotations at St. Luke's Rehabilitation Institute. They had access to patient profiles including insurance information, medication administration records, and plans for discharge. This service was provided to physicians and physician assistants for 8 weeks. At the conclusion of this pilot service, brief, confidential surveys were given to in-patient physicians, physician assistants and student pharmacists at St Luke's. These surveys consisted of 7 questions for physicians/ physicians assistants and 5 questions for student pharmacists to assess satisfaction with this prior authorization service. Paper surveys were distributed to all eligible respondents. Reminder emails to return surveys were sent to eligible respondents. Completed surveys were anonymously collected from respondents via pharmacy inboxes throughout the facility. Average satisfaction scores, times and responses were aggregated to provide a basis of improvement by the primary investigator and authors.

Results: Overall, response rate from physicians and physician assistants was 25 percent and 66 percent from student pharmacists. Physicians and physician assistants were satisfied with pilot service, rating it 5 on a 1-to-5 point scale. They spent, on average, 25 percent of their shift on prior authorizations before implementation of student-led prior authorization service. After initiation of pilot service, they spent on average 5 percent of their shift. Positive feedback included having more time with patients and increased collaboration on patient care with student pharmacists. Improvement feedback to this service showed that the student pharmacists should be able to obtain and complete prior authorization forms and be prepared to make medication suggestions upon meeting with patient's physician or physician assistant. Student pharmacists, on average, were moderately satisfied with piloting this prior authorization service (3.67 out of 5). Mean prior authorization need was 1 medication authorization per patient. Information review from insurance companies took on average 12.5 minutes to determine prior authorization need. Student pharmacists were satisfied with obtaining new information about the prior authorization process and providing continuity of care for patients. Suggested improvements included a desire for additional insurance resources and knowledge of which medications would be continued at discharge.

Conclusion: A student pharmacist-led prior authorization identification service increased healthcare collaboration in an in-patient rehabilitation setting. Identifying prior authorization needs prior to discharge would allow physicians and physician assistants to more efficiently plan discharge orders. The positive addition of student pharmacists as part of the healthcare team facilitated active learning by navigating insurance medication coverage. One limitation was using the same anonymous survey for physicians and physician assistants; therefore, not being able to identify the provider who benefited most from this service. Opportunities to expand this service include utilizing student pharmacists knowledge of medications to offer therapeutic alternatives to healthcare providers.

Poster Title: Public health impact of pharmacist intervention within an interprofessional clinic setting in Iquitos, Peru

Primary Author: Rachel Sullivan, Washington State University College of Pharmacy, Washington; **Email:** rlsullivan@wsu.edu

Additional Author (s):
Daiv Bhardwaj
Zhengsheng Peh
Alan Hoang
Catrina Schwartz

Purpose: From a public health perspective, counseling on lifestyle modifications is an integral part of patient care. As student pharmacists in an interprofessional healthcare team, we were in a position to provide valuable education and impact public health outcomes in Iquitos, Peru. The most common diagnoses in our clinic experiences were infections, chronic back pain, and malnutrition. Through literature review, all have been identified to be within the top 25 leading causes of global disability-adjusted life years (DALY). In providing education to patients with these diagnoses, pharmacists will be able to make a lasting impact on community, regional, and global health.

Methods: A total of 5 minor acute care clinics were held by an interprofessional team of pharmacy and nursing faculty and students within low income communities of Iquitos, Peru. The clinics were organized through an academic institution and arranged by a medically-driven non-profit community organization based locally in the host country. Patient specific information such as age, height, weight, blood pressure, and temperature were collected. Diagnoses, medications dispensed and the counseling provided were collected on intake forms for all clinics as part of a pharmacy APPE rotation. Patient demographic information, along with individual diagnoses, were entered into an excel spreadsheet and all patient information was de-identified. The data was analyzed for most common diagnoses, most dispensed medications, and the type of counseling provided. Our findings were then compared with similar data found upon literature review, focused on public health and global health trends.

Results: Data from a total of 284 patients were collected and analyzed. The mean patient age was 26.5 years, with females making up 62 percent of the patient population. Infections of various etiologies were the most common diagnoses, with a total of 42.6 percent. Student pharmacists were able to intervene in these patients and provide education on lifestyle modifications such as hygiene to prevent the spread of disease. Chronic back pain was the second highest percentage of diagnoses at 18.9 percent. Student pharmacists took part in counselling not only on proper use of analgesic medications, but also in demonstrating proper body mechanics. Third, malnutrition was diagnosed in 11.6 percent of patients and student pharmacists were able to provide education to this population about proper hydration and the importance of nutritious foods and a balanced diet. Of the 284 patients that were seen in clinic, 57 percent were seen for at least one of the above conditions, and each of these patients received extensive education regarding their diagnoses. Through education, we were able to increase health literacy and understanding in communities in Iquitos, which in turn can lead to a more lasting public health impact than simply dispensing medications.

Conclusion: Infections, chronic back pain, and malnutrition are identified as leading causes of global disability, and thus the importance of addressing these public health concerns is imperative. In an interprofessional clinic setting, pharmacists can aid in identifying these conditions and providing counseling on lifestyle modifications to prevent the spread of disease, strategies to alleviate chronic pain, and improve nutrition. This type of education can enhance the care of chronic conditions not only in Peruvian communities, but in the United States as well in an effort to improve global trends in disease.

Poster Title: Evaluating causes of hospital acquired Clostridium difficile infections and implementing a strategy to tailor appropriate antibiotic use

Primary Author: Galina Avdeyenko, Washington State University College of Pharmacy, Washington; **Email:** galina.avdeyenko@wsu.edu

Additional Author (s):
Jill Miller
Brent Albertson

Purpose: As a preventable negative outcome, hospital acquired Clostridium difficile infections have been an important quality measure at healthcare institutions. Thus, efforts have constantly been made to decrease Clostridium difficile infection rates among hospitalized patients in an effort to improve patient experience. Evaluating the causes behind hospital acquired Clostridium difficile associated diarrhea and implementing changes to address these causes have been key elements in reducing hospital acquired Clostridium difficile infection rates.

Methods: Retrospective chart review was performed for all hospital acquired Clostridium difficile cases encountered within eight months at Providence Sacred Heart Medical Center and Providence Holy Family Hospital. Several factors were found to be associated with Clostridium difficile infections including inappropriate antibiotic use, overuse of proton pump inhibitors and inappropriate testing for Clostridium difficile toxin. This project will further focus on tailoring antibiotic use. Also the 25 most recent Clostridium difficile cases were evaluated for the following aspects related to antibiotic use: need for antibiotics, selection of appropriate agent, and appropriate duration of therapy as established by treatment guidelines by the Infectious Diseases Society of America. This is a performance improvement project and is IRB exempt.

Results: 85 Clostridium difficile cases were analyzed. Trends noted were antibiotic use within the past three months, use of proton pump inhibitors and inappropriate testing. The most commonly used antibiotics at both institutions were cephalosporins, broad spectrum penicillins and fluoroquinolones. Among cephalosporins, first generation agents constituted 33 percent of total cephalosporin use at Holy Family Hospital and 46 percent of total use at Sacred Heart

Medical Center. Use of third generation cephalosporin agents was 41 percent and 30 percent at Holy Family and Sacred Heart respectively. Additionally, the 25 most recent cases were evaluated in depth in relation to antibiotic use. Of the 25 cases, 5 had inappropriate initiation of antibiotics, 1 had inappropriate choice of antimicrobial agent, 6 had inappropriate duration of therapy.

Conclusion: Clostridium difficile infections present an extreme burden for the healthcare system, and strategies to reduce infection rates are exceptionally valuable. A correlation between inappropriate antibiotic use and Clostridium difficile infections was observed in this analysis. Thus, it is crucial to ensure that antibiotic use is tailored in relation to appropriate initiation, choice of agent and duration of therapy. A crucial next step is evaluation of antibiotic use for disease states with specific therapy recommendations and provider education to hone in on proper antibiotic use. The hope is that a decrease in inappropriate antibiotic use will decrease Clostridium difficile infection rates.

Poster Title: Evaluation of the naloxone protocol: working to improve current opioid administration practices, patient monitoring, and documentation for patient safety.

Primary Author: Teri Lopez, Washington State University College of Pharmacy, Washington; **Email:** teri.lopez@wsu.edu

Additional Author (s):
Jill Miller
Brent Albertson

Purpose: Naloxone is a highly effective reversal agent for opiates; however, inappropriate use subjects patients to unnecessary side effects and inadequate pain control. The naloxone protocol at two acute care hospitals validates the need for naloxone administration in adults meeting one of two criteria: respiratory rate less than 8 breaths per minute and minimal response to verbal or tactile stimulation. This project aims to evaluate the current naloxone protocol and events that led up to the use of naloxone in each patient case to support the implementation of more stringent pain medication protocol use, standardized sedation assessments, documentation practices, and monitoring.

Methods: A medication use evaluation was completed for inpatient naloxone use at Providence Sacred Heart Medical Center and Holy Family Hospital. The project included patients 18 years and older who received at least one dose of naloxone as an inpatient from June 2016 to September 2016. Patients who received naloxone in the emergency department, operating room, or as a continuous infusion were excluded. An evaluation of the patient's charts was completed to determine the reasons for the naloxone administration and protocol adherence. Data collected included laboratory values, respiratory monitoring, opioid administration, patient controlled analgesia use, sleep apnea, concomitant benzodiazepine use, and as needed and range dose opioid use. Correlations between naloxone use and contributing factors will then assessed. This is a performance improvement project and is IRB exempt.

Results: Over the 11 week time period, 41 patients received naloxone as an inpatient. Of these 41 patients, 36 (88 percent) received naloxone appropriately according to the naloxone protocol, whereas 5 patients (12 percent) received it inappropriately. Interestingly, 12 patients

(29 percent) had no or minimal response to naloxone. If the Pasero Opioid-Induced Sedation Scale was utilized to help assess severity of sedation within the protocol, only 7 patients (17 percent) received naloxone appropriately. None of the patients had thorough documentation of the naloxone administration event. Respiratory monitoring was done using pulse oximetry for all 41 patients, whereas capnography, a better indicator for early hypoventilation, was not used at all. Patient controlled analgesia was used in 13 out of the 41 patients, and out of the 13 patients, only 7 patients (54 percent) followed the protocol for dose limitations. Risk for sleep apnea was assessed in only 16 patients (39 percent). Concomitant benzodiazepine use was found in 8 patients (20 percent) increasing their risk for respiratory depression and sedation. There were 30 patients (73 percent) who had as needed or range dose orders of pain medications, and only 15 patients (50 percent) followed the range dose opioid administration protocol appropriately.

Conclusion: More stringent pain medication protocol use shall be enforced while incorporating patient risk factors to help prevent the need for naloxone rescue. Also, the Pasero Opioid-Induced Sedation Scale should be incorporated into the current naloxone protocol to provide a less subjective assessment for patient sedation. Standardized documentation and monitoring while an opioid is used also needs to be established to provide appropriate validation for naloxone use. Future goals of this project are to assess the most common precipitating factors that lead to the use of naloxone and if certain comorbidities place patients at a higher risk for respiratory depression.

Poster Title: Role of Cholesterol Lowering Protein (PCSK9) in Rheumatoid Arthritis

Primary Author: Nikita Patel, Washington State University - College of Pharmacy, Washington;
Email: nikita.patel@wsu.edu

Additional Author (s):
Bhanupriya Madarampalli
Salah-uddin Ahmed

Purpose: Atherosclerosis is highly prevalent in patients with Rheumatoid Arthritis (RA) since inflammation can attack non-joint structures such as blood vessels, where arteries become hardened and blocked. Both diseases involve similar cells and pro-inflammatory cytokines in its pathogenesis. The purpose of our study was to evaluate the effects of PCSK9 (proprotein convertase subtilisin kexin 9), which lowers LDL cholesterol, on inflammatory cytokines and signaling pathways in cytokine-stimulated Rheumatoid Arthritis synovial fibroblast cells. If PCSK9 does play a role in inflammation, PCSK9 inhibitors could potentially be used for Rheumatoid Arthritis patients with Atherosclerosis.

Methods: RA synovial fibroblast cells from different patients were obtained from NDRI (National Disease Research Interchange) and CHTN (Co-operative Human Tissue Network), grown in media until they were confluent, and seeded onto a 6-well plate for treatment. Then the cells were starved in serum free media for 16-18 hours. The next day, fresh serum free media was added and each 6 well plate was pretreated with different PCSK9 concentrations for 30 minutes. The cells were then stimulated with the inflammatory cytokine IL-1β for 24 hours for ELISA (enzyme-linked Immunosorbent assay) or 30 minutes for Western Blotting. For the ELISA process, IL-6 and IL-8 (inflammatory mediators) levels were measured in culture supernatants in response to varying PCSK9 treatments using ELISA kits (from R&D Systems®). For Western immunoblotting, total protein was estimated using BCA (bicinchoninic acid) method. In this process, 25 μg of total protein was loaded onto polyacrylamide gels and transferred onto PVDF (polyvinylidene difluoride) membranes by wet blotting. The membranes were probed for primary antibodies p-P38 and p-JNK (Cell Signaling Technologies®), which are part of the MAP kinase signaling pathway, in 1:1000 concentration overnight at 4°C and

subsequently developed using the substrate. Membranes were stripped and re-probed for β-actin (from Santa Cruz Biotechnology Inc.®) as a loading control.

Results: PCSK9 was discovered to reduce the expression levels of both pro-inflammatory cytokines IL-6 and IL-8 in Rheumatoid Arthritis synovial fibroblasts, with higher concentrations of PCSK9 reducing these pro-inflammatory cytokines the most. PCSK9 was also found to partly activate the MAP kinase signaling pathway in Rheumatoid Arthritis synovial fibroblasts through analyzing the effects of PCSK9 on the primary antibodies p-P38 and p-pJNK.

Conclusion: In Rheumatoid Arthritis synovial fibroblasts, PCSK9, in a dose-dependent manner, reduced the expression levels of pro-inflammatory cytokines and had a partial effect on reducing signaling pathways. However, further studies should be performed to determine the exact underlying relationship and mechanism. To validate our preliminary data, future studies in animal models of Rheumatoid Arthritis will be performed. However, our data has offered initial results that suggest the effect PCSK9 inhibitors have on inflammation in patients with Rheumatoid Arthritis, allowing the potential for PSCK9 inhibitors to be used for Rheumatoid Arthritis patients with Atherosclerosis.

Poster Title: Non-Cardiac Drug Induced QT/QTc Prolongation: A Retrospective Chart Review

Primary Author: Obi Okafor, Howard University College of Pharmacy, Washington, District of Columbia; **Email:** obi.okafor@bison.howard.edu

Additional Author (s):
Maritsa Serlemitsos-Day
La'Marcus Wingate

Purpose: Assessment of the effect of non-cardiac medications has not been well characterized for non-specific conduction disorders, specifically QT Prolongation in a predominately urban, African American population. Prolonged QTc (QT interval corrected for heart rate) is clinically associated with the dangerous ventricular arrhythmia, Torsades de Pointes (TdP) which can lead to sudden cardiac arrest. Currently, data on the prevalence of QTc prolongation in these minorities is limited. This study evaluated the effect of non-cardiac drugs on the QT Interval in a large public university associated teaching hospital serving an urban, predominately minority population.

Methods: Electronic medical records were utilized to conduct a retrospective chart analysis for patients admitted to Howard University Hospital (HUH) from January 2013 to December 2015. Patients were selected for inclusion if they had an electrocardiogram (EKG) during their inpatient stay, and were diagnosed with a non-specific conduction disorder (ICD-9 code 794.31). Exclusion criteria included age < 18, prior history of NYHA Stage II/IV heart failure, pregnancy and no EKG upon admission. Data extracted were patient demographics, laboratory data, comorbidities, and administered medications. PR, QT and QRS intervals were measured from the EKG and the corrected QT (QTc) interval was calculated using Bazett's formula considering < 450 ms as normal and adjusting for heart rate. The thresholds used to define an elevated QTc interval were > 450 ms and 500 ms. Patients were categorized into three groups on the basis of how many non-cardiac QTc prolonging drugs they were taking: either zero, one or multiple non-cardiac QTc prolonging drugs. The groups were compared at baseline using chi-square statistics for categorical variables and ANOVA for continuous variables. Bivariate logistic regression was utilized to determine which of the independent variables were associated with an elevated QTc interval and multivariate logistic regression models were developed to

ascertain whether utilization of non-cardiac QTc prolonging drugs was independently associated with a prolonged QTc interval after adjusting for confounders.

Results: Altogether, 121 patients met inclusion criteria, and 71 (59%) were taking at least one non-cardiac QTc prolonging medication. Patients taking multiple non-cardiac QTc prolonging medications had a higher mean QTc interval (503+64.6 ms) than those taking only one of these medications (484.2+42.0 ms) or none at all (467.4+53.5 ms). In bivariate logistic regression analysis, factors associated with a QTc interval > 450ms included multiple non-cardiac QTc prolonging medications (OR=4.36, p=0.02) and presence of an endocrine disorder (OR=3.28, p=0.02). Factors associated with a QTc interval > 500 ms in bivariate analysis included multiple non-cardiac QTc prolonging medications (OR=2.66, p=0.04) and hypokalemia (OR=2.73, p=0.04). After adjusting for confounders using multivariate logistic regression, the odds of a QTc interval > 450 ms were 4 times higher in patients taking multiple non-cardiac QTc prolonging medications (p=0.04) when compared to patients taking no non-cardiac QTc prolonging medications. Although the likelihood of a QTc interval > 500 ms was higher when taking multiple QTc prolonging medications (OR=2.77, p=0.06), the association was no longer statistically significant after adjusting for confounders in a multivariate logistic regression. The most common class of offenders was antipsychotics medications, with Seroquel (N=12), Advair (N=11) and Abilify (N=6) being the most frequent.

Conclusion: In this underserved population, over half of the patients studied received at least one medication known to prolong to QT interval, and many of these patients had elevated QTc intervals. The patients with QTc prolongation have higher odds of developing adverse outcomes. While none of the patients in this study presented with TdP, further studies are warranted to determine the clinical implications of the alarming presence of elevated QTc intervals, including surveillance and characterization of the degree of TdP.

Poster Title: School of pharmacy faculty members' perceptions of students' knowledge of medical terminology

Primary Author: Lyndie Gore, University of Wyoming, Wyoming; **Email:** lyndp@uwyo.edu

Additional Author (s):
Michelle Hilaire
Kristen Bene
Drew McMillan

Purpose: Medical Terminology is not a required standalone course within the University of Wyoming School of Pharmacy (UW SOP) curriculum. With the implementation of inter-professional education experiences, mandated by the 2016 ACPE standards, common medical terminology language is needed for communication among health professional students. This study was designed to gauge school of pharmacy faculty members' perceptions of current student's knowledge in medical terminology. Areas of focused questions included: are students weak in medical terminology; is medical terminology offered in coursework throughout the SOP; and should this be a mandated course.

Methods: This research was given exempt status through the institutional review board. A survey was conducted and all faculty members in the University of Wyoming School of Pharmacy were given a survey at the beginning of the 2015 Fall Academic Year. Faculty used Likert-type scales to rate their responses regarding their perceptions of student ability levels, preparation, and readiness to utilize medical terminology while in pharmacy school. We also collected qualitative data about faculty members' personal utilization of medical terminology in their courses.

Results: Eighty-six percent of the faculty completed the survey. Fifty-eight percent of the faculty believed that medical terminology should be a required course in Pharmacy School and sixty-four percent currently included medical terminology into lectures. Only thirty-eight percent of faculty agreed or strongly agreed that students were prepared to use medical terminology on rotations.

Conclusion: The results have been shared with the School of Pharmacy curriculum committee. In the short term, faculty will look for additional opportunities to implement medical terminology into existing courses. Courses such as Physical Assessment, Pharmacy Practice Lab, and Pathophysiology were identified as key places for enhancing the curriculum with medical terminology. Future implications include surveying fourth year pharmacy students both pre- and post-rotations to gauge their confidence in using medical terminology and the impact of this on inter-professional interactions.

Poster Title: Pharmacist involvement in Accountable Care Units on general medicine floors at a community hospital

Primary Author: Jessica Papke, University of Wyoming, Wyoming; **Email:** jpapke93@gmail.com

Additional Author (s):
Allison Mann

Purpose: In 2001, the Institute of Health came out with a report titled Crossing the Quality Chasm: A New Health System for the 21st Century. The report stated that, "the delivery of care often is overly complex and uncoordinated, requiring steps and patient 'handoffs' that slow down care and decrease, rather that improve safety." A community hospital attempted to coordinate and target patient care through the creation of Accountable Care Units (ACU) to care for patients admitted to the internal medicine service.

Methods: An Accountable Care Unit (ACU) is a geographic care area responsible and accountable for the clinical, service, and cost outcomes it produces. The 4 features of a ACU are 1) unit based teams 2) patient centered workflow 3) unit level performance data and 4) unit management partners. The physicians and nurses are geographically on the same floor and only follow patient on that floor. There is also a staff pharmacist and case manager that follow only patients on that floor. By sharing space, time, and process, teamwork is an inevitable outcome. To increase patient centered workflow, the ACU implemented Structured-Interdisciplinary-Bedside-Rounds (SIBR). These daily rounds standardize communication between the team and include the patient in the team's cross checks each to improve the quality and safety of care. By creating unit based data, the ACU can identify areas of strength and areas that need improvement. Having duel leadership between a Medical Director and Nurse ensures consistency of the ACU's policy through both disciplines and making sure the staff feel connected to the goals of the unit.

Results: Since the implementation of the ACU on the ward, there have been a decrease in 30 day readmissions, decreased medical costs, and decreased length of stay. The doctors were also able to interact with the patient more. They did not have to go all the way across the hospital to find their patients because of the geographical set up of the ACU. During SIBR, we were able to

make an interdisciplinary patient care plan centered around the patient's needs. By including the patient, we are making them more responsible for their personal health care. In addition, implementing SIBR rounds made sure that the entire medical team was on the same page about the plan for the day.

Conclusion: There are multiple problems in the United States health care system that lead to patient safety issues including the structure of the system. By restructuring our hospital wards, we can enhance communication between providers and build engagement to improve the quality of care a patient receives. Comradery is built between the team because they are constantly around each other, caring for the same patients. Being an active part of the delivery of care makes providers more invested in the care of their patient's, as well as their patient's final outcomes, thus improving patient safety.

Submission Type: Evaluative Study

Session-Board Number: 2-436

Poster Title: Assessment of testosterone replacement therapy monitoring within the Cheyenne veterans affairs medical center

Primary Author: Heather Dickson, University of Wyoming School of Pharmacy, Wyoming;
Email: hdickson@uwyo.edu

Additional Author (s):
Amanda Thompson

Purpose: Testosterone replacement therapy is a restricted treatment prescribed in the veteran's affairs setting that requires monitoring to assess safety and efficacy of its use. The purpose of this medication utilization evaluation (MUE) is to determine if testosterone is monitored appropriately in the VA population of Cheyenne, WY. Per VA criteria for use, morning testosterone levels between 7:30 and 10:00am, hematocrit and hemoglobin, prostate specific antigen, liver function tests and lipid profiles should be monitored annually. A hematocrit level greater than 54% warrants a discontinuation of therapy due to increased risk of venous thromboembolism.

Methods: This MUE initially reviewed 154 patients at the Cheyenne VA medical center that were currently taking testosterone. This data was obtained using a database through the computerized patient record system (CPRS). Patients were identified that had an active prescription for testosterone replacement therapy within the 15 month period of March 2015-June 2016. This medication utilization evaluation did not assess whether or not these patients met inclusion or exclusion criteria when they were originally initiated on testosterone. Once the patient list was established, the date of the initial consult was used to determine if the patient had a renewal consult within 15 months from that consult. If the patient met these two previous criteria, labs were reviewed within that same 15 months to determine if the patient had appropriate lab monitoring. Labs included: testosterone, hematocrit and hemoglobin, PSA, liver function tests, and a lipid profile. If the patient did not have any one of these labs monitored within the 15 month period, it was considered as inappropriate monitoring. The timing of testosterone levels was also evaluated. If levels were drawn at 10:00am or earlier, it was considered an appropriate sample, and levels drawn at 10:01am and later were considered inappropriate.

Results: Of the 154 patients that were currently taking testosterone replacement therapy, 34 patients were excluded for this report because they had not been on testosterone therapy for 15 months. Out of the 119 eligible patients, 95 patients had a renewal ordered within 15 months of initiating treatment or within 15 months of other renewals. A majority of the patients had a testosterone level (76.5 percent), hematocrit/hemoglobin level (88.2 percent), CBC panel (85.7 percent), PSA levels (75.6 percent), AST/ALT levels (80.6 percent), and a lipid panel (81.5 percent) within the 15 month period. A total of 15.1 percent of patients had a hematocrit above 54 percent during treatment and 65.5 percent of patients had testosterone levels drawn after 10:00am. During March 2015-June 2016, providers at the Cheyenne VA healthcare system completed approximately 80 percent appropriate renewals for patients taking testosterone replacement therapy. Patient's labs were being appropriately monitored every 15 months and a majority of patients did not have a hematocrit above 54 percent. However, 65.5 percent of testosterone levels were drawn after 10:00am.

Conclusion: The monitoring of testosterone replacement therapy is not being completed appropriately at the Cheyenne VA medical center. Areas of improvement for the future include: provider education on the appropriate timing of drawing testosterone levels, obtaining all necessary follow-up labs and assessment, and follow-up of those patients still taking testosterone replacement therapy when HCT levels are greater than 54 percent.

Submission Type: Evaluative Study

Session-Board Number: 2-437

Poster Title: Effect of twice-daily vs. once-daily dosing on hemoglobin A1c with long-acting basal insulin glargine U100

Primary Author: Linzi Barton, University of Wyoming School of Pharmacy, Wyoming; **Email:** linzb417@gmail.com

Additional Author (s):
Thanh-Nga Nguyen

Purpose: Insulin glargine U100 is a long-acting basal insulin approved by the Unites States Food and Drug Administration (FDA) to be administered once daily for the treatment of Diabetes Mellitus. The estimated duration of action is between 10 to greater than 24 hours. As such, it is thought to be more effective at lowering hemoglobin A1c (A1c) when giving this insulin twice daily compared to once daily in certain cases. Literatures on glargine U100 twice daily and HgA1c reduction are lacking. This retrospective chart review aims at assessing whether or not twice daily dosing has an advantage over once daily dosing.

Methods: This cross-sectional analysis is pending approval from the institutional review board. Patients of the University of Wyoming Family Medicine clinic in Cheyenne, WY who had a prescription for insulin glargine U100 (Lantus) on their profile between June 1, 2015 and May 31, 2016 were identified. A chart review was then performed to collect total daily insulin dose, most recent A1c value, dosing frequency, type of diabetes mellitus, the date started on their current dose of insulin, and the date of their last A1c. The average A1c was then compared between those taking insulin glargine U100 daily and those taking it twice daily using an unpaired Student's t-test.

Results: Twenty-four patients were identified with a prescription for insulin glargine U100 on their profile and an A1c value that had been measured after their insulin dose or schedule had changed. Of these, five were taking insulin glargine U100 on a twice-daily schedule and nineteen were taking it on a once-daily schedule. The average A1c in the group that administered insulin glargine twice daily was 9.14%, and the average when administered once daily was 8.7%. This data was then analyzed, and our results showed that using twice-daily

versus once-daily yielded no significant difference on the A1c value (95% CI: -1.05 to 1.93, p=0.53).

Conclusion: Our results showed that there is no statistically significant difference between using insulin glargine U100 twice daily versus once daily in lowering the A1c level. Given the small sample size and many potentially confounding factors, such as the initial control that subjects had when each regimen was initiated, the time since the regimens were initiated, and potentially variable adherence to the regimen among the subjects, a Type II error should be ruled out with further studies.

Submission Category: Oncology

Submission Type: Descriptive Report

Session-Board Number: 2-438

Poster Title: Accuracy of documentation and monitoring of oral chemotherapy in a small community cancer center

Primary Author: Samantha Holmes, University of Wyoming School of Pharmacy, Wyoming; **Email:** sholmes3@uwyo.edu

Additional Author (s):
Kelsea Zukauckas
Cara Harshberger

Purpose: Advancements in oncologic research has led to the approval of new oral chemotherapy agents including endocrine therapy and cytotoxic agents. These self-administered agents provide patients with a convenient option with perceived benefits of less clinic visits and less complications. However, oral chemotherapy is only effective when patients adhere to the prescribed administration schedule. The potential for drug-drug interactions and unwanted toxicity can lead to non-adherent patients. While chemotherapy education can help identify potential problems in the beginning, continued monitoring and assessing patient adherence when patients are seen in clinic can lead to better efficacy, patient outcomes and overall survival.

Methods: Retrospective chart reviews were completed and de-identified prior to analysis by the primary author. A two-month time period from May to June of 2016 of a small community oncology clinic schedule was reviewed. All patients identified to be on oral chemotherapy were evaluated for this study. Adherence documentation, chemotherapy education documentation, monitoring documentation per package insert from manufacturers, documentation within the electronic medication record (EMR) on the medication home list, and documentation of drug interactions were reviewed and assessed for each individual patient that was identified.

Results: In the two-month time frame, there were 48 patients identified to be on oral chemotherapy or endocrine therapy, of these patients 20 were on oral chemotherapy. Adherence with oral chemotherapy or endocrine therapy was not documented within provider notes specifically in any of these patients. Chemotherapy education was not always documented within the EMR and monitoring parameters were not discussed within provider

notes in the EMR . Over half of the patients did not have these medications added to their home medication lists that were accessible by other departments utilizing the EMR. Drug-drug interactions were not documented in most cases and upon review many patients had drug interactions that were a category D. Most documentation within the medication list was incorrect in the EMR.

Conclusion: This study illustrates the difficulty encountered with new oral chemotherapy agents especially with regard to documentation and assessment of adherence and toxicity. Currently, there is no mechanism within the EMR to trigger providers to ask specific questions or to document on oral chemotherapy. Electronic medical record support will be developed to assist with the documentation of therapy within this population of patients. This study also supports the need for a clinical oncology pharmacist to assist with the management, monitoring and documentation of appropriate therapy in oral chemotherapy and endocrine therapy patients.

Poster Title: Retrospective data analysis on the benefits of having a standing order for emergency contraceptives and the proper medication administration

Primary Author: Jeannette Bouchard, Regis University, Colorado; **Email:** jbouchard001@regis.edu

Additional Author (s):
Aimee Dietle
Marisa Campanale
Lori Lewicki

Purpose: In the United States there are only 9 states that allow pharmacists to dispense emergency contraception (EC) under a collaborative practice agreement or a state-wide standing order. In Massachusetts two EC products are available through standing order, levonorgestrel and ulipristal acetate. Patients often use over-the-counter (OTC) levonorgestrel due to ease of access, however prescription only ulipristal acetate may be more clinically appropriate for certain patients. The purpose of this study was to investigate the benefits of an EC standing order in a federally qualified health center (FQHC) pharmacy.

Methods: This was a retrospective review of pharmacy data approved by an institutional review board. Patient records were eligible for inclusion in this study if the patient received an EC product via standing order between August 2015 and August 2016. Patient records were excluded if the intake form was missing information/not complete. The pharmacy's emergency contraception intake form was analyzed retrospectively. The primary objective of the study was to investigate how many patients who received EC were indicated to receive ulipristal acetate. Secondary objectives for the study were to determine the reason why a patient was indicated for one product over the other, evaluate the costs for patients who received EC through standing order and assess whether a referral was needed for patients. Pertinent data included: the date the patient received the EC, the reason for EC, number of days since last intercourse, date of last menstrual cycle, height, weight and body mass index of the patient, any current medications the patient is taking, whether or not anti-nausea medication (meclizine) was recommended, whether ulipristal acetate or levonorgestrel was dispensed, and whether there was a referral and decision made.

Results: Thirty EC intake forms were reviewed. Two were excluded due to incompleteness of the intake form. Out of the 28 records meeting inclusion/exclusion criteria, 5 patients received levonorgestrel and 23 received ulipristal acetate. Two of the five levonorgestrel recipients had a body mass index that would categorize them for ulipristal acetate; however, ulipristal acetate was on backorder at the time. All 23 patients that received ulipristal acetate had patient characteristics that would make levonorgestrel a non-preferred agent. Two patients received ulipristal acetate due to seeking EC more than 72 hours since last intercourse. Twenty-one patients received ulipristal acetate due to a BMI over 25kg/m2. In studies, levonorgestrel has shown to have lower efficacy for overweight patients compared to ulipristal acetate. One patient was counseled on the benefit of an intrauterine device instead of oral EC due to a body mass index of 38kg/m2. The patient declined and chose to use ulipristal acetate instead. All patients received instructions for use of each EC product and standardized counseling from a pharmacist . Six patients accepted the suggestion to be referred to a provider. All patients who received EC from the clinic were able to receive EC with $0 co pay.

Conclusion: Prescription only ulipristal acetate was indicated in 77% of patients that would not have had access to it without a standing order. Patients receiving EC via a standing order were able receive information on EC and obtain referrals to providers. These benefits are unlikely to occur when purchasing EC over the counter. Additionally, OTC EC typically costs patients between 40 and 50 dollars. Patients in the study received the medication at no out-of-pocket cost through insurance. Utilizing a standing order greatly benefited patients seeking EC and should be expanded throughout the country.

Poster Title: Real-world diabetes outcomes after a Medicaid formulary change in long-acting insulin analogue from insulin glargine to insulin detemir

Primary Author: Paul Cornelison, Regis University School of Pharmacy, Colorado; **Email:** pcornelison@regis.edu

Additional Author (s):
Charlotte Ricchetti

Purpose: Long-acting insulin analogues have varying pharmacokinetic profiles that may influence their relative effect on hemoglobin A1c (HbA1c), hypoglycemic episodes, weight, and total daily insulin dose in patients with diabetes mellitus. Existing studies on the effects of switching basal insulin formulations have had conflicting results and often examine a population who is dissatisfied with or not controlled on the current insulin. The purpose of this study is to retrospectively examine the clinical efficacy and safety outcomes of a formulary-mandated switch from insulin glargine to insulin detemir in patients receiving their diabetes care at a Federally Qualified Health Center (FQHC).

Methods: The institutional review board for Regis University approved this retrospective chart review. Patients who were 18 years and older with type 1 or type 2 diabetes were included if they received care at Clinica Family Health (CFH), had Colorado Medicaid as their primary insurance, had been on insulin glargine for at least 6 months, and had their insulin switched from insulin glargine to insulin detemir between April 1, 2014 and April 1, 2015 as a result of the mandated formulary conversion. Patients who left care at CFH less than 6 months after switching basal insulin, had a diagnosis of gestational diabetes, lacked a HbA1c at baseline or 6-months (plus or minus 30 days) post-switch were excluded. The primary outcome was change in HbA1c at 6 months. It was estimated that 88 patient charts would need to be reviewed to detect a change of 0.54 percent in HbA1c, using a two-sided alpha of 0.05 and 95 percent power. Secondary outcomes included HbA1c at 1 year, total daily basal insulin dose, use of bolus insulin, total daily bolus insulin dose, weight, twice daily basal insulin regimen, use of oral antidiabetic agents (OADs), number of patients converted back to insulin glargine, diabetes-related hospitalizations, and severe hypoglycemia. All outcomes were assessed at 6 months and 1 year (OADs only at 6 months).

Results: A report has been generated that identifies all Medicaid patients who were receiving care at CFH and who were on insulin glargine at the time of the shift in preferred insulin. This report has identified 235 potential candidates for inclusion. Data collection is ongoing, and results are anticipated to be complete in December 2016.

Conclusion: This study fills a gap in the existing literature on the effects of switching from insulin glargine to insulin detemir. It describes the real-world clinical effects of a mandated (rather than elective) change in basal insulin in a medically underserved population.

Poster Title: Implementation of education with ongoing feedback for the appropriate treatment and diagnosis of urinary tract infections: Antimicrobial stewardship collaborative with Colorado Hospital Association

Primary Author: Audra Wilson, Regis University School of Pharmacy, Colorado; **Email:** awilson007@regis.edu

Additional Author (s):
Kylie Mueller

Purpose: Urinary tract infections (UTIs) continue to be one of the most common indications for antibiotics among hospitalized patients, yet the diagnosis and treatment varies among providers. Increasing resistance of urinary pathogens, increased risk of collateral damage, and the inappropriate treatment of asymptomatic bacteriuria has led to the creation of antimicrobial stewardship programs within Colorado institutions. The goals of this collaborative include the following: decrease the rate of Clostridium difficile infection (CDI), reduce fluoroquinolone use, limit duration of treatment, reduce readmission rates for UTIs, and improve the accurate diagnosis of UTIs according to the Infectious Diseases Society of America (IDSA) guidelines.

Methods: This collaborative encompasses both a retrospective chart review for baseline data collection and an ongoing interventional phase in conjunction with the Colorado Hospital Association. Baseline data was collected for 80 randomly selected patients with a UTI diagnosis during the year 2014 using the electronic medical record system. The interventional phase includes daily prospective review with feedback and education from Infectious Diseases (ID) specialists (e.g. ID pharmacist, ID attending physician), bimonthly education sessions to hospitalists and Emergency Department providers, creation of flowcharts for the diagnosis and treatment of UTIs, and daily reports to identify patients on fluoroquinolones and treatment of asymptomatic bacteriuria. Quarterly review of 20 randomly selected patients with UTI diagnoses is completed for post-implementation data collection.

Results: Baseline data collection revealed that 48 percent of patients met IDSA guideline definition of UTI. Of these, only 69 percent of patients had localizing urinary symptoms present and 30 percent of patients did not have a urine culture performed. At baseline, 56 percent of patients were treated with fluoroquinolones and the median total duration of therapy was eight days. There were 5 percent of patients readmitted within 30 days for a UTI. Preliminary post-implementation phase data reveals an average of 43 percent of patients meeting IDSA guideline definition of UTI. Fluoroquinolone prescribing has decreased to an average of 43 percent during the post-implementation phase. Further, the median total duration of therapy during this period is eight days. There has been a decrease in patients readmitted within 30 days for UTI to 2 percent in the post-implementation phase. Quarterly results are ongoing and continue to be collected.

Conclusion: Based on preliminary post-implementation data, fluoroquinolone prescribing and readmissions for UTIs have decreased. The main area for continued improvement is the appropriate diagnosis of an UTI and decreased treatment of asymptomatic bacteriuria. Continued efforts at educating providers with daily reminders and the creation of flowcharts to help streamline the proper approach to diagnosing and treating UTIs will continue to improve antimicrobial stewardship practices in this area.

Submission Type: Evaluative Study

Session-Board Number: 3-004

Poster Title: Effect of the implementation of a pharmacist-directed, nurse-run antiarrhythmic drug monitoring program

Primary Author: Nyles Fowler, Regis University School of Pharmacy, Colorado; **Email:** nfowler@regis.edu

Additional Author (s):
Paul Shaw
Olivia Rapacchietta
Kobi Nguyen

Purpose: Antiarrhythmic medications carry risk of toxicity and adverse drug events, yet safety monitoring guidelines are not well-established for many of them. In collaboration with Kaiser Permanente Department of Cardiology, including electrophysiologists and nurses, clinical pharmacy specialists developed monitoring guidelines for these medications. Additionally, a multidisciplinary antiarrhythmic drug monitoring program was implemented; it utilized a refill protocol which made refills contingent upon compliance with monitoring. The purpose of this study was to determine the impact of the monitoring program on compliance with the recommended safety monitoring parameters.

Methods: This institutional review board-approved, retrospective cohort study evaluated patients who received antiarrhythmic drug therapy before (control group) and after (intervention group) the implementation of an antiarrhythmic monitoring program which occurred on 10/1/2011. Patients were included if they were aged 18 years and older and had filled a prescription for an antiarrhythmic drug prescribed by a cardiologist during the study period. Monitoring in the control group consisted of standard care by the managing cardiologist and encompassed the study period 7/1/2011 to 10/1/2011. Monitoring in the intervention group was done through a pharmacist-directed, nurse-run prescription refill protocol which prompted patients to complete recommended safety monitoring prior to receiving antiarrhythmic drug refills with a study period of 4/1/2016 to 7/1/2016. The drugs included were disopyramide, dofetilide, dronedarone, flecainide, mexiletine, procainamide, propafenone, quinidine, and sotalol. Amiodarone was excluded because it was monitored by a separate, pre-existing monitoring service. Specific monitoring parameters, including labs and

electrocardiograms, and their recommended frequency varied by drug. Chart review of the electronic medical record was performed to determine whether each monitoring test was complete or incomplete. The primary outcome measure was the total percent compliance with recommended safety monitoring parameters for all antiarrhythmic drugs in each group. Secondary outcomes included the percent compliance for individual antiarrhythmic drugs. Statistical comparison for differences between groups was performed using chi-square test.

Results: A total of 349 patients comprising 807 recommended monitoring tests were identified as the control group. The intervention group consisted of 531 patients comprising 1158 recommended monitoring tests. For the primary outcome, the intervention group completed 971 out of 1158 (83.9 percent) recommended monitoring tests versus 586 out of 807 (72.6 percent) in the control group representing a statistically significant difference (p less than 0.0001). Within the secondary outcomes, compliance with monitoring increased significantly for dofetilide (80.3 vs 57.7 percent) and sotalol (83.1 vs 54.9 percent).

Conclusion: Implementation of a pharmacist-directed, nurse-run antiarrhythmic drug monitoring program significantly improved compliance with overall safety monitoring. The majority of this improvement was driven by significantly increased compliance with dofetilide and sotalol monitoring. The impact of improved safety monitoring on clinical outcomes was beyond the scope of this study and is yet to be determined.

Poster Title: Characterization of the T cell response induced by an experimentally isolated antigen to evaluate its potential role in the immune-mediated pathology of Multiple Sclerosis

Primary Author: Derrick Waller, Regis University School of Pharmacy, Colorado; **Email:** dwaller@regis.edu

Additional Author (s):
Kelly Stone
Brandon Kondo
Samantha Kusher
Stephanie James

Purpose: Multiple Sclerosis (MS) is a demyelinating disease affecting approximately 2.3 million people worldwide. While suspected to be an autoimmune disease, the exact cause of MS remains unknown. Current treatment options are only moderately effective, due in large part to this lack of pathophysiological understanding. Immunoglobulins are found to be elevated in the cerebrospinal fluid (CSF) of MS patients, but not healthy controls, suggesting the involvement of B cells in MS patient CSF. This study investigated the ability of an antigen, isolated from MS CSF antibodies, to initiate T cell activation in vitro to evaluate its potential role in MS pathology.

Methods: The institutional review board approved this case-control study. Peripheral blood mononuclear cells (PBMCs) were obtained from the Rocky Mountain MS BioBank as well as from healthy volunteers to serve as controls. Samples were coded to blind the researchers throughout conduction of T cell specificity assays using a mixed lymphocyte assay and analysis via flow cytometry. Both MS (n = 16) and control (n = 12) PBMC samples were incubated for 6 hours at 37 degrees Celsius, 5.5 percent CO_2 in the presence of a positive control, negative control, or the experimental antigen to allow for T cell activation and proliferation. The samples were then stained with antibodies against CD3, CD4, CD8, CD45RA, CD45RO, CD40, Th17, IFN-gamma, and Ki-67 to allow for discernment by flow cytometry. IFN-gamma served as a marker for T cell activation, Ki-67 as a marker for T cell proliferation, and the other stained proteins permitted evaluation of specific T cell subpopulations (e.g. memory vs. naïve, helper vs. cytotoxic, etc.). The samples were unblinded after flow cytometry analysis and the data

evaluated, comparing MS and control groups using a Student's t-test to determine significance of any observed differences.

Results: Interestingly, there was a significant increase in average T cell activation, as measured by IFN-gamma production, for both CD4+ and CD8+ T cells in the control samples compared to the MS patient samples (CD4+: 6.63 percent vs. 1.64 percent; CD8+: 6.4 percent vs. 0.55 percent; P less than or equal to 0.05). Control samples also demonstrated a higher level of T cell proliferation, as measured by Ki-67, versus the MS samples (CD4+: 13.63 percent vs. 2.58 percent; CD8+: 9.85 percent vs. 1.79 percent; P less than or equal to 0.05). However, this did not correlate with an increase in CD40 expression, indicative of antigen-presenting cells, in the control samples (24.76 percent controls vs. 47.83 percent MS; P equals 0.13). When comparing memory vs. naïve T cell responses, the MS samples showed a stronger naïve response (CD4+: 65.27 percent vs. 44.71 percent, P equals 0.07; CD8+: 82.47 percent vs. 67.01 percent, P equals 0.04) and a similar memory response (CD4+: 36.52 percent vs. 38.02 percent, P equals 0.9; CD8+: 9.76 percent vs. 14.75 percent, P equals 0.38) compared to the control samples.

Conclusion: Theoretically, MS patient PBMCs should recognize an antigen targeted by antibodies in the CSF of MS patients while the PBMCs from healthy volunteers should not. Subsequently, a stronger memory T cell response in the MS patient samples would be expected; however, that was not observed in this study. The explanation for these results is unclear. The antigen might be presented differently in vitro vs. in vivo. The B/T cell interactions of interest could be CSF specific and absent in the periphery. Validation and elucidation of these results will require further investigation of a larger number of samples.

Poster Title: Synthesis and biological evaluation of anti-tumor agents inspired by marine sponges

Primary Author: Brayden Hamill, University of Colorado Anschutz Medical Campus

Skaggs School of Pharmacy and Pharmaceutical Sciences, Colorado; **Email:** brayden.hamill@ucdenver.edu

Additional Author (s):
Ahsun Babalmorad
Adedoyin Abraham
Daniel LaBarbera

Purpose: The medicinal chemistry of benzimidazole based alkaloids with extended amidine functionality were investigated for their anti-tumor potential. Preliminary data show these agents target the N-terminal ATP binding sites of Topoisomerase two alpha, resulting in potent anti-tumor activity. Various derivatives were synthesized and tested in order to further investigate their bioactivity, anti-tumor effects and their ability to inhibit or reverse epithelial-mesenchymal transition (EMT) in metastatic SW620 colon cancer cell lines.

Methods: The synthesis of various extended amidine benzimidazoles was performed starting with commercially available starting material. 4-methyl-2-nitroaniline was acetylated to form N-(4-methyl-2-nitrophenyl) acetamide with acetic anhydride and sulfuric acid. Methylation of N-(4-methyl-2-nitrophenyl) acetamide was performed using dimethyl sulfate in potassium hydroxide solution to form N-methyl-N-(4-methyl-2-nitrophenyl) acetamide. Reduction of the dinitro group of N-methyl-N-(4-methyl-2-nitrophenyl) acetamide generates the N-(2-amino-4-methylphenyl)-N-methylacetamide followed by subsequent Phillips condensation in refluxing sulfuric acid to form the 1,2,5-trimethyl-1H-benzimidazole. 4,6-dinitro-1,2,5-trimethyl-1H-benzimidazole was generated via dinitration of 1,2,5-trimethyl-1H-benzimidazole with sulfuric and nitric acid. Catalytic reduction of 4,6-dinitro-1,2,5-trimethyl-1H-benzimidazole was performed using palladium on carbon in methanol to generate the 4,6-diamino-1,2,5-trimethyl-1H-benzimidazole. Fremy's oxidation of 4,6-diamino-1,2,5-trimethyl-1H-benzimidazole generated the phosphate salt of 6-amino-4-imino-1,2,5-trimethyl-1H-benzimidazole-7-one, which was then transaminated using primary amines in methanol at 30-40 degrees centigrade

to form various extended amidine benzimidazole alkaloids (BH-12-198, BH-12-203, BH-12-205, BH-12-206, BH-12-207, BH-12-209, BH-12-210, BH-12-212, BH-12-213, BH-12-214). Compounds were purified by reverse phase chromatography and biological analysis was assessed using the sulforhodamine B (SRB) cytotoxicity assay, measured effects on EMT via reporter and Western blot analysis, and a modified Boyden invasion assay were used to evaluate the anti-tumor activity of these molecules.

Results: The anti-tumor potential of the various extended amidine benzimidazoles was investigated in the SW620 colon cancer cell line through inhibition concentration fifty-percent (IC) cytotoxicity determination. The inhibition concentration fifty-percent per agent were as follows: BH-12-198 (0.910 micromolar), BH-12-203 (0.059 micromolar), BH-12-205 (0.490 micromolar), BH-12-206 (0.840 micromolar), BH-12-207 (0.460 micromolar), BH-12-209 (1.1 micromolar), BH-12-210 (0.757 micromolar), BH-12-213 (0.382 micromolar), BH-12-214 (0.509 micromolar). Furthermore, the effect of these agents on biomarkers for EMT were investigated, showing down-regulation of vimentin, and N-cadherin and subsequent upregulation of E-cadherin and providing evidence to support reversion of the EMT and the malignant phenotype in colon cancer.

Conclusion: Benzimidazoles with extended amidine functionality were determined to be potent anti-tumor agents exhibiting cytotoxicity ranging from nanomolar to low micromolar range inhibition concentration fifty-percent and displayed impressive reversion of the EMT in metastatic SW620 colon cancer cells making these agents potential pharmaceutical agents for the treatment and prevention of metastatic colon cancer, and potentially many other types of human cancer.

Poster Title: Oral fluoroquinolone administration in respect to interacting substances: The pediatric diet dilemma

Primary Author: Jeffrey Butler, University of Colorado Denver, Colorado; **Email:** jeffrey.butler@ucdenver.edu

Additional Author (s):
Amanda Hurst

Purpose: Oral fluoroquinolones (FQs) remain as options for treatment of pediatric patients in certain circumstances (i.e. infections with multidrug-resistant organisms or as oral treatment when the only other option is a parenteral antibiotic). FQ administration should be separated from substances that contain divalent or trivalent cations to optimize bioavailability. Pediatric patients oftentimes receive concomitant interacting substances (feeds/multivitams), which impairs the absorption of the FQ and can put patients at risk for development of resistance. The purpose of this study was to describe the appropriate and inappropriate administration of oral FQs in relation to feeds and other substances in pediatric patients.

Methods: The Organizational Research Risk & Quality Improvement Review Panel at Children's Hospital Colorado approved this retrospective review. All pediatric patients less than 18 years of age who received oral ciprofloxacin or oral levofloxacin between January 1, 2016 and July 31, 2016 were included. Each FQ administration was evaluated regarding appropriateness. Ciprofloxaicn and levofloxacin administration data (including timing, formulation, and route), feeding data (including timing in relation to FQ administration), and oral medication data for medications with divalent or trivalent cations (including timing in relation to FQ administration) was collected to assess appropriateness of FQ administration. Interacting substances included those containing calcium, magnesium, zinc, and iron. Appropriate administration of levofloxacin and ciprofloxacin was defined based on the administration recommendations for each drug respectively from Micromedex®.

Results: There were a total of 539 administrations evaluated during the study period (ciprofloxacin, n=134 and levofloxacin, n=405) in 124 patients. Of the 539 administrations, 78% had an order for an interacting substance. A total of 330 administrations were considered inappropriate (61%). Of the 330 inappropriate administrations 259 (78%) were due to concomitant feeds, 43 (13%) were due to concomitant oral substances, and the remaining 28 (8%) were due to both concomitant feeds and oral substances. When evaluating levofloxacin versus ciprofloxacin administration, both had similar rates of inappropriate administration (248/405, 61% versus 82/134, 61%, respectively).

Conclusion: Concomitant administration of substances that impair FQ absorption is common in the pediatric population. Providers should take compliance with administration instructions into consideration when choosing a FQ for treatment of infections in the pediatric patient population, as receipt of interacting substances is common. Potential quality improvement measures identified include more descriptive administration comments within the electronic medical record and education of the pharmacy and nursing staff to insure appropriate timing of FQs.

Session-Board Number: 3-008

Poster Title: Analysis of antibiotic selection and duration of therapy for the treatment of aspiration pneumonia at an academic medical center

Primary Author: Khoa Nguyen, University of Colorado Denver Skagg's School of Pharmacy, Colorado; **Email:** khoa.2.nguyen@ucdenver.edu

Additional Author (s):
Bryan Knepper
Kati Shihadeh

Purpose: Aspiration pneumonia is an infection that is frequently treated in hospitalized patients; however, data on optimal treatment and duration of therapy for aspiration pneumonia is limited. The lack of data leads to ambiguity about the need to cover certain organisms including anaerobes, Pseudomonas aeruginosa, and methicillin-resistant Staphylococcus aureus (MRSA). This project was designed to describe the current practices in treating aspiration pneumonia at Denver Health Medical Center, compare current practices with treatment guidelines, and identify potential areas for antibiotic stewardship interventions.

Methods: This is a retrospective cohort study analyzing the treatment of adults with aspiration pneumonia. One hundred twenty-four patients with an ICD-9 code for aspiration pneumonia admitted between January 2015 and June 2015 were electronically identified. Of these, 99 patients who had aspiration and treated with antibiotics were randomly selected for review. Patient demographics, pertinent past medical history, microbiological culture data, and antibiotic treatment were reviewed. Pneumonia was classified as hospital-acquired aspiration pneumonia (HAAP) if onset of symptoms occurred 48 hours after hospital admission or community-acquired aspiration pneumonia (CAAP) if the patient presented with or developed symptoms of pneumonia less than 48 hours from admission. Antibiotics received by intensive care (ICU) patients were compared to those received by floor patients. Additionally, antibiotics used for patients with CAAP were compared to those with HAAP. Antibiotics use was evaluated individually and grouped as anti-pseudomonal beta-lactams, anti-MRSA, and anaerobic agents. Antibiotics and duration were compared to Denver Health's recommended agent of ceftriaxone for 5-7 days to determine how often internal guidelines were followed.

Results: Of patients reviewed, 72 percent were male and 43 percent had alcohol abuse. Fifty-four percent had CAAP; 46 percent HAAP. Respiratory cultures were obtained in 46 percent of patients. The majority of cultures was negative or grew mixed flora. Pseudomonas aeruginosa was cultured in 3 patients, and Staphylococcus aureus was cultured in 10 patients (susceptibilities not reported). Median treatment duration was 8 days (IQR 6, 13). Patients were treated with the follow frequency: anti-pseudomonal beta-lactam 47 percent, levofloxacin 28 percent, anti-MRSA 48 percent, anaerobice agent 54 percent, and ceftriaxone 33 percent. Fifty percent of ICU patients had CAAP versus 50 percent HAAP, whereas 58 percent of floor patients had CAAP versus 42 percent HAAP. Antibiotic selection among ICU patients is as follows: anti-pseudomonal beta-lactam 59 percent, levofloxacin 28 percent, anti-MRSA 61 percent, anaerobice agent 52 percent, and ceftriaxone 35 percent. Antibiotic selection among floor patients is as follows: anti-pseudomonal beta-lactam 33 percent, levofloxacin 29 percent, anti-MRSA 33 percent, anaerobice agent 56 percent, and ceftriaxone 31 percent. Treatment of HAAP versus CAAP is as follows: 63 versus 34 percent anti-pseudomonal beta-lactam, 39 versus 19 percent levofloxacin, 67 versus 32 percent anti-MRSA, and 54 versus 53 percent anaerobice agent.

Conclusion: About half of the patients received treatment against anaerobes which speaks to the uncertain need to cover these organisms. Anti-pseudomonal and anti-MRSA agents were used more frequently in ICU patients or patients with HAAP which was expected. Given the infrequency of these organisms cultured, using narrower spectrum agents could be an opportunity for antimicrobial stewardship. One way to do this would be to promote the use of ceftriaxone which is the recommended agent, but just 33 percent of patients received ceftriaxone. Lastly, patients were treated for longer than the recommended duration which provides another opportunity for antimicrobial stewardship.

Poster Title: Comparison of usability, accuracy, preference, and satisfaction between three once weekly GLP-1 receptor agonist pen devices

Primary Author: Anna Zhou, University of Colorado School of Pharmacy, Colorado; **Email:** anna.zhou@ucdenver.edu

Additional Author (s):
Jennifer Trujillo

Purpose: Glucagon-like-peptide-1 receptor agonists (GLP-1 RAs) are subcutaneous injection medications used to treat type 2 diabetes. Three GLP-1 RAs are available as once-weekly injections using prefilled, single-use, pen devices; each with different preparation and administration requirements. Complexity of medication administration requirements has been linked to poor adherence and inaccurate dosing. The purpose of this study was to compare the usability, accuracy, preference, and satisfaction between albiglutide (Tanzeum), dulaglutide (Trulicity), and exenatide XR (Bydureon).

Methods: This was an open-label, task and interview based study comparing three GLP-1 RA pen devices. Assessments were conducted with 30 health care professional participants at one major university medical campus. The study was approved by the investigational review board and informed consent was obtained from each participant. During a 45-minute session in a private room with a computer, each participant watched the products' instructional videos in a randomized order. Subsequently, each participant demonstrated and verbalized how to use the pen devices. Accuracy and usability were assessed by one evaluator. Usability and accuracy performance outcomes were time taken to complete the administration demonstration and percent of required administration steps demonstrated correctly. Participants completed a 6-item usability survey for each device using a 5-point Likert scale where 5 was "very easy" and 1 was "very difficult" and then completed a 5-item preference survey using a ranking scale where 1 was "most preferred" and 3 was "least preferred." Continuous and categorical variables were compared using the one-way analysis of variance (ANOVA) and Fisher's Exact Test, respectively. User satisfaction ratings were compared using the Mann-Whitney test. Statistical significance was set at p less than or equal to 0.05.

Results: Average demonstration time was shorter with dulaglutide compared to exenatide XR and albiglutide (1.37, 2.30, 3.53 minutes, respectively; p less than 0.0001 for both). Based on manufacturers' instructions, the number of required administration steps for dulaglutide, exenatide XR, and albiglutide was 6, 16, and 23 respectively. Accuracy in demonstrating these steps was 84.4% with dulaglutide, 83.8% with exenatide XR, and 75.9% with albiglutide (p less than 0.05 for dulaglutide vs. albiglutide). Dulaglutide was easier to prepare for injecting than exenatide XR and albiglutide (average Likert scale scores 4.70, 3.47, 2.87 respectively; p less than 0.001 for both). Dulaglutide was easier to hold stable when injecting compared to exenatide XR or albiglutide (average Likert scale scores 4.83, 4.47, 4.30 respectively; p less than 0.05 for both). Participants found it easier to recall administration steps for dulaglutide compared to exenatide XR and albiglutide (average Likert scale scores 4.40, 3.17, 2.27 respectively; p less than 0.001 for both) and easier for exenatide XR compared to albiglutide (p less than 0.05). Twenty-eight participants (93 percent) preferred dulaglutide in overall preference, ease of use and demonstration, confidence in full dose delivery, and likelihood of recommending to other healthcare professionals (p less than 0.0001 for all).

Conclusion: Out of the three once weekly GLP-1 RAs studied, dulaglutide was associated with the highest user satisfaction, fastest demonstration with the fewest errors compared to exenatide XR and albiglutide. Most participants preferred dulaglutide overall.

Poster Title: Evaluation of the use of systemic corticosteroids in patients with an acute exacerbation of COPD (AECOPD) and a diagnosis of pneumonia

Primary Author: Tyler Scholl, University of Colorado Skaggs School of Pharmacy and Pharmaceutical Sciences, Colorado; **Email:** tyler.scholl@ucdenver.edu

Additional Author (s):
Sheryl Vondracek

Purpose: COPD is a leading cause of morbidity and mortality worldwide, and pneumonia is a leading cause of death from infectious disease in the US.
Studies of systemic corticosteroids in patients with pneumonia have shown conflicting benefits and potential harms, whereas studies in patients with an AECOPD have shown significant benefits. Although these conditions are often comorbid, studies of systemic corticosteroid use in patients with both an AECOPD and pneumonia are lacking.
This study aimed to gain a better understanding of the risks and benefits of the use of systemic corticosteroids in patients with an AECOPD and pneumonia.

Methods: The institutional review board approved this retrospective chart review. We collected data on patients 40-89 years of age admitted to the University of Colorado Hospital between 7/1/12 and 5/20/16.
Patients with a hospital diagnosis of either COPD or obstructive chronic bronchitis with exacerbation and pneumonia, based on ICD-9 and ICD-10 codes, were examined for inclusion. Exclusion criteria were hospital-acquired pneumonia, no radiographic evidence of pneumonia, immunocompromised status, asthma or other lung disease, death during hospital stay, septic shock with the need for pressors, and systemic corticosteroid use within 30 days of admission. It was determined that with a population mean length of stay of 8 days and standard deviation of 4 days, to detect a 2 day length of stay difference, which we believed to be clinically significant, with 80-percent power and an alpha level of 0.05, we needed 64 patients in each group.
We compared patients who received systemic corticosteroids to those who did not. Patients who were administered systemic corticosteroids for more than one dose, or for one dose with a

discharge course of systemic corticosteroids immediately thereafter qualified for the steroid group.

The primary outcome assessed was length of hospital stay (LOHS) using a 2-tailed t-test. Secondary outcome was treatment failure, a composite of ICU admission, ventilation, escalation of steroid therapy, and 30-day AECOPD or pneumonia readmission using 2-tailed Fisher's exact test.

Results: There were 138 patients included in this study. The average age was 67.2 years, 57-percent were male and 74-percent were white. There were 89 patients in the steroid group and 49 patients in the non-steroid group. There were no statistically significant differences in the background characteristics between groups.

There was no statistically significant difference in LOHS between patients in the steroid group and the non-steroid group, with a mean LOHS of 4.7 plus/minus 3.2 vs. 4.2 plus/minus 2.1 days, respectively (p=0.273).

There was no statistically significant difference in treatment failure between the steroid and non-steroid groups (12-percent in the steroid group and 8-percent in the non-steroid group, p=0.5733). None of the components of treatment failure were significantly different between the two groups.

There was no statistically significant difference between the two groups for any of the adverse events examined (hyperglycemia, psychiatric side effects, and edema).

There was no difference in mean LOHS for patients who went to the ICU between the two groups (p=0.090). The mean LOHS for patients with severe pneumonia was longer in the steroid group compared to the non-steroid group (6.0 plus/minus 4.0 vs. 4.3 plus/minus 1.8 days, p=0.025).

Conclusion: In patients with an AECOPD and pneumonia, there was no statistically significant difference in LOHS between patients that received a course of systemic corticosteroids and those that did not. The use of systemic corticosteroids in this population also did not reduce the frequency of treatment failure or any of its components.

This study suggests that the use of systemic corticosteroids in patients with an AECOPD and pneumonia does not provide a clinical benefit, especially in the case of severe pneumonia. More research must be done before systemic corticosteroids are used routinely in this patient population with both AECOPD and pneumonia.

Poster Title: Retrospective review of the use of as needed hydralazine and labetalol for the treatment of acute hypertension in hospitalized medicine patients

Primary Author: Michelle Gaynor, University of Colorado Skaggs School of Pharmacy and Pharmaceutical Sciences, Colorado; **Email:** michelle.gaynor@ucdenver.edu

Additional Author (s):
Sheryl Vondracek

Purpose: Prevalence of hypertension in hospitalized patients is greater than 50 percent. Treatment of chronic hypertension is based on evidence-based guidelines. No guidelines exist on the management of hypertensive urgency/severe asymptomatic hypertension in the hospitalized patient, nor have studies demonstrated benefits from BP lowering in these patients. Studies have shown the unnecessary use of PRN IV hydralazine and labetalol for management of severe asymptomatic hypertension in hospitalized patients. The purpose of our study was to evaluate the use of PRN labetalol and hydralazine (oral or IV) in hospitalized medical patients and to examine the potential negative outcomes associated with their use.

Methods: The Colorado Multiple Institutional Review Board approved this retrospective chart review. Data was collected on 250 patients admitted to the University of Colorado Hospital (UCH), an urban academic medical center, between November 2014 and April 2016. Patients were enrolled if they were 18-89 years of age, admitted to a UCH internal medicine team, and received at least one dose of as needed oral or IV hydralazine and/or labetalol regardless of previous antihypertensive treatment or hypertension diagnosis. Exclusion criteria included ICU admission, pregnancy, and recent CVA (prior to admission) in the last six months, or patients admitted for hypertensive emergency, cerebral hemorrhage, hypertensive encephalopathy, aortic dissection or aneurysm. The primary outcome was to describe the use of as needed antihypertensive medications in hospitalized medicine patients. Secondary outcomes included assessment of potential harm associated with acute treatment of severe asymptomatic hypertension, and description of changes made to patient's antihypertensive medication regimens during hospital stay and on discharge.

Results: A total of 573 doses of PRN oral or IV hydralazine or labetalol were administered to 250 patients. Oral hydralazine was the most commonly administered PRN antihypertensive (521 doses, 90.9 percent), with 25mg or 50mg being the most commonly administered doses (384, 73.7 percent). Mean BP before administration of PRN antihypertensive medication was 183/93 plus or minus 14/13 mmHg. Forty-one percent of PRN administrations were given for a SBP less than 180mmHg or DBP less than 110mmHg (threshold for hypertensive crisis definition). The BP reductions within 6 hours of PRN antihypertensive administration was less than 10 percent in 13 percent of administrations, 10-25 percent in 50 percent of administrations, and greater than 25 percent in 22 percent of administrations. Fifteen percent of administrations resulted in no BP improvement. No patients were assessed for the presence of end-organ damage prior to administration of PRN antihypertensive medication. There were no serious adverse events related to the PRN antihypertensive administration. Despite receiving at least one PRN antihypertensive medication during their hospital stay, 41 percent of patients were not continued on their home antihypertensive medication(s) while hospitalized, and 62 percent of patients did not have their home antihypertensive regimens intensified at discharge.

Conclusion: Oral hydralazine is commonly used for acute BP lowering in hospitalized internal medicine patients. Administration BP thresholds for PRN antihypertensive medication are often less than what is used to define hypertensive crisis. Many patients are prescribed PRN antihypertensive medications instead of being continued on their home antihypertensive regimens. Despite receiving PRN antihypertensive medication while hospitalized, many patients did not have the intensity of their home antihypertensive regimens increased. Internal medicine providers should be educated about the use of as needed antihypertensive medication for the management of severe asymptomatic hypertension in the hospital setting.

Poster Title: Ofatumumab as an alternative to rituximab in pediatric patients who require anti-CD20 monoclonal antibody therapy: A case series at Children's Hospital Colorado

Primary Author: Rachel Visage, University of Colorado Skaggs School of Pharmacy and Pharmaceutical Sciences, Colorado; **Email:** rachel.visage@childrenscolorado.org

Additional Author (s):
Amy Carver

Purpose: Ofatumumab is a fully human monoclonal antibody that induces B cell lysis by binding to the small and large loops of the CD20 molecule on the surface of the B cell. Currently ofatumumab is only FDA approved for the treatment of chronic lymphocytic leukemia in adults, but could be a beneficial therapy in patients with various B-cell mediated diseases who cannot receive chimeric rituximab due to hypersensitivity, intolerance, or refractory disease. This case series illustrates the off-label use of ofatumumab in two patients at Children's Hospital Colorado. Patient 1 is a 9-year-old male who received an allogeneic hematopoietic stem cell transplant at age 7 in attempt to cure his congenital dyserythropoietic anemia after two prior stem cell transplant failures. He has a history of severe intolerance/allergy to rituximab exhibited by multiple instances of secretory diarrhea, vomiting, and hives which recurred after a desensitization trial of escalating doses of rituximab. As a component of the preparative regimen for the third engraftment attempt, the health care team chose to initiate ofatumumab in order to deplete B cells and reduce potential confounding alloantibodies while minimizing the risk of intolerance or hypersensitivity to treatment. The regimen included four doses of ofatumumab: 175 mg/m2 once, followed by 580 mg/m2 every 7 days for three doses. The infusions were well tolerated with the exception of one instance of agitation, during which the infusion was paused and subsequently resumed without incident. The patient did not experience any complications related to ofatumumab therapy. He received the remainder of his preparative regimen followed by successful engraftment of the third stem cell transplant. Patient 2 is an 8-year-old male who received an allogeneic stem cell transplant in attempt to cure his X-linked adrenoleukodystrophy. As a complication of stem cell transplantation, he developed autoimmune hemolytic anemia and was readmitted with a hemoglobin of 4.5 g/dL. Upon admission, he received red blood cell transfusions and was treated with methylprednisolone and rituximab in addition to cyclosporine therapy. The patient responded

to treatment and was subsequently tapered off of the methylprednisolone while still receiving rituximab and cyclosporine. During the attempt to taper methylprednisolone, his hemolytic anemia flared and he was re-treated with methylprednisolone, rituximab, and mycophenolate mofetil. After responding to treatment and a second attempt to taper methylprednisolone, he experienced another flare of hemolytic anemia despite continuation of rituximab and mycophenolate. Due to the suspicion that the patient was no longer responding to rituximab as a result of potential anti-murine immunoglobulin antibody production, he was started on ofatumumab for alternative immunosuppressive therapy. The patient received an initial ofatumumab dose of 175 mg/m2, which was followed by 580 mg/m2 weekly for three weeks, then every other week for four weeks, and then once a month. After changing therapy from rituximab to ofatumumab, signs and symptoms of the hemolytic anemia flare resolved without complications or adverse effects of treatment. Although further experience is necessary in order to determine the safety and efficacy of ofatumumab in pediatric patients with various B-cell mediated conditions, it may play an important role as salvage therapy in patients who cannot receive rituximab due to hypersensitivity or refractory disease.

Poster Title: Pharmacy intern hospital rounding, performance of random audits, and compilation of survey feedback improves IV smart pump compliance in a community hospital

Primary Author: Whitney Pittman, University of Colorado Skaggs School of Pharmacy and Pharmaceutical Sciences, Colorado; **Email:** whitney.pittman@ucdenver.edu

Additional Author (s):
Amee Replogle
Elise Mangione
Shreaf Khattab
Christopher Zielenski

Purpose: Intravenous smart pumps are designed to deliver medications to patients at precise rates and volumes. Pumps include programmable parameters that allow for development of drug libraries and provide medication dosing guidelines in terms of concentrations, dose limits, and patient populations. These parameters are necessary for safe medication administration but may become a nuisance. This can lead to alert fatigue, override of program limits, and decreased utilization of smart pump technology. The purpose of this project was to improve smart pump compliance, medication administration processes, and patient safety in accordance with ISMP guidelines through behavioral change and reduction of alert fatigue.

Methods: Pharmacy intern involvement consisted of unit rounding and random IV pump audits, which are easy metrics for nurse managers to use as improvement opportunities. Surveys were disseminated to nursing staff to identify issues that hindered compliance. A safety newsletter highlighted the prominence of smart pump use. Participation in REMEDI collaborative enabled pharmacy interns to analyze data regarding IV smart pump utilization. Additionally, other hospital sites were contacted about smart pump practice recommendations. This allowed students to compare drug libraries from multiple institutions in order to reduce alert fatigue, refine and augment drug libraries, and provided a benchmark of compliance rates. Data was further evaluated for areas to provide targeted nurse education on proper medication administration. Information gathered was compiled to make changes to the drug library in order to increase compliance and reduce alerts. Medication entries were expanded and enhanced in existing libraries based on feedback from nursing staff and opportunities identified

through REMEDI. Pharmacy students answered questions that came up during rounding, encouraged communication, educated on the importance of smart pump utilization, and clarified misconceptions. In addition to student efforts, compliance rates were distributed monthly to nursing unit managers and discussed at task force meetings, quality steering committees, leadership huddles, patient safety council, pharmacy and therapeutics committees, and medication use safety team meetings.

Results: Through the efforts of pharmacy students, compliance rates regarding the use of IV smart pumps increased. Over the project time period, pharmacy students built a drug library for the pediatric unit of the hospital, which directly correlated with increased nurse compliance of that unit. The percentage of alerts per infusion that used the drug library and the percentage of soft limit overrides decreased. Barriers to using IV smart pumps also decreased. Compared to the number of times that nurses used the drug library, soft limit edits and hard limit frequencies were greater, meaning that a positive change was observed. Pharmacy interns spent approximately 65 hours engaging with nursing staff, which resulted in adding 25 new drug entries to the libraries of various clinical care areas and updating five soft and hard limits in order to decrease the number of alerts. Drug editions and edits were all presented at medication use safety team meetings held quarterly. There was a significant decrease in the frequency of alerts and the percentage of alert overrides, as well as an increase in smart pump compliance rates.

Conclusion: This project provided insight into the impact of pharmacy student involvement of IV smart pump operations in a community hospital. Student efforts included nurse education, additions to the drug library, and updates of soft and hard limits. Pharmacy intern participation in IV smart pump quality improvement initiatives leads to a positive impact of smart pump utilization, which simultaneously results in enhancement of patient safety.

Submission Category: Emergency Medicine/ Emergency Department/ Emergency Preparedness

Submission Type: Evaluative Study

Session-Board Number: 3-014

Poster Title: Evaluation of Epinephrine Administration in the Emergency Department

Primary Author: Megan Rieder, University of Colorado Skaggs School of Pharmacy and Pharmaceutical Sciences, Colorado; **Email:** megan.rieder@ucdenver.edu

Additional Author (s):
Benjamin Kleeman
Philip Leong
Casey Melvin
Joseph Oropeza

Purpose: Severe allergic reactions present to the emergency department with varied symptom severity; therefore it is imperative to provide adequate care quickly to prevent negative outcomes. International guidelines recommend epinephrine be administered intramuscularly as first line treatment for adults with such reactions. Studies serving as the basis for the recommendation demonstrate superior absorption when administered in the lateral thigh versus the deltoid. Despite epinephrine being first line, errors surrounding administration are common. The objective was to assess the use of epinephrine during allergic reactions to determine appropriateness of dose, route, and location based on current practice at twelve regional emergency departments.

Methods: This analysis was a multi-center, retrospective, observational cohort study conducted in twelve regional emergency departments. Data was collected from August 1, 2013 to December 31, 2015. Patients were identified through automated dispensing machine reports for epinephrine 1mg/ml ampule from emergency department machines. Data from the reports were used to query electronic medical records to obtain predefined variables. Defined variables included gender, age, route, specific site of administration, and epinephrine dose charted. Data was then compiled to identify the appropriateness of administration site, route, and dose as a health-system wide process improvement project.

Results: From August 1, 2013 to December 31, 2015, epinephrine was administered 911 times to 869 patients who presented to one of the twelve emergency departments analyzed. Of those 911 administrations, 756 (83%) were administered into areas other than the lateral thigh. The

deltoid was the most frequent administration site as 664 (72.9%) injections were given in that location, while only 155 (17%) injections were given into the preferred location of the lateral thigh. There were 58 (6.4%) injections given into other locations that included the gluteus and abdomen, while 34 (3.7%) injections were administered intravenously. The most common administration route was intramuscular (659 injections, 72.3%), followed by subcutaneous (218 injections, 23.9%), then intravenous (34 injections, 3.7%). Doses of 0.3 – 0.5 mg of epinephrine were given 761 (83.5%) times, however 90 (9.9%) injections were given that were less than 0.3mg while 60 (6.6%) injections were given at doses greater than 0.5mg.

Conclusion: International guidelines recommend injecting epinephrine 0.3-0.5mg intramuscularly into the lateral thigh for allergic reactions. Based on pharmacokinetic properties, superior absorption is achieved with epinephrine administration into the lateral thigh. Data collected supports the need for additional education to ensure proper administration as 756 (83%) epinephrine administrations evaluated were not administered into the correct location and 150 (16.5%) incorrect doses were given. While patient outcomes were not evaluated, choosing the optimal injection site might be clinically relevant during emergency situations. This analysis is likely representative of other emergency departments, thus indicating a need for increased awareness of proper epinephrine administration.

Submission Type: Descriptive Report

Session-Board Number: 3-015

Poster Title: Regulating human kindness: The call for safe and accessible donor human milk

Primary Author: MaLaura Creager, University of Colorado Skaggs School of Pharmacy and Pharmaceutical Sciences, Colorado; **Email:** malaura.creager@ucdenver.edu

Purpose: In both hospital and outpatient settings, donor human milk (DHM) is prescribed or purchased over the counter for term infants and promoted for nourishment and immune support. Additionally, neonatal intensive care units promote and utilize DHM with nutrient fortification for use as prophylaxis against necrotizing enterocolitis in very low birth weight pre-term infants. This research examines how healthcare systems are incentivized to provide DHM, explores the public health benefits and concerns, and reviews the current regulatory status of DHM with a focus on the jurisdiction of the Federal Food and Drug Administration (FDA).

Methods: Public health benefits and concerns were evaluated through a search of evidence and clinical practice guidelines for DHM by the American Academy of Pediatrics, the American Society of Parenteral and Enteral Nutrition, the World Health Organization, and the US Breastfeeding Committee. Popular media and literature searches were evaluated in the following areas: current market share of human milk exchange held by commercial vs non-profit milk banks, current processing and shipping policies of milk banks, human milk banking history, and peer-to peer milk sharing practices. Regulatory practices were reviewed by examining the Federal Food, Drug, and Cosmetics Act; Public Health Service Act; Code of Federal Regulations; US Surgeon General's position statements; Human Milk Banking Association of America's guidelines for establishing a human milk bank; Joint Commission (JCAHO) National Quality Core Measures; and FDA safety alerts.

Results: JCAHO has included DHM as an option to satisfy the exclusive breast milk feeding performance measure, which Centers for Medicare and Medicaid Services use in calculating a hospital's total performance score. Thus, hospitals are incentivized to provide DHM to increase reimbursement. DHM is a public health resource in the prevention of necrotizing enterocolitis and the resultant costs and complications of short bowel syndrome in adults. The non-profit Human Milk Banking Association of America has guidelines based on federal regulations for plasma donation, and most commercial milk banks publish their manufacturing process.

Currently, only those establishments located in states with banked milk regulations are inspected by outside agencies to ensure that the product is safe for infant consumption. Federal regulations are needed to protect the public from medication or viral and bacteriological pathogen exposure should the milk banks fail to adhere to current good manufacturing processes. There are no mandatory reporting requirements for infants who experience illness or death from infectious disease after consumption of DHM. Per the Federal Food, Drug, and Cosmetics Act, DHM is both a food and a drug prescribed for the prevention of a human disease. Current regulations either fail to appropriately address or specifically exclude DHM.

Conclusion: As a food product for nourishment and immune support and as a human tissue product used for the prevention of a human disease, DHM is under the FDA's jurisdiction. However current regulations fail to provide adequate guidance and new regulations are needed to support the public health benefit and reduce the public health risk of DHM.

Session-Board Number: 3-016

Poster Title: Treating epistaxis in patients with hemophilia using a novel compounded drug formulation: a stability study

Primary Author: Kyle Troksa, University of Colorado Skaggs School of Pharmacy and Pharmaceutical Sciences, Colorado; **Email:** kyle.troksa@ucdenver.edu

Additional Author (s):
Alison Schomerus
Desiree Hill
Paul Limberis

Purpose: Epistaxis is common in patients with hemophilia. It is typically treated using nasal packing and oral antifibrolytic medications (i.e. aminocaproic acid and tranexamic acid), which are often not sufficient to resolve a bleed. Some hemophilia treatment centers have used compounded aminocaproic acid nasal spray to improve epistaxis resolution times; however, there have been a lack of data to support the stability of this product once it has been compounded, preventing treatment centers from dispensing it. The purpose of this study is to analyze the stability of compounded aminocaproic acid nasal spray to accurately assign a beyond use date (BUD).

Methods: Aminocaproic acid nasal spray 100 mg/mL was compounded in a non-sterile setting according to pharmacy protocol. The compounded product was then sent to a local analytical laboratory and stored at either room temperature or 2 degrees Celsius. Samples were taken from each temperature setting weekly and assessed using liquid chromatography-mass spectrometry (LCMS). 5 μL injections were made on an Agilent 1260 HPLC with tandem 6120 single quad mass spectrometer. Fragmentation was used to assess the presence of degradation products in each sample, so as to ensure consistency of active pharmaceutical ingredient over time. First, total ion count was monitored and quantified with the fragmentor voltage set to 0 V. Fragmentation was then monitored with the fragmentor voltage set to 70 V. The total ion count and fragmentation pattern were consistent in each sample and indicate no appreciable appearance of degradation products. Data collected over 25 weeks were then reported, analyzed, and graphed over time using Microsoft Excel.

Results: After 25 weeks of testing, aminocaproic acid nasal spray 100 mg/mL retains potency and is stable at both room temperature and 2 degrees Celsius.

Conclusion: Aminocaproic acid nasal spray 100 mg/mL can be appropriately dispensed with a BUD of 6 months and stored at either room temperature or in the refrigerator, as it has shown to be chemically stable after this time in these temperature settings.

Poster Title: Impact of pharmacy workup program on guideline-driven recommendations for aspirin, angiotensin converting enzyme inhibitors/angiotensin II receptor blockers, and statin therapies

Primary Author: Malia Malihi, University of Colorado Skaggs School of Pharmacy and Pharmaceutical Sciences, Colorado; **Email:** malia.malihi@ucdenver.edu

Additional Author (s):
Nancy Adams
Lindsay Case
Lesleigh Potter

Purpose: Pharmacist collaboration with providers has a positive impact on patient outcomes including decreasing cardiovascular risk through reaching blood pressure and cholesterol goals following standards of care based on guidelines. At a federally qualified health center (FQHC) in Colorado, a pharmacy pre-visit program was implemented to increase the number of patients meeting standards of care. The objective of reviewing this quality improvement initiative was to evaluate the impact of the pharmacy pre-visit program related to increasing appropriate utilization of guideline-driven standards of care for aspirin, angiotensin converting enzyme inhibitors (ACEi)/angiotensin II receptor blockers (ARB), and statin therapies.

Methods: To establish baseline utilization rates, a retrospective chart review was performed to identify patients at risk for cardiovascular disease. Charts eligible for review were identified using the electronic medical health record (Greenway Success EHS) from a FQHC in the Denver area. Patients included in the review were between the ages of 40 and 79 years old and seen in the clinic in the past 12 months (November 2014 to November 2015). The program was implemented in June 2016 utilizing a workup tool for pharmacy services to review the chart of each patient scheduled the following day. Charts were evaluated to verify the patient was receiving treatment per the standards of care. Notes were placed in patient charts with recommendations to the providers to better align treatments with guideline-based standards. The statin therapy recommendations were made based on 2013 American College of Cardiology/American Heart Association (ACC/AHA) guidelines. The ACEi or ARB therapy recommendations were made based on the 2014 American Society of Hypertension-

International Society of Hypertension (ASH-ISH) guidelines and 2016 American Diabetes Association (ADA) guidelines if the patient had diabetes. The aspirin therapy recommendations for primary prevention were made based on the 2016 U.S. Preventive Services Task Force (USPSTF) guidelines and ADA guidelines for diabetic patients. These notes placed over a 10-week period were reviewed to determine the percent increase of patients meeting standards of care.

Results: The baseline utilization review identified 406 patients in total. Of this population, 187 (46.1 percent) were eligible for statin therapy, but only 70 patients (37.4 percent) were being appropriately treated. Amongst the 406 total patients, 71 patients were eligible to receive aspirin, however 46 patients (64.8 percent) were not on aspirin. Amongst 406 patients, 100 patients had diabetes, 34 of which were eligible for an ACEi or ARB therapy. However, 6 patients (17.6 percent) were not being treated with an ACEi or ARB therapy.

After the pharmacy pre-visit program implementation, 349 total patients were seen over a 10-week period by the providers and 124 patients met the inclusion criteria for review of the pharmacy pre-visit workup recommendations. Before pre-workups, 58 percent of patients who qualified for statin therapy were on appropriate therapy, 32 percent of patients qualified for aspirin therapy were on appropriate therapy, and 94 percent of patients qualified for ACEi/ARB therapy were on appropriate therapy. After pre-workups, 65 percent of patients who qualified for statin therapy were on appropriate therapy, 48 percent of patients who qualified for aspirin therapy were on appropriate therapy, and 94 percent of patients who qualified for ACEi/ARB therapy were on appropriate therapy.

Conclusion: The daily pharmacy pre-visit program was a quality improvement initiative that had a positive impact on guideline-recommended standards of care within the FQHC and will continue to be utilized in the future. Before pharmacist intervention, the clinic was already exceeding national averages of standards of care for aspirin, ACEi/ARB, and statin therapy. The daily pharmacy pre-visit program was associated with an increase in prescriber adherence to guideline recommendations for aspirin (16 percent increase) and statin (7 percent increase) therapies. Guideline recommended usage of ACEi/ARB therapy remained the same, just 6 percent below every patient who qualified.

Poster Title: Disease modifying therapies and other potentially teratogenic medications and concurrent contraceptive use in women with multiple sclerosis

Primary Author: Christina Wern, University of Colorado Skaggs School of Pharmacy and Pharmaceutical Sciences, Colorado; **Email:** christina.wern@ucdenver.edu

Additional Author (s):
Jacquelyn Bainbridge
Laura Borgelt

Purpose: Multiple sclerosis is a chronic inflammatory disease that affects twice as many women than men and usually manifests in women of childbearing age. Because of the chronic nature of this disease, it is not uncommon for women to be prescribed potentially teratogenic disease modifying therapies as well as other symptomatic medications. The aim of the study was to determine the rate these medications were prescribed and the concurrent use of contraceptive methods and/or documentation of contraceptive counseling or pregnancy planning. When prescribed, the appropriateness of the contraception method was assessed.

Methods: This was a retrospective, observational study of women ages 15-44 with multiple sclerosis of childbearing ability who were prescribed at least one potentially teratogenic disease modifying therapy or supporting therapy from October 1, 2014 to September 30, 2015 at the Rocky Mountain MS Center and outpatient neurology clinic at the University of Colorado Anschutz Medical Campus. The Colorado Multiple Institutional Review Board approved this study. Patients that met our inclusion criteria were identified using ICD-10-CM codes in the EPIC™ electronic health record database and were included in the study if they were a woman between the ages 15-44 years of age with childbearing ability who were diagnosed with multiple sclerosis and given at least one prescription for a potentially teratogenic medication (previous FDA category D or X) during the study time frame. Exclusion criteria included women less than 15 years of age or older than 44 years of age with multiple sclerosis, women who had surgical sterilization, women with partners who were documented to be surgically sterile (e.g. vasectomy), women who had a hysterectomy, acute use of medication (e.g. 14 days or less), women without multiple sclerosis, and men.

Results: A total of 399 patient charts were screened. One hundred twelve women with multiple sclerosis and a mean age of 35 years were included in the study. Of these women, 81% were prescribed one potentially teratogenic medication and 19% were prescribed two of these medications. Only 31% (35) of the women in this study had a documented contraception method. Of these 35 patients, 74% (26) were on an oral combined hormonal contraceptive, 11% (4) had an intrauterine device (levonorgestrel or copper), 9% (3) had a progesterone-only implant, 6% (2) used a combined hormonal contraceptive vaginal ring, 11% (4) used male condoms, and 3% (1) used spermicide. Of the patients on an oral combined hormonal contraception, 31% (8) were also on a disease modifying therapy or other medication that lowers the efficacy of the contraception. Furthermore, only 5% (6) of patients in the study population received contraception counseling and/or pregnancy planning. The remaining 95% of the study population did not have any documentation of contraception counseling and/or pregnancy planning. Of the 21% of patients on two potentially teratogenic medications during the study period, only 5% (1) had documented pregnancy planning.

Conclusion: There was minimal documentation regarding contraception use in women with multiple sclerosis of childbearing ability and many were not using any contraception method while on a potentially teratogenic medication. Of the patients on a contraception method, 31% were on a disease modifying or symptomatic therapy that lowers the efficacy of said method. This study demonstrates the need for providers to discuss with these women the risks and benefits of both disease modifying and symptomatic therapies for multiple sclerosis, the importance of contraceptive counseling and/or pregnancy planning, and the need to select an appropriate contraception method when pregnancy is not desired.

Poster Title: Multicenter restrospective observational study to examine the efficacy and thrombotic events in patients receiving Idarucizumab (PRAXBIND®).

Primary Author: Joshua Sanchez, University of Colorado Skaggs School of Pharmacy and Pharmaceutical Sciences, Colorado; **Email:** joshua.r.sanchez@ucdenver.edu

Additional Author (s):
Stefanie Stafford
Eric Whittenberg
Nicolas Tinker

Purpose: Idarucizumab, (Praxbind®), is a monoclonal antibody approved for the reversal of anticoagulant effects related to dabigatran in the event of an emergent surgery/procedure or life threatening bleeds. In the initial FDA approval, only 3 trials with healthy volunteers, a total of 224 subjects were treated. Similarly, in the RE-VERSE AD trial only 123 dabigatran-treated patients were administered idarucizumab and 5 of those patients (0.04%) reported thrombotic events. This project was designed to characterize the current utilization of idarucizumab to assess safety and efficacy.

Methods: A retrospective analysis was performed starting when idarucizumab was added to Centura Health formulary. Starting January 2016, a system wide database search of all Colorado Centura Health hospitals for documented idarucizumab administration was performed. Inclusion criteria was any patient whom received idarucizumab. Patient charts were reviewed to gather data for idarucizumab indication and dosing regimen, thrombotic events and patient outcomes were recorded. A subgroup analysis of thrombotic events was performed in patients with renal disease as it has been reported that this patient population experiences higher blood concentration levels.

Results: Review of 14 patient charts, from 6 Colorado Hospitals, indicating administration of idarucizumab, occurred between January 2016 and September 2016. Patient population consisted of 12 males (85.71%) and 2 females (14.29%) with an average age range of all patients of 76.5 SD+/-9.58. 5 (35.7%) patients were in need of reversal due to clinically relevant bleeding and 9 (64.25%) patients were in need of urgent surgery. A one-time dose of 5 grams

was administered to 12 patients (85.71%) and 2 patients received 2 doses of 2.5 grams (14.29%). The patient population also included 4 patients (28.5%) with renal dysfunction. Data obtained revealed no thrombotic events occurring from idarucizumab administration through discharge. 2 patients expired during the observation period, but were unrelated to idarucizumab administration. No difference was seen in regards to patient outcomes or thrombotic events when looking at the different dosing regimens. Since no thrombotic events were reported, we can conclude that renal dysfunction did not put patients at an increased risk of thrombotic events despite previous trial reports of this patient population having higher drug levels in the blood.

Conclusion: Our observations indicate no episodes of thrombotic events during the hospitalization including those with renal dysfunction and also when using different dosing regimens. Based upon these data we can conclude that the standard dosing of 5 gm once can safely be used in patients with renal dysfunction with no increased risk of thrombotic events. When looking at the different dosing regimens, we also see no difference in outcomes or adverse events therefore using the manufacturer recommendation of a one-time dose of 5 grams should be used in patients requiring urgent reversal from bleeding related to dabigatran.

Submission Type: Evaluative Study

Session-Board Number: 3-020

Poster Title: Evaluation of a smart labeling system and its impact on charge capture and medication errors

Primary Author: Ferras Bashqoy, University of Colorado, Denver, Colorado; **Email:** ferras.bashqoy@ucdenver.edu

Additional Author (s):
James Thomas
Kailynn DeRonde
Casey Dugan
Patrick Guffey

Purpose: Patient safety challenges unique to the perioperative setting can potentially increase the risk of medication errors (MEs). Perioperative ME rates have been reported as high as 1 per 20 cases and have been attributed to the medication management system and safety checks used in each hospital. The purpose of this collaborative project between the Department of Anesthesia and Department of Pharmacy was to evaluate the impact of the Codonics Safe Label System (SLS) on MEs and charge capture. Secondary objectives included identifying factors related to charge capture associated with MEs and adverse drug events.

Methods: The Children's Hospital Colorado Quality Improvement Review Panel approved this retrospective chart review. An EPIC report identified all perioperative patients from November 2015 to July 2016. Patients of all ages were included if they received at least one medication from the Omnicell Anesthesia Workstation (AWS) in the main operating rooms (ORs) or procedure center. Cardiac OR, maternal-fetal OR, and off-site encounters were excluded. Codonics SLS machines were installed in four ORs in February 2016. Data were not collected for 2 months after installation to allow for staff training. Data collection post implementation was restricted to the four rooms that housed a Codonics SLS machine. Data collected included date and time of procedure, patient medical record number, procedure location, staffing anesthesiologist, medications with charge capture discrepancy, and medication cost. Medication costs were updated before and after implementation to represent actual cost. The primary outcome measure was the frequency and cost associated with discrepancies between the documented medication administration report in EPIC and the medications charged to the

patient. Secondary outcome measures included medication name and route of administration. It was determined that a minimum sample size of 1,354 patients would yield an 80% power to detect a difference between groups. A one-tailed z-score test was used to analyze the difference between two population proportions. All analysis was performed with PRISM GraphPad, version 6.

Results: There were 1,014 patients in the pre-Codonics group and 958 patients in the post-Codonics group. Implementation of Codonics SLS improved charge capture by 3.62%. This improvement is statistically significant (z-score 6.66, p-value < 0.05). A charge capture improvement of $26,774 and revenue realization of $9,639 were observed. These values were extrapolated to a potential annual savings of $384,172 per 30,000 patients. Medications most frequently associated with discrepancies were topical lidocaine (n=100, 12%), cefazolin (n=99, 12%), ketorolac (n=99, 12%), and dexamethasone (n=94, 11%). Route of administration most frequently associated with discrepancies were intravenous (n=681, 83%) and topical (n=144, 17%).

Conclusion: Medication management systems with built-in safety checks can improve charge capture and have the potential to decrease ME. Investigators expect to see an increase in revenue after large-scale implementation of Codonics SLS at Children's Hospital Colorado. More research is needed to evaluate the clinical impact of Codonics SLS in reducing ME.

Submission Type: Case Report

Session-Board Number: 3-021

Poster Title: Risk of thrombocytopenia in patients on telavancin

Primary Author: Su Bin Park, GA-PCOM School of Pharmacy, Georgia; **Email:** subinpa@pcom.edu

Additional Author (s):
Kuran Kusan
Edoabasi McGee

Purpose: Telavancin is a glycopeptide antimicrobial indicated for patients with complicated SSTI and hospital acquired or ventilator acquired bacterial pneumonia. Thrombocytopenia is a very rare adverse effect of telavancin and few studies have evaluated its significance. This report presents such a case associated with telavancin use from the clinical practice of authors.
A 68-year-old female was admitted to hospital due to shortness of breath. She was found to have bilateral pulmonary infiltrate with questionable CHF and pneumonia/pneumonitis and consequent acute hypoxemic respiratory failure. She was hypoxic, requiring 100 percent non-rebreather mask, and had a history of heavy tobacco abuse of smoking about 60 packs a year. Her past medical history was significant for chronic heart failure, type 2 diabetes, hypertension, chronic lymphedema in left lower limb, and breathing disorder. The patient presented with a severe thrombocytopenia of unknown etiology. On admission, the platelet count was 49,000/mm3. The patient had been on telavancin at an outpatient clinic for the past 21 days through her right chest wall tunneled PICC line for a left lower extremity cellulitis. After admission, telavancin was discontinued and replaced by Zosyn in order to empirically treat for pneumonia.
On June 21st, 2016, the patient's platelet count was 49,000/mm3 without signs of bleeding. On June 22nd, 2016, , the platelet count decreased even further to 40,000/mm3.Two days after discontinuing telavancin on June 23rd,the patient's platelet counts improved to 79,000/mm3, and restored to normal levels by the 25th. The improvement in the patient's platelet counts was observed after telavancin was discontinued, and this was seen while the patient remained in critical condition secondary to hypoxemic respiratory failure through the 27th. After resolution of thrombocytopenia, the patient's oxygen needs gradually decreased and the renal function was restored with the serum creatinine of 2.0 mg/dL as her new baseline. After getting transferred to general ward for recovery, she was discharged on July 3rd.

This case report highlights the potential for incidence of thrombocytopenia to occur with prolonged use of telavancin. Although thrombocytopenia is a rare complication of telavancin, it can still occur at an alarming severity, requiring clinical management. Due to its significance, it should be carefully monitored in patients on the drug.

Poster Title: Therapeutic Management of Lower Extremity Arterial Bypass Graft Occlusion: Case Report

Primary Author: Young Park, Georgia Campus - Philadelphia College of Osteopathic Medicine School of Pharmacy, Georgia; **Email:** youngpa@pcom.edu

Additional Author (s):
Dusty Lisi

Purpose: Lower extremity peripheral arterial disease is primarily caused by atherosclerosis and thromboembolic processes that alter the normal functions of the arteries of lower extremities. Surgical revascularization is indicated in patients with limb ischemia without adequate improvement by exercise rehabilitation and pharmacologic therapy and significant limitations of daily activities. Bypass graft occlusion may result due to various reasons such as: technical complication of the graft, thrombosis due to inadequate outflow of blood, myointimal hyperplasia, or progression of atherosclerosis. Intra-arterial thrombolysis is a common method of treatment in lower extremity bypass graft occlusions. Results of a prospective, randomized trial demonstrated that thrombolysis in acutely ischemic (< 14 days) improved limb salvage and reduced the magnitude of the surgical procedure. Studies demonstrated 57% success rate with streptokinase, whereas almost 90% of grafts have been successfully opened with alteplase in other studies. Therapeutic heparin is useful as an adjunct but may increase hemorrhagic complications. If patency of the occlusion is not restored, patient will have to be reassessed for surgical revascularization and possible amputation.

The patient is a 58 year-old male with a history of peripheral vascular disease requiring right popliteal-to-posterior tibial artery bypass two weeks prior to his admission. He presented to an outpatient clinic for evaluation due to complaints of severe right leg pain unable to be controlled by his pain medications. This is an acute change from his previous post-operative state. Patient also complains of tingling in his right foot, in which the duplex ultrasound demonstrated (acute) occlusion of the new right lower extremity (RLE) bypass graft. He was subsequently admitted to a general medical and surgical hospital with 250 beds for repair of the bypass graft. The incision on his right thigh was intact and dry; however, the incision on his calf had mild separation with some sero-sanguineous drainage. Patient was admitted to intensive care unit and initiated on both therapeutic alteplase and heparin infusions.

After two days of continuous therapeutic alteplase and heparin infusions, angiogram was performed and revealed restored patency of patient's bypass graft. The alteplase and heparin infusions were subsequently discontinued. However, following the discontinuation of the alteplase and heparin infusions, the patient developed re-occlusion of his arterial bypass graft. At the same time, the patient became hypotensive with a blood pressure of 78/45 mmHg and was noted to have a myocardial infarction. Electrocardiogram confirmed the presence of ST-segment elevation myocardial infarction which lead to coronary bypass graft (CABG) surgery of four vessels. Due to his overall clinical condition and the risk of bleeding vs. thrombosis following CABG, no further interventions were initiated for the re-occlusion.

About one month following his presentation and management for RLE graft occlusion with alteplase and heparin infusions, the patient developed gangrenes on right toes as well as discharge from some of his leg wounds. The Orthopedics service was consulted for assessment. Based upon the findings of his angiogram, surgery is planned for trans-metatarsal amputation of all five toes on his right foot.

Although there are guidelines available for pharmacologic management peripheral arterial diseases, there is not specific management of peripheral arterial bypass graft occlusion. Current treatments are based on the management of native arteries and regimens used in case reports and small studies. More studies are needed to improve prevention of bypass graft occlusions and management and monitoring after revascularization.

Poster Title: Management of a patient receiving concomitant meropenem and valproic acid therapy

Primary Author: Anastasiya Plagova, Mercer University, Georgia; **Email:** anastasiya.plagova@live.mercer.edu

Additional Author (s):
Melissa Chesson

Purpose: The purpose of this patient case is to describe the management of a patient receiving concomitant therapy with meropenem and valproic acid in a setting of sepsis secondary to a urinary source. The patient was identified on interdisciplinary rounds and the patient information was gathered from the electronic medical record. The patient is a 69 year-old female with a past medical history significant for seizures on anti-epileptic therapy including valproic acid (VPA) and phenytoin, who was admitted to the hospital with new diagnosis of hemolytic-uremic syndrome and who experienced a prolonged complicated hospitalization including acute kidney injury, hospital-acquired pneumonia, Clostridium difficile colitis, and meningoencephalitis. During her hospitalization, the patient also developed severe sepsis secondary to cystitis. To manage the patient's infection, the patient was empirically initiated on meropenem to cover extended-spectrum beta-lactamases and on vancomycin for methicillin-resistant Staphylococcus aureus coverage. Antibiotics were selected based on the patient's complicated hospital course, previous infectious history, previous antibiotic use, and severity of infection. The pharmacist for the service was consulted to assist with antibiotic selection and dosing.

Prior to initiation of meropenem, the patient's VPA level was sub-therapeutic at 32 mcg/mL. The patient's last seizure had been several weeks prior when the VPA had been discontinued, as the patient's seizure history was questionable at the time. The medication had been reinitiated but had not been titrated to therapeutic levels, as the patient had not experienced any additional seizures. The initiation of meropenem resulted in a drop in the VPA level to 11 mcg/mL in 24 hours, however, the patient did not experience any seizures. Subsequently, the VPA dose was titrated from 750 mg orally every 8 hours to 1,250 mg orally every 8 hours. After dose titration, the VPA level was 13 mcg/mL. The patient's VPA level was drawn daily while on therapy and signs and symptoms of seizures were monitored frequently. Meropenem was

continued for 4 days and was eventually discontinued because the cultures grew meropenem-resistant Citrobacter freundii. The patient was started on ceftazidime/avibactam based on culture susceptibilities. After the discontinuation of meropenem, VPA was titrated back down to 750 mg orally every 8 hours and the VPA level increased to 39 mcg/mL.

Literature provides strong evidence for a drug-interaction between VPA and meropenem. Carbapenems may reduce serum VPA to subtherapeutic levels, resulting in loss of seizure control. The onset of this interaction is within 24 hours and the effect can last up to 8 days after discontinuation of the carbapenem. Several studies have evaluated the mechanism of interaction between VPA and carbapenems. Systematically absorbed VPA is glucuronidated by the liver to become valproate glucoronide (VPA-GLU), which is excreted by the kidneys. Researchers have proposed that carbapenems may enhance the rate of glucuronidation of VPA by the liver, hasten the renal clearance of VPA-GLU, or inhibit the bacterial beta-glucoronidase enzyme that hydrolyzes VPA-GLU to valproic acid.

While on concurrent therapy, the serum VPA concentrations should be monitored frequently. Alternative antibacterial therapy may be considered if serum VPA concentrations drop significantly or seizure control deteriorates. However, because of increasingly resistant organisms and the need for broad-spectrum empiric coverage, prescribers often turn to carbapenems. Oftentimes, alternative antibiotic choices are limited, but it is important for the patients to be monitored more frequently. It is also not known whether increasing the VPA dose can overcome this drug interaction. It may be appropriate to use additional anti-epileptic medications while completing carbapenem therapy in patients receiving valproic acid. Thus, it is the role of the pharmacist to monitor for clinically significant drug interactions, including anti-epileptic medications such as VPA, and to make dose adjustments as clinically indicated.

Poster Title: Management of cellulitis utilizing oritavancin to avoid hospital admission

Primary Author: Lauren Lipscomb, Mercer University, Georgia; **Email:** lauren.lipscomb@wellstar.org

Additional Author (s):
Joy Peterson
Tanea Womack

Purpose: Oritavancin is a semi-synthetic, lipoglycopeptide antibiotic indicated for treatment of acute bacterial skin and skin structure infections (ABSSSI) caused by gram-positive microorganisms. A one-time dose of oritavancin 1,200 mg over a three hour infusion time, shows comparable efficacy and safety to seven days of vancomycin when treating ABSSSIs. The purpose of this study is to describe the use of oritavancin in our health system following implementation of a cellulitis pathway utilizing oritavancin in emergency department (ED) and observation status patients to avoid inpatient hospital admission. An evaluation of efficacy, safety, and cost impact of oritavancin use are included.

Methods: This study was approved by the Institutional Review Board (IRB). A retrospective chart review was conducted on patients 18 years and older who presented to a WellStar Health System facility between March 2015 and July 2016 and received oritavancin in the ED, clinical decision unit (CDU), or other units of the hospital using an established pathway designed to avoid inpatient admission. Patients who received oritavancin only in an outpatient infusion center were not included in the study. The primary endpoint was to assess the budget impact of a one-time dose of oritavancin in ABSSSI patients compared to historical data on inpatient hospital admissions for ABSSSI. Secondary endpoints include: admission rate within 30 days of oritavancin administration, adverse events, and clinical cure rate.

Results: Fifty six patients were included in the study. Financial data was included for the initial visit wherein oritavancin was administered, as well as infection-related return visits. Nine patients returned for infection-related reasons within 30 days of oritavancin administration. No significant adverse events were reported. Compared to historical data on inpatient hospital

admissions for cellulitis in patients with minor or moderate diagnosis-related group (DRG) severity, use of oritavancin was associated with a cost savings of $1181.29 per case.

Conclusion: Oritavancin use was found to be safe, effective, and cost saving when used in a clinical pathway to avoid inpatient admission for cellulitis.

Poster Title: Evaluation of the use of IV builder technology in the ordering of intravenous medications for the treatment of hospitalized patients

Primary Author: Shawn Mercer, Mercer University, Georgia; **Email:** shawn.mercer@live.mercer.edu

Additional Author (s):
Laurie Cavendish
Irene Bemis

Purpose: The use of computerized physician order entry (CPOE) and electronic medical records (EMR) have provided both benefits and challenges with regards to medication order entry. The EMR used at Grady Health System (GHS) allows providers and pharmacists to create patient-specific custom intravenous (IV) medication orders using a tool called the "IV builder". This tool is used to order an IV admixture of a non-formulary medication or a custom admixture that is not pre-built in the EMR system. This study was conducted to determine the appropriateness of orders entered using this tool.

Methods: This was a retrospective chart review of 90 patients with at least one medication order placed using the IV builder tool between April 1, 2015 and March 31, 2016. Additionally, a voluntary, anonymous eight question survey was administered to pharmacists, attending physicians, advanced practice providers, and intern/resident physicians to gauge comfort level and knowledge of the IV builder tool. The primary objective of the study was to determine the prevalence of orders using the IV builder tool which were deemed appropriate. Appropriateness was defined as orders including a non-formulary medication and/or an admixture not available as a pre-built order, in addition to medication doses meeting GHS dosing guidelines (when applicable) and admixtures without drug-drug or drug-diluent incompatibilities. Secondary objectives included determining the prevalence of IV builder tool use by various services of the hospital, determining which disciplines use the IV builder tool most often, and evaluating provider and pharmacist comfort and knowledge when using the IV builder tool.

Results: Of the 90 orders that were reviewed, 27 percent (n=25) of the orders were deemed appropriate based on the pre-defined criteria. The top three services utilizing the IV builder tool were internal medicine (62 percent), neurology (15 percent), and surgery (9 percent). The disciplines that used the IV builder tool the most were resident/intern physicians (70 percent) and advanced practice providers (11 percent). The survey was completed by 57 providers and pharmacists. Approximately 35 percent (n=20) of the respondents reported that they had never used the IV builder tool. Of the respondents who reported using the tool (n=37), 35 percent reported using it on a weekly basis and 54 percent reported using it on a monthly basis. When asked about their level of interest in additional training on the IV builder tool, 25 percent of respondents reported not being interested, 56 percent were moderately interested, and 19 percent were extremely interested. When asked how well respondents thought order entry errors, including improper doses and incompatibilities, are caught and prevented by the IV builder tool, only 16 percent of respondents were aware that the IV builder tool does not catch these errors.

Conclusion: A substantial percentage of orders entered using the IV builder tool were not deemed appropriate based the criteria applied. More education for practitioners on appropriate use of the IV builder tool and availability of pre-built orders may be beneficial. Educational efforts may initially be focused on the service that was found to use the tool most often, which was the internal medicine service. The majority of survey respondents indicated that they were open to additional education.

Poster Title: Characterization of copper deficiency in adult patients with a history of major gastrointestinal surgery

Primary Author: Vinh Trang, Mercer University, Georgia; **Email:** vinh.trang@live.mercer.edu

Additional Author (s):
Sarah Cullen
Vivian Zhao

Purpose: Copper is an essential trace element that plays an important role in many human body functions, including mitochondrial respiratory chain, iron absorption, collagen synthesis, neuropeptide and neurotransmitter synthesis, protection from oxidative stress, as well as immune function. Copper is primarily absorbed in the duodenum, thus copper deficiency has been reported in patients with a history of bariatric surgery which copper absorption site is bypassed. The purpose of this study is to further evaluate potential risk factors, signs and symptoms associated with copper deficiency in patients with a history of major gastrointestinal surgery such as gastric bypass, gastrectomy, or Whipple procedure.

Methods: Retrospective chart review was performed for patients who had at least one low serum copper level (men less than 70 mcg/dL; women less than 80 mcg/dL) during the period of January 1, 2004 through June 30, 2016. Enrolled patients were at least 18 years old and had one or more of the following procedures: gastric bypass, partial or total gastrectomy, or Whipple. Patients with a history of Wilson's disease were excluded from the study. Data collection included demographics, past medical and surgical histories, physical findings, and hematological laboratory tests. Descriptive statistics were used to describe the patient population with copper deficiency within the Emory healthcare system. Multivariable analysis was used to characterize risk factors for copper deficiency.

Results: Sixty-nine patients were included in the data analysis, of which 91 percent were female. The average age and body mass index were 50 years and 26.8 kg/m2, respectively. Majority of the patients (90 percent) were on oral diet, nine percent were on home parenteral nutrition, and four percent were on enteral nutrition prior to admission. Forty-six percent of patients had a history of Roux-en-Y gastric bypass, other bariatric surgery (30 percent),

gastrectomy (19 percent), and Whipple (3 percent). The most common co-morbidities were history of anemia (86 percent), gastrointestinal diseases (62 percent), neurological problems (54 percent), hypertension (46 percent), and history of malnutrition (41 percent). Seventy percent of patients were taking an acid reducing medication within a year prior to the low copper level. Most commonly reported manifestations included hypothermia (temperature less than 36 degrees Celsius, 86 percent), weakness or fatigue (86 percent), tachycardia (heart rate greater than 100 beats per minute, 64 percent), hypotension (blood pressure less than 90/60 mmHg, 51 percent), unequal extremity movements (41 percent), and history of falls (29 percent). Notable hematological abnormalities included anemia (30 percent macrocytic, 67 percent normocytic, and 3 percent microcytic), thrombocytopenia, and leukopenia (83 percent, 33 percent, and 14 percent, respectively).

Conclusion: Knowing the signs and symptoms associated with copper deficiency in adult patients with a history of major gastrointestinal surgery can be helpful in the differential diagnosis and allows for faster recognition and treatment. In our study, patients with copper deficiency and a history of gastrointestinal surgery commonly present with hypothermia, weakness or fatigue, tachycardia, anemia, and thrombocytopenia. All these signs and symptoms associated with copper deficiency are not specific; therefore, a greater effort for screening this patient population is warranted.

Poster Title: Evaluation of the utilization and discontinuation of stress ulcer prophylaxis with proton pump inhibitors in critically ill patients at a community teaching hospital

Primary Author: Jonathan Cobb, Mercer University College of Pharmacy, Georgia; **Email:** jonathan.cobb@live.mercer.edu

Additional Author (s):
Brittany White

Purpose: Proton-pump inhibitors are widely used in the inpatient setting to decrease the risk of stress-related mucosal disease in critically ill patients. These agents often fail to be discontinued once patients no longer meet criteria for utilization of stress ulcer prophylaxis. Use of proton pump inhibitors is associated with significant adverse effects including Clostridium difficile infection and pneumonia, highlighting the importance of ensuring appropriate prescribing of these agents. The purpose of this study was to assess appropriateness of inpatient prescribing and discontinuation of proton pump inhibitors in critically ill patients at an academic medical center.

Methods: This study involved a retrospective medication use evaluation of one hundred critically ill patients receiving pantoprazole or esomeprazole between January 2014 and June 2014. Drug codes assigned by the institution were used to identify patients receiving a proton pump inhibitor in an intensive care unit during the study period. Patients were evaluated for drug indications, dosing and frequency of adverse events.

Results: Of one hundred intensive care unit patients receiving a proton pump inhibitor for stress ulcer prophylaxis, eighty-two had an appropriate indication. All patients were initiated on the appropriate dose upon initiation of acid suppression therapy. Upon transfer from the intensive care unit to a floor unit, fifty-five patients received continued stress ulcer prophylaxis without a documented approved indication. Thirty-six patients were discharged on acid suppression therapy without an appropriate indication. Five patients experienced adverse events during therapy (Clostridium difficile).

Conclusion: The results of this study demonstrate inappropriate utilization of stress ulcer prophylaxis in critically ill patients at our facility. As a result of these findings, the clinical pharmacy staff now provides periodic physician education on appropriate use and discontinuation of stress ulcer prophylaxis. The existing intensive care unit transfer order set was amended to include discontinuation of stress ulcer prophylaxis where indicated. These results have also led to development of a hospital policy allowing discontinuation of stress ulcer prophylaxis by a clinical pharmacist for patients who do not meet approved criteria for use.

Poster Title: Efficacy of amlodipine in the treatment of infantile pulmonary hypertension.

Primary Author: Brittany Onyeji, Mercer University College of Pharmacy, Georgia; **Email:** 10620047@live.mercer.edu

Additional Author (s):
Laura Hagan

Purpose: Patient AB is a Caucasian, former 25 week male with a birth weight of 1.025kg, who presented at 3.5 months of age with hypertension (blood pressures in 130s/60s). Past medical history is significant for prematurity, extremely low birth weight, significant chronic lung disease, hypothyroidism, cholestasis, feeding intolerance (status post gastrostomy tube fundoplication), and multiple episodes of pneumonia. At the time of presentation, patient AB was requiring a 7 liter cannula with an increasing oxygen requirement of 29%. Pulmonary hypertension was suspected and confirmed by echocardiogram. Pharmacy was consulted to dose amlodipine. Amlodipine is currently not approved by the Food and Drug Administration for the treatment of hypertension in patients less than six years of age and there is little primary literature data for dosing in patients less than one year of age. After review of the limited primary literature data, a dose of 0.1 mg/kg by mouth daily of amlodipine was chosen. Cardiology was consulted and agreed with medication selection and dose. We expected a significant decrease in systolic blood pressure would be observed in 6-14 days which was calculated using a half-life of 30-60 hours. The patient was monitored daily for adverse effects which included flushing, hypotension, edema, and increased fatigue. Within 48 hours of administration, the patient's blood pressure decreased from 139/66 to 103/62. The patient displayed no adverse effects at that time. By day six on amlodipine, the patient's blood pressure was 93/46. The patient's breathing improved as well which allowed the weaning of supplemental oxygen to a 0.5 liter nasal cannula. The patient continued to exhibit no signs of adverse effects. An increase in blood pressure to 128/68 was noted on day ten. As a result, the patient's dose was increased from 0.1 mg/kg to 0.15 mg/kg by mouth daily and adjusted to account for weight gain. The patient's blood pressure decreased to 90/68 with the new dose. Similar blood pressures were observed over the next three days with no signs of adverse effects. By day 14, the patient again experienced a gradual increase of blood pressure potentially due to weight gain and a relative decreased dose per weight. As a result, amlodipine

was increased to 0.2 mg/kg by mouth daily and spironolactone/hydrochlorothiazide 1 mg/kg by mouth twice a day was added to manage chronic lung disease and hypertension. Soon following the amlodipine dose change and the addition of a second medication, the patient was discharged home on amlodipine 0.2 mg/kg by mouth once daily and spironolactone/hydrochlorothiazide 1 mg/kg by mouth twice a day with a follow-up scheduled with outpatient cardiology. As this report suggests, amlodipine appears to be effective in the treatment of pulmonary hypertension in infants under the age of one with little to no adverse effects. More studies will need to be performed to validate this single case, but it is important to note an experience of safety and efficacy in this understudied population.

Poster Title: Use of an acetaminophen maximum daily dose calculator to prevent unintended acetaminophen overdose in hospitalized patients

Primary Author: Samantha Giroux, Mercer University College of Pharmacy, Georgia; **Email:** samlgiroux@gmail.com

Additional Author (s):
Collin Lee

Purpose: Acetaminophen is a common ingredient in combination pain medications administered to hospitalized patients. To prevent liver toxicity, the FDA recommends no more than 4 grams of acetaminophen be taken in a 24 hour period. Manufacturers of acetaminophen recommend no more than 3 grams within 24 hours. With the abundance of acetaminophen containing products, it is easy to unintentionally administer too much acetaminophen. In response to this risk, Emory Healthcare developed an alert which can notify a nurse when a dose of acetaminophen would exceed 3 grams per day. This project was designed to assess the effectiveness of this alert.

Methods: A computerized rule was developed which allows for the addition of a rolling 24 hour acetaminophen dose across multiple acetaminophen-containing products and routes of administration. As a test of change, the alert was activated in the "background" at Emory University Hospital and data collected over a 48 hour period to capture any patient who would have had the nursing alert fire. A retrospective chart review was performed on these patients to determine the maximum acetaminophen dose administered in the previous 24 hours, the specific acetaminophen products orders, timing of the doses in relation to the alert firing, whether or not the orders were placed as part of a power plan, and whether or not the patient had any liver dysfunction during their stay. Based on the results, changes to standing power plans were implemented and the report was repeated to determine effectiveness of the changes.

Results: A total of 48 patients had the alert fire during the initial 48-hour study window. Forty-seven of the patients on the report had received more than 3 grams of acetaminophen in the previous 24 hours. Twenty-eight patients' acetaminophen orders originated outside of a power

plan and nineteen were ordered as part of a power plan. The average acetaminophen dose for orders outside of power plans was 3.5 grams (highest dose = 4.5 grams). The average acetaminophen dose given within a power plan was 3.9 (highest dose = 7.1 grams). One patient was found to have mild liver dysfunction. Seventy-two percent of patients who received > 3 grams of acetaminophen received it from a single around-the-clock acetaminophen dosage form. The majority of patients would not have exceeded the 3 gram maximum dose if the nurse would have waited an additional 15-20 minutes before giving the dose. The most common power plans containing acetaminophen orders which put patients at risk for > 3 grams in 24 hours were related to Neurology. When the alert was re-run after changes were made to the power plans, only one patient was identified on the report as exceeding the 3 grams daily dose.

Conclusion: The alert, in combination with changes made to power plans and the alert cutoff, proved to be an effective method of identifying patients who would be at the highest risk for receiving more than 3 grams of acetaminophen within a 24 hour period. This alert will result in improved patient safety within our healthcare system.

Poster Title: Face the factors: Evaluating clinical use of coagulation factor VIIa (recombinant) in a pediatric hospital

Primary Author: Heather Corbo, Mercer University College of Pharmacy, Georgia; **Email:** heather.corbo@live.mercer.edu

Additional Author (s):
Helen Giannopoulos
Jennifer Sterner-Allison

Purpose: Children's Healthcare of Atlanta (CHOA) pharmacy department took over dispensing of factors in November 2015. Currently, coagulation factor VIIa (recombinant) is FDA approved for the following indications: Hemophilia A or B, congenital factor VII deficiency, and Glanzmann's thromboasthenia. There has also been literature to support the use of coagulation factor VIIa (recombinant) in treatment of excessive bleeding after cardiac surgery and prophylactically if bleeding was a risk for complication of a cardiac surgery. The objective of this MUE is to assess the usage of coagulation factor VIIa (recombinant).

Methods: A retrospective chart review of patients receiving coagulation factor VIIa (recombinant) at CHOA was conducted from December 2015 to May 2016. Data collection included patient demographics, admission date and diagnosis, physician service, prescribing physician, indication for use, side effects, labs, and use of concurrent blood products. The dose and date of administration was recorded and dosing was assessed for appropriateness based on FDA recommendations and previous clinical trials.

Results: A total of 40 patients received coagulation factor VIIa (recombinant) during the time period of December 2015 to May 2016 and all patients were evaluated. Eighty-five percent of patients were at the Egleston campus and 15% of patients were at the Scottish Rite campus. This is most likely because cardiac procedures take place only at Egleston. Forty-five percent of all patients received coagulation factor VIIa (recombinant) for post-operative bleeding after cardiac surgery. Coagulation factor VIIa (recombinant) was given to 10% of all patients as a rescue intervention, which was defined as any patient that received multiple blood products (platelet concentrate, pRBC, fresh frozen plasma, and/or cryoprecipitate) prior to receiving

coagulation factor VIIa (recombinant). Most of these rescue interventions were cardiac related surgeries and the coagulation factor VIIa (recombinant) was given in the OR. The most common FDA approved uses of coagulation factor VIIa (recombinant) were Factor VII deficiency (12.5% of all patients) and Glanzmann's thromboasthenia (10% of all patients).

Conclusion: The majority of coagulation factor VIIa (recombinant) was used in cardiothoracic surgery. Education and procedure changes will be implemented through collaboration between the cardiothoracic surgeons and the pharmacy department. Protocols will be developed for use of coagulation factor VIIa (recombinant). Some examples of future protocols include coagulation factor VIIa (recombinant) use in cardiac procedures, rescue interventions and post-operative bleeds. A flowchart will be created to assist healthcare professionals in appropriately dosing coagulation factor VIIa (recombinant).

Poster Title: Incidence of hypoglycemia among emergency department patients treated with regular insulin from a hyperkalemia protocol

Primary Author: Hannah Chan, Mercer University College of Pharmacy, Georgia; **Email:** hannah.lee48@gmail.com

Additional Author (s):
Bobby Jacob
Angela Shogbon
Dora Niculas
Brent Allen

Purpose: Hyperkalemia is a common condition found among patients seen in emergency departments and can be fatal if left untreated. The purpose of this study is to determine the incidence of hypoglycemia among patients treated with regular insulin as part of an emergency department hyperkalemia protocol at a large community hospital. Findings from the study will be used to evaluate the emergency department hyperkalemia protocol.

Methods: This was retrospective, observational, pilot study involving electronic medical chart review. Adult patients seen in the emergency department from January 2016 through March 2016 who received treatment with regular insulin from the hyperkalemia protocol were eligible for inclusion in the study. Patients were identified by running a report from the pharmacy system of all patients during this time period who received regular insulin resulting from an emergency physician order from the hyperkalemia protocol order set. The primary endpoint of this study was incidence of hypoglycemia, which was defined as blood glucose less than 70 mg/dL. In addition, severe hypoglycemia was defined as blood glucose less than 40 mg/dL. Additional data collection parameters included demographics, past medical history, admission laboratories, hyperkalemia treatments, post-treatment laboratories, hospital admission, and re-admission. Specific laboratories that were evaluated included including serum blood glucose, point of care blood glucose, serum creatinine, creatinine clearance, potassium, and magnesium. Descriptive statistics were used to summarize the data.

Results: A total of 103 patients were included in the analysis. The average age of patients in the study was 62.9 years with 53 percent being male. Twenty-nine percent of the patients had a previous admission for hyperkalemia and 10 percent of the patients had been admitted previously for hypoglycemia. Additionally, 49 percent of patients had a past medical history of diabetes and 53 percent had end-stage-renal-disease with hemodialysis. The average admission serum blood glucose was 146 mg/dL and the average admission serum potassium was 6.25 mEq/L. Approximately 70 percent of patients received the recommended dose of 10 units regular insulin for treatment of hyperkalemia. A total of 94 number of patients were admitted to the hospital (91.3 percent). The incidence of hypoglycemia among patients treated with regular insulin from the hyperkalemia treatment protocol was 15 percent (n equals 15). In addition, the incidence of severe hypoglycemia was 6 percent (n equals 6).

Conclusion: Findings from this pilot study demonstrate a clinically significant incidence of hyperkalemia in this community hospital setting. This study adds to the limited published literature on this topic. This data warrants extension of the study duration to confirm the incidence of hypoglycemia associated with regular insulin treatment. Furthermore, it is warranted to evaluate the association between risk of hypoglycemia and admission weight, glycemic control, and renal function.

Poster Title: Management of a patient with daptomycin and statin induced rhabdomyolysis

Primary Author: Lisa Sagardia, Mercer University College of Pharmacy, Georgia; **Email:** lisa.michelle.sagardia@live.mercer.edu

Additional Author (s):
Melissa Chesson

Purpose: Rhabdomyolysis is a rapid breakdown of muscle tissue that leads to a release of muscle fiber contents into the bloodstream. The condition is characterized by mild to severe pain typically presenting in the large muscle areas of the lower extremities and is an adverse event associated with daptomycin and statin therapy. Complications of rhabdomyolysis include fluid and electrolyte abnormalities, acute kidney injury, compartment syndrome, and disseminated intravascular coagulation. While rhabdomyolysis is a documented rare side effect of daptomycin therapy, the continuation of concurrent statin therapy is controversial as there are limited case reports documenting the increased risks of rhabdomyolysis with combination therapy. This case report focuses on the treatment of a patient diagnosed with rhabdomyolysis following therapy with daptomycin and a high intensity statin.

A 74 year old African American female with a past medical history significant for dyslipidemia, stroke, and Enterococcus faecalis infective endocarditis presented to the emergency department with increased weakness, fatigue, and dark urine. Laboratory results revealed a serum creatinine (SCr) of 2.11 mg/dL, which was elevated from the patient's baseline of 1.05 mg/dL, abnormal liver function tests, and a significant creatine phosphokinase (CPK) level of greater than 41,000 units/L. Three weeks prior to the presentation to the emergency department, the patient was initiated on atorvastatin 40mg orally daily for secondary stroke prevention and intravenous vancomycin and gentamicin therapy for endocarditis. The choice of antibiotics for the infective endocarditis was based on the patient's history of a true penicillin allergy, despite pansensitive cultures. Within two weeks of initiation of vancomycin and gentamicin therapy, the patient developed acute kidney injury as evidenced by an elevated SCr of 2.60 mg/dL and a calculated creatinine clearance (CrCl) of 21.9 mL/min. The patient was then transitioned to intravenous daptomycin 10 mg/kg/day. The change in antibiotics occurred at her rehabilitation center without a pharmacy consult and no dose adjustments were made to account for her renal impairment. Based on the severity of the patient's renal injury, the most

appropriate daptomycin dosing interval would have been every 48 hours. Statin therapy was also continued based on her recent stroke history despite cautionary labeling in the antibiotic's package insert to consider the suspension of statin therapy. Ten days after daptomycin initiation, the patient presented with rhabdomyolysis.

The patient was admitted to the hospital and was treated with aggressive fluid resuscitation and a change in antibiotic therapy. Daptomycin and atorvastatin therapy were discontinued immediately as this was determined to be the etiology of the patient's rhabdomyolysis. The patient was maintained on 3-6 liters of intravenous normal saline per day for the treatment of rhabdomyolysis and was initiated on an intermittent dosing regimen of vancomycin for completion of her endocarditis treatment. Monitoring parameters included daily renal and liver function tests, urine output, electrolytes, fluid status, and morning vancomycin levels with a goal to re-dose the patient if the level was less than 20 mg/L. Overall, the treatment of this patient with aggressive fluid resuscitation was successful. The goal urine output was achieved within the first two days of treatment, renal and liver function tests improved, CPK levels decreased dramatically to 735 units/L by the day of discharge, and there were no complications associated with fluid overload or electrolyte imbalances.

This case study emphasizes the importance of proper dosing of daptomycin in renal impairment, the risks associated with the co-administration of statin therapy and daptomycin, and the treatment of rhabdomyolysis. Pharmacists can play an integral role in patient care by assisting in the appropriate selection and dosing of antimicrobials, especially in complicated patient cases and by evaluating the safe use of concurrent medications.

Poster Title: Evaluation of Respiratory Therapist Treatment Protocol (RTTP) in Critically Ill Patients on Mechanical Ventilation at a Large Academic institution

Primary Author: Julianna Cebollero, Mercer University College of Pharmacy, Georgia; **Email:** julianna.cebollero@gmail.com

Additional Author (s):
Dr. Marina Rabinovich

Purpose: Bronchodilators are used in mechanically ventilated (MV) patients with asthma and chronic obstructive pulmonary disease (COPD). At Grady Health System, orders for bronchodilators are written based on the respiratory therapy treatment protocol (RTTP). In the respiratory therapist (RT)-driven RTTP, the RT initiates treatments based on an acuity score, ranging from 0 to 4, using patient characteristics such as pulmonary history and chest x-rays. The American Association for Respiratory Care (AARC) estimated about 30-60% of inpatient respiratory care is inappropriate. Previous studies have evaluated the benefits of RT-driven protocols in non-ICU patients, however, data for critically ill ICU patients are lacking.

Methods: The primary objective was to evaluate adherence to RTTP and bronchodilator therapy with albuterol and ipratropium in MV patients admitted to SICU and MICU at Grady Health Systems. Secondary objectives included the assessment of bronchodilator therapy before and after RTTP, duration of drug therapy and mechanical ventilation, and the incidence of hypokalemia and ventilator-associated pneumonia (VAP) associated with the use of nebulized bronchodilator therapy. Adherence is defined as an order submitted by an RT, acuity score documented on the medical record, and metered dose inhaler (MDI) use for MV patients. Non-adherence to the RTTP was defined as lack of acuity score documentation, wrong frequency, or given nebulizers during ventilation. IRB-approved, retrospective electronic medical record review of a target sample size of 200 patients, 30 adult patients thus far, who received bronchodilator therapy while on mechanical ventilation for >24 hours between January 2011 and December 2015. The pre-protocol phase included patients from January 2011 to December 2012 and the post-protocol phase included patients from January 2013 to December 2015. Inclusion criteria were critically ill patients in the medicine (MICU) or surgical (SICU) intensive care units on mechanical ventilation >24 hours and on bronchodilator therapy

with albuterol and/or ipratropium nebulizer and/ or MDI. Exclusion criteria included non-ICU patients, < 24hrs of ventilation, pediatric, pregnant women, prisoners, intellectually or emotionally impaired, institutionalized, or physically handicapped patients.

Results: 30 randomly selected patients were evaluated thus far, before (n=11) and after (n=19) RTTP. The sample consisted of 50% male, median age 59 years, and 90% in MICU. The most common admission diagnoses were pulmonary, mainly due to COPD, (40%) and cardiac (23%). Before RTTP, 91% of orders were entered by a physician and 63% of MV patients received MDI bronchodilators. Post-RTTP, adherence to the protocol occurred in 53% (n=19) of all patients with 79% orders entered by an RT, documented an acuity score, and received MDI bronchodilators during MV. Non-adherence to the RTTP was due to failure of acuity score documentation (33%), wrong frequency of bronchodilators (33%), or given nebulizers during ventilation (22%). Median duration of mechanical ventilation was 7 days and 10 days, before and after protocol, respectively. Median duration of bronchodilator therapy was 3 days and 6 days, before and after protocol, respectively. Patients without obstructive lung disease who received bronchodilator therapy reduced from 72.7% before protocol implementation to 63.2% after protocol. Incidence of hypokalemia and VAP were 10% and 7%, respectively.

Conclusion: The RTTP allows for standardization of therapy in MV patients based on a set of criteria, leading to a streamlined therapy. Prior to RTTP, orders were entered by physicians and more MV patients received nebulized therapy. However, after RTTP, orders were entered by RTs and the use of nebulizer use was diminished. Two VAP events occurred (one before and one after RTTP) in patients who received nebulized bronchodilator therapy. Protocol driven therapy is an innovative approach that hospitals can take to address the inadequacies, inefficiencies, and wastefulness.

Poster Title: Management of invasive Scopulariopsis infection in an immunocompetent patient with a bio-prosthetic aortic valve

Primary Author: Shedrick Martin, Mercer University College of Pharmacy, Georgia; **Email:** shedrick.martin@live.mercer.edu

Additional Author (s):
Melissa Chesson

Purpose: Scopulariopsis is a common mold found in many indoor environments. It rarely infects people beyond simple onychomycosis and is not known to be a highly invasive organism. Scopulariopsis typically does not have the ability to invade tissues or cause bacteremia. In the few cases of invasive deep tissue infections reported in the literature, the mold was found to be highly resistant to anti-fungal therapies such as amphotericin B, posaconazole, voriconazole, and micafungin which are all common agents used in the treatment of serious fungal infections. There is limited information available regarding the treatment of invasive infections caused by this organism in immunocompetent individuals and no evidence in using isavuconazole in the treatment of Scopulariopsis infections in any patient. The purpose of this case study is to describe the use of isavuconazole in the treatment of an aortic root infection caused by Scopulariopsis.

The patient is a 69-year-old female with a bio-prosthetic aortic valve that was admitted to the emergency department following three days of left hand weakness, left leg claudication, and persistent headache. Magnetic resonance imaging of the head revealed multiple embolic events in bilateral hemispheres of the brain. She was also found to have a thrombus in the brachiocephalic artery and right internal carotid artery stenosis. Transesophageal echocardiogram of the chest revealed a mobile mass on the aortic root. As a result, the patient continued to have new embolic infarcts in the right hemisphere during the early part of her hospital stay which was attributed to the mass. The mass was excised and tissue cultures resulted with preliminary fungal growth while blood cultures remained negative for any growth. Apparent risk factors leading to the infection could not be established and the infectious disease team was consulted for treatment recommendations. The patient was initiated on empiric therapy with intravenous micafungin and intravenous isavuconazole to broadly cover infection while awaiting fungal identification. Antibiotics were then de-escalated to oral

isavuconazole 372 mg daily as monotherapy after microbiology lab results isolated Scopulariopsis. Scopulariopsis was not identified to the species level due to difficulty in differentiating between the 30 species of the organism. Such determination requires a laborious biochemical process and specific morphological criteria which was deemed not beneficial by the lab. The patient's stay was complicated by thrombocytopenia following initiation of heparin. After ruling out heparin induced thrombocytopenia, the pharmacy team immediately managed anticoagulation for optimal treatment and continued to follow. The infectious disease team recommended monitoring liver enzymes while on long-term triazole therapy. At discharge the patient did not display any further signs of infection and was to complete 6 months of therapy with oral isavuconazole 372 mg daily. The patient was discharged to a rehabilitation center due to left body weakness resulting from the multiple emboli. At the patient's 4 week post-discharge infectious disease appointment, the patient continued to improve on drug therapy with no additional complications.

The use of anti-fungal agents for the treatment of rare and highly resistant infections require great vigilance in monitoring for side effects and appropriate response. The treatment plan for this patient was complicated and involved the off-label use of a new medication emphasizing the role of careful monitoring in rare disease state management. Monitoring the effectiveness and safety of drugs not proven to have treatment effectiveness or safety data beyond what is indicated is important to manage patients adequately. If proven safe and effective, isavuconazole could represent a potential treatment option for infections secondary to Scopulariopsis species.

Poster Title: Outcomes in patients with acute ischemic stroke presenting with low National Institute of Health Stroke Scale (NIHSS) scores or rapidly improving symptoms

Primary Author: Summer Warnken, Mercer University College of Pharmacy, Georgia; **Email:** summer.warnken@live.mercer.edu

Additional Author (s):
Matthew McAllister
Kelli Brennan

Purpose: Alteplase has traditionally not been offered to patients with acute ischemic stroke presenting with low National Institute of Health Stroke Scale (NIHSS) scores or rapidly improving symptoms due to the perception that the risk of treatment may outweigh the potential benefits. The purpose of this study was to determine the rate of favorable outcomes upon discharge for patients presenting with low NIHSS scores or rapid clinical improvement who did not receive alteplase treatment as compare with those who did.

Methods: We conducted an institutional review board approved single-center, retrospective electronic chart review of all patients presenting to the emergency department with an acute ischemic stroke between July 2014 to September 2016. Patients were included if they were at least 18 years old, presented to the emergency department within 4.5 hours of symptom onset, and had an initial NIHSS score of less than 4 or demonstrated rapid improvement of their stroke symptoms prior to the administration of alteplase. Patients were identified by accessing the American Heart Association's "Get with the Guidelines – Stroke Database" for all patients presenting to Midtown Medical Center with acute ischemic stroke during this timeframe. Data collected for both groups included patient demographics, past medical history, hospital length of stay, neuroimaging including non-contrast head CT, head CT-angiogram, brain magnetic resonance imaging, and brain magnetic resonance angiogram; and the modified Rankin Score upon discharge. The primary outcome was the percentage of patients with favorable outcome (modified Rankin score 0 to 1, favorable, or 2 to 6, unfavorable) of those patients who received alteplase and those who did not. Secondary outcomes included disability and final discharge disposition (discharged to home, long-term care facility, etc.) of patients.

Results: A total of 51 patients were included, 24 received alteplase and 27 did not receive alteplase. Two patients demonstrated rapid clinical improvement in the alteplase group and 24 in the non-alteplase group. Upon discharge, 62.5 percent of alteplase patients and 44.4 percent of non-alteplase patients had favorable modified Rankin Scale scores of 1 or less, P 0.197. There were no deaths reported. A total of 41.7 percent of alteplase patients and 55.6 percent of non-alteplase patients were discharged with disabilities requiring the use of assistive devices. Of these patients, 8.3 percent of the alteplase group required placement in an acute rehabilitation facility and 18.5 percent of the non-alteplase group required placement in either an acute rehabilitation facility or in a skilled nursing facility, P 0.425.

Conclusion: The results of this study did not demonstrate a significant difference in the level of disability upon discharge of patients presenting with low NIHSS scores or rapid improvement who did not receive alteplase treatment as compared to those who did. A higher percentage of patients who received alteplase were discharged with a more favorable modified Rankin Score than those who did not receive alteplase; however, these results were not statistically significant. There was no significant difference in disability or discharge disposition between the two groups upon discharge. Larger studies are needed to confirm these results.

Poster Title: Evaluation of Time to Antibiotic Administration for Patients presenting with Febrile Neutropenia

Primary Author: Catherine Akin, Mercer University College of Pharmacy, Georgia; **Email:** catherine.akin@live.mercer.edu

Additional Author (s):
Marjorie Adams Curry
Jennifer LaFollette
Saira Rab
Jordan Wong

Purpose: Febrile neutropenia (FN) is an oncologic emergency associated with significant morbidity and mortality. Although the Infectious Disease Society of America guidelines recommend antibiotic initiation within 2 hours of presentation, there is a paucity of data supporting antibiotic timing and the impact on patient outcomes. Data supporting the impact of empiric antibiotic timing, causative organisms and adherence to guidelines may lead to improvement in the management of this oncologic emergency. The purpose of this study was to determine the impact of empiric antibiotic initiation within 2 hours of presentation on adverse outcomes in patients presenting with FN at Grady Health System.

Methods: An IRB-approved retrospective chart review analyzed patients diagnosed with FN in the inpatient setting and emergency department (ED) between May 2013 and May 2016. Patients were included in the study if a febrile episode (temperature greater or equal to 38.0 degrees Celsius) occurred concurrently with an absolute neutrophil count (ANC) less than 500 cell/mm3. Subsequent FN episodes during the same admission or patients on therapeutic antibiotics at time of fever onset were excluded. Times of fever onset, admission, and first empiric antibiotic dose were collected. Additionally, empiric antibiotics, antibiotic doses, and resulted bacterial cultures were collected. The primary objective of this study was to determine the impact of empiric antibiotic initiation within 2 hours of presentation of FN on adverse outcome, defined as a hospital stay of greater than 2 weeks after the start of the episode, admission to a step-down unit or an ICU, or death during hospitalization. Secondary objectives

included evaluating time to first dose of empiric antibiotics and compliance with the health system's FN protocol.

Results: A total of 1474 incidences of ANC less than 500 cells/mm3 were identified. A random sample of 277 were evaluated, representing 76 patients, and 19 patients with 20 FN episodes met inclusion criteria. Ninety percent of episodes (n=18) had a cancer diagnosis and 10 percent were positive with HIV (n=2). Overall, 70% of episodes included an adverse outcome (n=14). The hospital stay was greater than or equal to 2 weeks for 55 percent of episodes (n=11), 25 percent were admitted to a step-down unit or ICU (n=5), and 5 percent died during hospitalization (n=1). Of the 20 episodes, 5 received empiric antibiotics within 2 hours of presentation of FN. The median time to first dose of empiric antibiotics was 13 hours (range 1.7-53.9). All patients received an anti-pseudomonal beta-lactam empiric antibiotic, consistent with the health system's protocol. An adverse outcome was experienced by 4 of the 5 patients that received antibiotics within 2 hours and by 10 of the 14 patients that received antibiotics after 2 hours. A cultured organism was identified in either blood or urine cultures of 7 patients including Escherichia coli (2), Klebsiella pneumoniae (1) , Enterobacter cloacae (1), Group A streptococcus (1), and Enterococcus faecium (2).

Conclusion: Overall, adverse outcomes in patients receiving antibiotics within 2 hours and after 2 hours of documented fever were comparable, 80 percent and 67 percent, respectively. A larger sample size may help to highlight the difference in adverse outcome rates among patients based on time to empiric antibiotic administration. Compared to other retrospective chart reviews, the patients identified in this study were more likely to have solid tumor malignancies rather than hematologic. Enterobacter cloacae bacteremia and sepsis were the cause of death for the single patient that died. The cultured organisms were consistent with previously reported studies in patients with FN.

Submission Type: Evaluative Study

Session-Board Number: 3-037

Poster Title: Evaluation of empiric urinary tract infection (UTI) guidelines based on a stratified antibiogram in a tertiary community teaching hospital

Primary Author: Winifred Kennebrew, Mercer University College of Pharmacy, Georgia; **Email:** winifred.m.kennebrew@live.mercer.edu

Additional Author (s):
Deanne Tabb
Daniel Cullison

Purpose: Escherichia coli (E. coli) is the most prominent urinary isolate found in urinary tract infection. There are established guidelines for the proposed empiric treatment of uncomplicated and complicated urinary tract infections that cover E. coli. However, E. coli resistance is on the rise. The purpose of this study is to determine if Midtown Medical Center's (MMC) UTI empiric antimicrobial guidelines are appropriate based on a stratified antibiogram of urinary isolates.

Methods: This retrospective study of susceptibility data for urinary isolates was approved by the Institutional Review Board at Mercer University College of Pharmacy. Urinary isolates were collected from June 2015 through July 2016 at Midtown Medical Center. Organisms for inclusion consist of positive urinary cultures with an identified pathogen in inpatients and patients reporting to the Emergency Trauma Center. Duplicate isolates found in a patient in a calendar year were excluded. A stratified antibiogram was developed using susceptibility data from the urinary isolates identified. A comprehensive literature review was performed to define uncomplicated and complicated urinary tract infection and identify updated UTI evidenced based recommendations for antibiotic selection. The institution's empiric guideline for urinary tract infection was assessed based on current literature and the generated antibiogram.

Results: A total of 1653 urinary isolates were evaluated for percent susceptibility to various antibiotics. The most prevalent isolate was E. coli (49.5 percent), followed by Klebsiella pneumoniae (13.2 percent), Enterococcus faecalis (9.7 percent), Proteus mirabilis (6.4 percent), and Pseudomonas aeruginosa (4.8 percent). Oral antibiotics endorsed by IDSA for community acquired UTI include nitrofurantoin, trimethoprim/sulfamethoxazole, and alternatively

fluoroquinolones and beta lactams. Intravenous agents include fluoroquinolones, aztreonam, and ceftriaxone. For complicated UTI with multi-drug resistant (MDR) risk factors, coverage includes intravenous antibiotics with pseudomonal activity. MMC's empiric guidelines for antibiotic selection are consistent with the national guidelines. Primary literature recommends avoiding empiric use of an agent with a resistance rate exceeding 21 percent. E. coli isolates at MMC currently show 31 percent resistance to trimethoprim/ sulfamethoxazole and 28 percent resistance to levofloxacin. However, 97 percent of E. coli strains were susceptible to nitrofurantoin, 89 percent to cefuroxime and 93 percent to ceftriaxone. For Pseudomonal coverage, susceptibility to ceftazidime and piperacillin/tazobactam was 85 percent and 88 percent respectively. In the case of a penicillin or cephalosporin allergy, pseudomonal susceptibility to tobramycin and aztreonam was 89 percent and 59 percent respectively.

Conclusion: After review of the stratified urinary antibiogram and MMC's empiric guidelines, the following recommendations for change were made: add durations of therapy for uncomplicated and complicated UTI, change ceftazidime to piperacillin/tazobactam and delete adjunctive tobramycin for complicated UTI with MDR risk factors, and remove antibiotic selection based on age stratification.

Poster Title: Management of tuberculosis meningoencephalitis in an immunocompetent adult patient

Primary Author: Sera McNutt, Mercer University College of Pharmacy, Georgia; **Email:** sera.mcnutt@gmail.com

Additional Author (s):
Melissa Chesson

Purpose: Infection with tuberculosis is a prevalent global health concern associated with high rates of morbidity and mortality. Tuberculosis infections are more common in developing countries and often present in immunocompromised patients, such as those infected with Human Immunodeficiency Virus (HIV). On occasion, Mycobacterium tuberculosis (MTB) infection involves extra-pulmonary manifestations including infection of the central nervous system (CNS), however, such manifestations are most common in pediatric populations. This case report is an example of an immunocompetent, adult patient with no recent travel history who presents with disseminated tuberculosis meningoencephalitis. A 71 year old female presented to the neurocritical care unit as a transfer from a neighboring hospital where she had presented with altered mental status and recent weight loss. After transfer, she was treated empirically for bacterial, fungal, and viral meningitis. The infectious disease team recommended a polymerase chain reaction (PCR) panel to screen for the presence of multiple bacterial, fungal, and viral pathogens in the cerebrospinal fluid (CSF). The results of the test suggested the presence of Listeria monocytogenes. Consequently, antibiotic therapy was narrowed to monotherapy with intravenous ampicillin, however, the patient's clinical status did not improve on ampicillin therapy and CSF cultures failed to result positive Listeria growth. The patient subsequently developed obstructive hydrocephalus which required the placement of a ventriculoperitoneal shunt. Two weeks after admission, sputum and CSF cultures resulted positive for acid fast bacilli, eventually confirmed through PCR analysis as disseminated tuberculosis with CNS and genitourinary manifestations. Ampicillin therapy was discontinued and the patient was initiated on rifampin, isoniazid, pyrazinamide, and ethambutol (RIPE) therapy along with a 6 week corticosteroid taper which has demonstrated a mortality benefit in MTB CNS infections. Following 2 months of RIPE therapy, the patient is expected to complete 7-

10 months of isoniazid and rifampin therapy. The patient's clinical status improved on RIPE therapy.

There is an important role for pharmacists in assisting with the management and monitoring of patients receiving RIPE and corticosteroid therapy. RIPE and steroid therapy individually, and especially concomitantly, are known to cause lab abnormalities and serious toxicities. In addition to assisting with dose selection, extensive monitoring of organ function and lab values, as well as implementation of supportive therapies for prevention of adverse effects, all require vigilant work from the clinical pharmacy team and provide multiple opportunities for intervention. Rifampin and isoniazid are involved in many drug interactions through induction of hepatic enzymes. This property has the potential to affect serum levels of other medications important for management of this patient including corticosteroids, thyroid supplementation, and anti-emetics. Additionally, prolonged therapy of these medications, for 1 year or more, requires thorough patient education about the importance of medication compliance and associated adverse effects. Adherence to MTB treatment is essential to patient and public health and pharmacists play a key role in ensuring medication acquisition and proper administration. Prolonged therapy means increased likelihood of adverse events and it is the responsibility of the pharmacist to educate the patient on what to expect and how to identify toxicities. This case is an example of the role of a clinical pharmacist in managing seriously ill patients receiving complicated drug therapies that include potentially toxic and highly interactive medications.

Poster Title: Bone fractures with minimal trauma in two patients receiving adalimumab therapy

Primary Author: Aseala Abousaud, Mercer University College of Pharmacy, Georgia; **Email:** aseala.abousaud@live.mercer.edu

Additional Author (s):
Lydia Newsom
David Roberts

Purpose: Adalimumab is a recombinant monoclonal antibody that binds specifically to tumor necrosis factor-alpha (TNF-alpha) and modulates cytokine-mediated inflammatory processes. Adalimumab is currently approved by the Food and Drug Administration for the treatment of multiple disease states including Crohn's disease, ulcerative colitis, rheumatoid arthritis, and psoriatic arthritis. Bone health is a concern for patients diagnosed with many of these disease states due to frequent use of steroid-based therapy and other concomitant risk factors that may predispose the patient to osteopenia or osteoporosis. TNF-alpha itself affects bone turnover by activating osteoclasts and inhibiting osteoblast differentiation, thus increasing bone resorption and decreasing bone formation. Thus, adalimumab therapy may positively impact bone health in patients with underlying inflammatory-mediated disease states. The studies done to examine the impact of TNF-alpha inhibitors on bone health are limited. The purpose of this case report is to present two patients who developed stress fractures with limited trauma while receiving adalimumab therapy. Patient 1 is a 56 year old female with a past medical history of rheumatoid arthritis, type 1 diabetes, hypothyroidism, hypertension, and hyperlipidemia. The patient is receiving adalimumab 40 mg subcutaneously every other week and leflunomide 20 mg by mouth daily for the treatment of rheumatoid arthritis with past therapies including remote glucocorticoid pulse treatment, methotrexate, hydroxychloroquine, and etanercept. The patient tripped off a curb while walking resulting in right proximal leg pain. Magnetic resonance imaging revealed an atypical right femoral stress fracture suggestive of bisphosphonate exposure. However, current bone mineral density findings were within normal limits and the patient denied previous bisphosphonate use. Due to delayed fracture healing with physical therapy and limitation of weight-bearing activity, the patient was instructed to discontinue adalimumab and was prescribed teriparatide 20 mcg subcutaneously daily with improvement in pain and fracture

healing on imaging. Patient 2 is a 68 year old male with past medical history of psoriatic arthritis, psoriasis, osteoarthritis, gout, benign prostatic hyperplasia, and exercise-induced asthma. The patient is receiving adalimumab 40 mg subcutaneously every other week for psoriatic arthritis with previous therapies including azulfidine, sulfasalazine, oxaprozin, and remote glucocorticoid use. The patient sustained an oblique fracture in the distal tibial shaft while he was running as a part of regular exercise. Bone mineral density studies revealed osteopenia with t-scores of -0.9 in left total hip and 1.6 in the lumbar spine; however, post hoc calculation of the 10-year risk of major osteoporotic or hip fracture did not meet thresholds for pharmacotherapy prior to the patient's fracture. This patient was also prescribed teriparatide 20 mcg subcutaneously daily for delayed fracture healing, but continued concomitant adalimumab therapy with subsequent fracture healing after a prolonged treatment course. These two cases of atypical fractures occurring with minimal trauma raise questions about the pathologic impact of adalimumab on bone health and indicate the need for further investigation. The pharmacy team in the internal medicine clinic was consulted by the patients' primary care physician to discuss the potential relationship of adalimumab therapy and fracture occurrence and healing. The pharmacy team played an integral role in providing drug information and clinical research to the multidisciplinary team and patients in addition to providing support for the documentation of these adverse events. As the use of adalimumab and other biologic products will likely expand in the future due to numerous indications and the approval of biosimilar products, pharmacists are primed to promote safe and effective use of these medications by providing current drug information to healthcare providers and patients, appropriately reporting adverse events, and contributing to the medical literature regarding experience with these agents.

Poster Title: Chronic stress increases urinary bilirubin in adolescent rats

Primary Author: Shoshanna Robinson, Mercer University College of Pharmacy, Georgia; **Email:** shoshanna.j.robinson@live.mercer.edu

Additional Author (s):
Sajia Kotwal
Meghan Hibicke
Renee Hayslett

Purpose: Chronic stress is believed to contribute to the progression of type 2 diabetes mellitus (T2DM), non-alcoholic fatty liver disease (NAFLD), and depression. Depressed patients often display elevated cortisol. Chronically elevated cortisol can cause insulin resistance, a characteristic pathology of T2DM, and compensatory generation of free fatty acids and ketones. Fatty acids are converted to triglycerides and LDL in hepatocytes, a characteristic of NAFLD. Urine can contain biomarkers characteristic of these diseases. The purpose of this study is to evaluate urine samples from a putative depression model for biomarkers associated with type T2DM and NAFLD using urinary dipsticks for rapid screening.

Methods: Urine samples were obtained from two previous studies using adolescent chronic restraint stress (aCRS) to model depression in adult female Sprague-Dawley (SD) rats. Urine samples were obtained from acRS rats without treatment, acRS rats that received desipramine as treatment, and non-restrained control rats. Urine was passively collected between 8am to 10 am at the beginning and end of the restraint and treatment periods. Urine samples were transferred from the floor of the chamber by pipet and stored at -80 degrees celsius. Samples were thawed and briefly vortexed to resuspend sediments. 15 microliters of urine was pipetted onto select sections of the Accutest Urine reagent strips (JANT pharmaceutical Corporation, Encino, CA). At 30, 30, 40, and 60 seconds, sections for glucose, bilirubin, ketones, and protein were visually compared to the standards diagram on the test strip package and the associated values were recorded. Data was analyzed using excel to perform t-tests and expressed as the mean plus or minus standard error of the mean (SEM), significance set a priori at P less than 0.05.

Results: aCRS rats displayed significantly greater change in urinary bilirubin vs non-restrained rats after the restraint period (P equals 0.029). aCRS rats that were given desipramine, displayed a downward trend change in urinary bilirubin after the treatment period. No differences were found in protein, ketone, or glucose between treatment groups.

Conclusion: aCRS does not elicit urinary glucose detectable by this rapid screening method, but aCRS rats may be vulnerable to NAFLD. There is evidence of impaired liver function or liver damage in aCRS rats. This data can pose promising preliminary data that can be used to justify looking for NAFLD in depressed patients. This disease state modeled in rats can be useful to evaluate these conditions in humans. Clinical relevance is due to the fact that chronic stress may precipitate metabolic disorders and alter patient outcomes. These results may justify screening depressed patients for liver dysfunction with a convenient urine screening.

Poster Title: Impact of an analgosedation protocol in elderly critically ill trauma patients

Primary Author: Wei Lai, Mercer University College of Pharmacy, Georgia; **Email:** weiwei8236@gmail.com

Additional Author (s):
Vivian Liao
Anne Keddo
Mark Walker
Teresa Pounds

Purpose: Accurate pain and sedation assessments, with appropriate selection and management of analgesic and sedative agents are associated with improved clinical outcomes for mechanically ventilated patients in the intensive care unit (ICU). The purpose of the study is to evaluate a pain, agitation, and delirium (PAD) protocol before and after implementation on the duration of mechanical ventilation in critically ill trauma patients with a focus on patients older than 65 years.

Methods: The study is designed as a pre- and post-, cohort, observational study that assesses outcomes before and after implementation of the PAD protocol. Patients greater than 18 years old requiring mechanical ventilation within 72 hours of ICU admission are included in the study. Additional inclusion criteria include an ICU admission with a diagnosis related to trauma during the pre-protocol implementation period (October 2013 – September 2014) and the post-protocol implementation period (October 2014 – September 2016). Patients will be excluded for the following reasons: concurrently receiving neuromuscular blocking agents, requiring greater than 60% FiO2 on mechanical ventilation, receiving atypical or typical antipsychotic medications prior to hospitalization, recent ICU admission in the previous 2 months, initial Glasgow Coma Scale score less than 12, pregnancy, and documented conditions such as alcohol withdrawal, myocardial infarction, and psychiatry history. The primary objective is to assess the impact of the analgosedation protocol on clinical outcomes in mechanically ventilated ICU patients. The primary outcome is to compare the difference in time on mechanical ventilation pre- and post-protocol implementation among participants and a subgroup analysis comparing the difference between patients 65 years and above and patients below 65 years.

Results: Out of a total of 93 patients, only 17 patients were above 65 years old. The difference in time on mechanical ventilation in pre- and post-protocol implementation groups was 1 day (p = 0.96). The lengths of stay in the hospital and ICU were similar before and after protocol implementation. No difference in mortality was observed. The use of morphine was significantly different after the implementation of the analgosedation protocol (p = 0.0002), but propofol and midazolam use remained similar before and after protocol implementation.

Conclusion: The time on mechanical ventilation, ICU, and hospital length of stay was similar in the pre- and post-protocol implementation groups. Utilization of opioids was higher in the post-implementation group.

Poster Title: Case report of de novo atypical hemolytic uremic syndrome post heart transplant

Primary Author: Sajia Kotwal, Mercer University College of Pharmacy, Georgia; **Email:** sajiakotwal@yahoo.com

Additional Author (s):
Naadede Badger-Plange

Purpose: This case presents the development of atypical Hemolytic Uremic Syndrome (aHUS) in 27-year old patient post heart transplantation. Atypical hemolytic uremic syndrome is a rare, life-threatening genetic disease that can affect vital organs in the body, such as kidneys, heart, or the brain. It is caused by chronic, uncontrolled activation of the complement pathway, leading to the formation of blood clots in small vessels all throughout the body, called systemic thrombotic microangiopathy. Progression to renal failure and end-stage renal disease is also common in patients with untreated aHUS. It is often challenging to diagnose without a family history of the disorder because of very general symptoms often associated with other diseases. In this report, we highlight the case of a deceased, 27-year-old male patient, who presented to Piedmont Atlanta Hospital on May 31st, 2016, with chief complaint of nausea and vomiting for one week. Additionally, he was experiencing fatigue for two weeks prior to hospitalization. The patient has a past medical history of congestive heart failure, atrial fibrillation, and ventricular tachycardia. He was admitted to the Intensive Care Unit (ICU) in Piedmont Atlanta for inotropic support and diuresis. The patient was classified as NYHA Class IV, stage C heart failure with an ejection fraction of 25%, and was listed as status 1A for heart transplant. One month later, he underwent heart transplantation and was placed on Prograf, Cellcept, and Prednisone for immunosuppression therapy. Post-op, the patient developed acute kidney injury, anemia, thrombocytopenia, and neutropenia. As a result, Prograf was held. Additionally, Cellcept and prednisone doses were tapered down, however the patient's condition was deteriorating despite all efforts taken to prevent his worsening condition. The oncology team initially ruled out acute hemolytic uremic syndrome due to the lack of associated clinical or hematologic clues to this etiology. However, when the results of genetic testing were positive for heterozygous mutation and when increased LDH with rare schistocytes was seen on peripheral blood smear, the patient was diagnosed with aHUS. After diagnosis, he received seven days of plasmapheresis and three doses of Soliris. Prior to the initiation of Soliris therapy, the patient

received the meningococcal vaccine and was also given penicillin as prophylaxis during Soliris therapy due to the high risk of meningococcal infections. The patient received Solaris IV 900 mg once a week. The patient's condition appeared to be improved based on impressive progress of CBC and clinical improvement of acute kidney injury. Furthermore, he tolerated being off inotropic support well. However, on the morning of August 31st, 2016, he had a cardiac arrest and developed a profound coagulopathy that was unresponsive to more than 100 units of blood. He received a continuous infusion of blood but still remained severely coagulopathic, anemic, and asystolic on the monitor. A combined decision was made to decelerate care by the primary treatment team and the patient's family. As this case series illustrates, the classic hematologic findings of aHUS appeared late in this case. De novo aHUS is uncommon after transplantation. Due to limited knowledge of the genetics and the etiology of the disease combined with overlapping clinical features associated with other disease states, there is often a delay in the diagnosis and initiation of appropriate treatment of this rare disease.

Poster Title: Evaluation of therapeutic enoxaparin dosing in the obese population

Primary Author: Lacey Boutwell, Mercer University College of Pharmacy, Georgia; **Email:** lacey.boutwell@live.mercer.edu

Additional Author (s):
Lilly Hilding

Purpose: Enoxaparin is a low molecular weight heparin used for acute coronary syndrome, to bridge to a vitamin K antagonist, and to prevent and treat blood clots. Patients at Midtown Medical Center, regardless of body mass index, receive a standard 1 mg per kg treatment dose with frequency adjusted for creatinine clearance. Analyzing anti-Xa values in regard to dose received allows for evaluation of the drug's theoretical effectiveness and if there is potential concern for accumulation. This project was designed to assess dosing strategies of treatment enoxaparin in obese patients (BMI greater than or equal to 30) at Midtown Medical Center.

Methods: The institutional review board approved this retrospective study. A report of all anti-Xa levels ordered and obtained between June 2014 and July 2016 at Midtown Medical Center was generated and reviewed. Patients were randomly assigned a patient identification number. Data was collected and reviewed on a patient data log spreadsheet; this log was only assessable to the primary investigator and primary research associate at the study site. Data collected included enoxaparin dose and frequency, anti-Xa levels, indication for enoxaparin, if anti-Xa levels were correctly collected, bleeding occurrences, creatinine clearance, serum creatinine and patient demographics including age, gender, height and weight. Target anti-Xa levels of 0.6 to 1 units per mL and 1 to 2 units per mL for twice and once daily dosing, respectively, were used to assess for theoretical effectiveness. Patients were excluded if they were under the age of 18, pregnant, not obese (BMI less than 30), if their levels were obtained at a site other than Midtown Medical Center, or received prophylactic enoxaparin dosing (less than 0.5 mg per kg).

Results: A total of 106 patients were reviewed. Ninety-one patients were excluded. Fifteen patients were analyzed: nine male and six female with a mean BMI of 50.8 (range 32-113). Indications included: rule out venous thromboembolism (VTE), history of VTE, treatment of VTE, atrial fibrillation, and bridge therapy for surgery. Twenty-three levels were drawn for

patients receiving twice-daily dosing. Twelve levels (52.17 percent) were within therapeutic range, one (4.35 percent) subtherapeutic and ten (43.47 percent) supratherapeutic . One level was drawn for a patient on once daily enoxaparin; this level was subtherapeutic. The average initial dose was 0.8 mg per kg (range 0.5 to 1.21 mg per kg); average dose associated with therapeutic levels was 0.81 mg per kg. Dose adjustments included one instance of a decrease from 0.89 to 0.71 mg per kg that resulted in a subtherapeutic level (0.34 units per mL), one instance of a decrease from 0.63 to 0.5 mg per kg that resulted in a supratherapeutic anti-Xa level (1.19 units per mL) and two instances of a decrease from 0.97 to 0.47 mg per kg and 0.95 to 0.68 mg per kg that resulted in therapeutic levels (0.66 units per mL and 0.86 units per mL).

Conclusion: Supratherapeutic and therapeutic anti-Xa levels were observed in 43.47 and 52.17 percent of patients respectively, suggesting an initial dose of 1 mg per kg of enoxaparin may be too high of an initial dose in an obese population. Accumulation, indicated by supratherapeutic levels, increases the possibility of adverse events. Patients with a BMI greater than 30 may benefit from routine anti-Xa monitoring if the duration of treatment enoxaparin is expected to exceed several days. Further studies with a larger sample population for a longer study period may be warranted to best determine an ideal initial dose in this population.

Poster Title: Impact of clinical pharmacy interventions in hypertensive population at an academic medical center: a two-year retrospective review

Primary Author: Joy Langley, Mercer University College of Pharmacy, Georgia; **Email:** joy.langley@live.mercer.edu

Additional Author (s):
Maria Thurston

Purpose: Current literature demonstrates that clinical pharmacist involvement in direct patient care of chronic conditions results in better outcomes and decreased heath care costs. The purpose of this study was to assess whether pharmacy interventions and the collaborative model used within an academic outpatient internal medicine clinic are effective when examining blood pressure reduction.

Methods: The institutional review boards of Atlanta Medical Center and Mercer University approved this single-centered, retrospective analysis. The intervention group enrollment occurred between April 2013 and March 2015. Inclusion criteria comprised of age greater than 18 years, a past medical history of hypertension and/or uncontrolled blood pressure as defined by reports of the Joint National Committee on Prevention, Detection, Evaluation, and Treatment of High Blood Pressure (JNC 7, JNC 8), naïve to clinical pharmacy interventions, and who received at least one pharmacist intervention for hypertension during the study period with a baseline blood pressure recorded. Patients enrolled in the control group abided same criteria but lack pharmacy intervention. Patients were excluded if no follow-up visit was recorded or if blood pressure measurements were not documented. The primary outcome measure was absolute change in systolic and diastolic blood pressure between study arms and was analyzed utilizing independent samples t-test. Secondary outcome measures were percentage of patients at hypertension goal per JNC guidelines and quantities and percentages of clinical pharmacy interventions performed.

Results: Mean change in systolic blood pressure measured in mmHg for the intervention (N equals 201) and control groups (N equals 314) were -0.69 and -2.04 respectively with no clinically significant difference (95 percent CI, -5.622 to 2.935, P equals 0.538). Mean change in diastolic blood pressure measured in mmHg for the intervention and control groups were -1.8 and -2.61 respectively with no clinically significant difference (95 percent CI, -3.481 to 1.85, P equals 0.547). Percent at goal in intervention arm was 37.8 percent at study initiation and 43.8 percent at final follow up. Percent at goal in control arm was 21.3 percent at study initiation and 41.4 percent at final follow up. Subsequent analyses of specific interventions lacked statistical and clinical significance.

Conclusion: Although the control arm demonstrated greater blood pressure reduction than the intervention arm, the change was neither statistically or clinically significant. Pharmacy intervention at the site is reserved for more complex patients which may be contributory to lack of blood pressure reduction in said population. A broad range of pharmacy interventions was utilized, many of which are unrelated to hypertension management, and may have diluted intervention arm data resulting in lessened effects of those interventions which contribute to desired outcome.

Poster Title: Treatment of lupus nephritis in an African American patient using cyclophosphamide for induction therapy

Primary Author: Azelia Brown, Mercer University College of Pharmacy, Georgia; **Email:** 10937010@live.mercer.edu

Additional Author (s):
Pamela Moye

Purpose: This case report follows the treatment of a female African American patient who was diagnosed with lupus nephritis. Lupus nephritis is an inflammation of the kidney that is caused by Systemic Lupus Erythematosus (SLE), which is an autoimmune disorder where the body's immune system attacks its own organs and cells. An estimated 40-60% of patients who suffer from SLE are diagnosed with lupus nephritis, with that number increasing to about 75% in African American patients. The presence of lupus nephritis along with SLE can reduce a patient's 10-year survival from 92% to 88%, with an even lower survival rate if the patient is African American. In this case, the patient has a past medical history significant for Juvenile Rheumatoid Arthritis/ SLE, Raynaud's Syndrome and pleuropericarditis that were diagnosed at the age of ten. She presented to the emergency department with significant chest pain that worsened when lying down, shortness of breath, paroxysmal nocturnal dyspnea, four pillow orthopnea and significant swelling in her legs. Physical examination of the patient revealed that she was tachycardic with a pericardial friction rub and had hypertensive urgency. She was believed to have a flare up of her SLE that led to pleuropericarditis and began treatment with intravenous methylprednisone. She also reported a having dark urine and pain upon urination that began three days prior to her hospital admission. Laboratory results revealed that her serum creatinine was elevated. She was treated empirically with antibiotics for a potential urinary tract infection. Rheumatology and nephrology were consulted and a kidney biopsy was performed. She was diagnosed with lupus nephritis and began treatment with cyclophosphamide, an alkylating agent that is a second line treatment option for African American patients with lupus nephritis per the American College of Rheumatology Guidelines for Screening Treatment, and Management of Lupus Nephritis. The Aspreva Lupus Management Study (ALMS) published in November 2009 demonstrated that significantly more African American patients had a response to induction therapy with mycophenolate mofetil

than with cyclophosphamide and less patients in the mycophenolate mofetil group discontinued the study due to adverse effects. The patient received one dose of cyclophosphamide during her hospital stay. Following cyclophosphamide treatment, we began seeing improvement in her lab results and symptoms. Her serum creatinine started to trend back down to normal, BUN levels improved and proteinuria was decreased. Upon the improvement of her symptoms, this patient was discharged with plans to continue cyclophosphamide treatment outpatient.

Poster Title: Management for patient with traumatic cervical fracture associated with asymptomatic vertebral artery occlusion

Primary Author: Pui Shan Chu, Mercer University College of Pharmacy, Georgia; **Email:** puishan.chu@live.mercer.edu

Additional Author (s):
Pamela Moye

Purpose: This case report illustrates the management for a patient who has a traumatic cervical fracture associated with asymptomatic vertebral artery injury. Vertebral artery injury is a relatively rare disease which can be induced by trauma or occur spontaneously. The annual combined incidence for vertebral and carotid artery dissection is 2.6 per 100,000 cases. Vertebral artery occlusion can lead to fatal vertebrobasilar ischemia. This patient was a 17-year-old African America male involved in a motor vehicle crash with rollover. He presented to the emergency room with pulmonary contusions, cervical fracture, subluxation and a small right pneumothorax. His past medical history included asthma, which was controlled by an albuterol inhaler. Upon admission, magnetic resonance imaging of the neck showed fourth cervical vertebra fracture and fourth to fifth cervical vertebra subluxation. The computed tomography angiogram (CTA) showed an occlusion of right vertebral artery due to the traumatic injury. He did not present with any symptoms pertinent to the vertebral artery injury. The patient underwent anterior cervical discectomy and cervical fusion surgery upon admission, and remained on post-operative Jackson-Pratt Drains until 6 days after the surgery. For pharmacological intervention, aspirin 81 mg by mouth once daily was initiated as a primary prophylaxis to reduce the chance of stroke on the eighth day after surgery. Patient was instructed to continue the low-dose aspirin regimen upon discharge for at least 6 months. Patient would follow up two months after discharge with a CTA to assess for the resolution and stability of the injury. Currently, clinicians screen cervical spine injured patients based on regional guidelines and established protocols. Screening is generally provided for the symptomatic patients who have unexplained neurological deficit and asymptomatic patients with significant cervical vertebra or neck tissue injury. This case report suggests that a reliable guideline for extracranial artery injury screening is needed, especially for patients admitted with traumatic cervical injury. The 2011 American College of Cardiology Foundation guideline

recommends antithrombotic treatment using either an anticoagulant or a platelet inhibitor for at least 3 to 6 months for patients with vertebral arterial dissection associated with ischemic stroke or transient ischemic attack. It can also be managed by endovascular revascularization. However, this guideline does not have a specific recommendation for asymptomatic vertebral artery injury. Thus, management for asymptomatic patient is controversial; treatment options include antiplatelet therapy, anticoagulation therapy, or observation alone. A large randomized trial is warranted to determine the optimal treatment strategy for asymptomatic vertebral artery occlusion. The dose and duration of therapy will also need to be addressed in future studies.

Poster Title: Drug-induced Stevens-Johnson syndrome/toxic epidermal necrolysis overlap likely secondary to levetiracetam administration

Primary Author: Amber Cordry, Mercer University College of Pharmacy, Georgia; **Email:** amber.cordry@live.mercer.edu

Additional Author (s):
Alley Killian

Purpose: This case report illustrates an example of drug-induced Stevens-Johnson syndrome/toxic epidermal necrolysis (SJS/TEN) overlap following the initiation of levetiracetam. The patient is a 34-year-old African American female transferred to a large quaternary academic medical center for further work-up after developing multiple organ system failure of unknown etiology. She had a one-month history of fevers, myalgias, and arthralgias. Upon admission, she was found to be febrile with an axillary temperature of 38 degrees Celsius. A bone marrow biopsy revealed mildly hypercellular marrow, with a cellularity of 70% and notable hemophagocytosis. A peripheral blood smear revealed marked neutrophilia, microcytic anemia, and thrombocytopenia. The patient was also found to have severe hypertriglyceridemia, elevated ferritin, and low fibrinogen. Based on this information she was given a diagnosis of hemophagocytic lymphohistiocytosis. On ICU day one, due to worsening altered mental status, an electroencephalogram was performed and revealed focal status epilepticus, which was initially treated with fosphenytoin 2,300 mg IV once, high-dose midazolam continuous infusion weaned over eight days, lacosamide 100 mg IV every 12 hours, and levetiracetam 1,000 mg IV every 12 hours. She began etoposide therapy on ICU day two, of which she received four total doses, given twice weekly. The patient also received a dose of intrathecal methotrexate and IV hydrocortisone on ICU day three due to severe central nervous system involvement. On ICU day six, anticonvulsant dosages were increased to lacosamide 200 mg IV every 12 hours and levetiracetam 1,500 mg IV every 12 hours due to continued seizures. On ICU day ten, the medical team noted a blistering rash had erupted on the patient's feet. By ICU day 17, the blistering rash had extended to approximately 25 percent of her body surface area, with significant skin sloughing of the patient's upper and lower extremities, trunk, back, and oral mucosa. A right thigh biopsy confirmed the suspicion of SJS/TEN. Given that the mucocutaneous reaction had resulted in skin detachment of 10 to 30 percent of the patient's

body surface area, it was classified as SJS/TEN overlap syndrome. Levetiracetam, etoposide, and pantoprazole (initiated on ICU day one for stress ulcer prophylaxis) were potential offending agents in this patient case and all efforts were made to eliminate the cause, including discontinuing levetiracetam, holding the etoposide dose, and changing pantoprazole to famotidine. However, on ICU day 18, the patient decompensated. She went into atrial fibrillation with rapid ventricular rate and became severely hypotensive, refractory to vasopressors. The medical team attributed her shock to a combination of factors, including hypovolemic shock secondary to insensible losses from profound skin sloughing and septic shock secondary to a newly acquired gram negative rod bacteremia. Hours later, she passed away following multiple cardiac arrests.

Levetiracetam, etoposide, and pantoprazole were all suspected culprits in this patient case. However, to date, etoposide and pantoprazole have only been implicated in one mucocutaneous reaction each.[1,2] This is in contrast to the seven case reports associated with skin reactions following the administration of levetiracetam. As confirmed by literature review, there have been two case reports documenting the development of SJS[3,4] and three case reports of TEN[5,6] attributed to the use of levetiracetam. In addition, there have also been two cases detailing other cutaneous lesions associated with levetiracetam use, erythema multiform rash[7] and morbilliform eruptions.[8] Anticonvulsants are a well-known cause of SJS/TEN and evidence of a rash generally appears within seven to 21 days of drug exposure,[9] such as in this patient case. Therefore, it is believed that this case report illustrates the eighth drug-induced skin reaction secondary to the administration of levetiracetam and the first documented incidence of SJS/TEN overlap.

Poster Title: Safety and efficacy of micafungin used for antifungal prophylaxis in neutropenic patients with acute myeloid leukemia at a community hospital

Primary Author: Daniel Sobeck, Mercer University College of Pharmacy, Georgia; **Email:** daniel.sobeck@live.mercer.edu

Additional Author (s):
Angela Shogbon
Bobby Jacob
Carol Story
Adam Bressler

Purpose: Patients with acute myeloid leukemia (AML) develop neutropenia over time due to either treatment or due to the illness itself. These patients are more susceptible to fungal microbes, and can develop invasive fungal infections due to persistent neutropenia. Currently the Infectious Diseases Society of America and National Comprehensive Cancer Network guidelines do not recommend one antifungal agent over another for the prevention of invasive fungal infections in these patients. The purpose of this study was to evaluate the effectiveness and safety of an antifungal medication, micafungin, for prevention of fungal infections in neutropenic patients with AML at a community hospital.

Methods: The Institutional Review Board approved this retrospective study. Patients were enrolled if they were 18 years old or older, diagnosed with AML, neutropenic (Absolute Neutrophil Count {ANC} less than 500) and treated with micafungin 50 mg intravenously once daily at the study institution for antifungal prophylaxis. Exclusion criteria included concurrent usage of an alternative antifungal agent, or an active fungal infection. All patients with a diagnosis of AML seen at the study institution between March 31, 2006 until July, 31 2016 were screened for eligibility. The primary efficacy endpoint was the rates of treatment success versus failure. Treatment success was defined as the absence of a breakthrough fungal infection and lack of need for treatment doses of systemic antifungal therapy. Treatment failure was defined as the occurrence of any breakthrough fungal infection or the need to change to treatment doses of any systemic antifungal therapy. Breakthrough fungal infections was defined as one of the following: cultures showing fungal isolates, evidence of lung infiltrates suggestive of an

invasive fungal infection, persistent fever that was unresponsive to broad spectrum antibiotic treatments for 96 hours or greater, and any condition requiring treatment doses of a systemic antifungal. Safety was assessed by evaluating adverse events based on the Common Terminology Criteria for Adverse Events version 4.0. Data was analyzed using descriptive statistics.

Results: A total of 70 patients with AML were screened for this pilot study, and 15 patients were included. There were 7 females and 8 males. The average age (plus and/or minus standard deviation) was 56 years old plus and/or minus 11.94. The average ANC at time of study inclusion was 155 plus and/or minus 133. A total of 9 patients (60 percent) met the criteria for treatment success with micafungin, 5 patients (33.3 percent) experienced a breakthrough fungal infection during micafungin prophylaxis and did not meet the criteria for treatment success and 1 patient (6.67 percent) was found to have inconclusive results due to early discontinuation of micafungin, and acquired a breakthrough fungal infection later on during their extended hospital stay. A total of 38 treatment emergent adverse events (TEAE) were identified. The most common TEAE were grade 1 elevated alanine aminotransferase (18.4 percent), grade 1 elevated aspartate aminotransferase (13.1 percent), grade 1 hypokalemia (15.7 percent) and grade 3 hypokalemia (13.1 percent).

Conclusion: The usage of micafungin in neutropenic patients diagnosed with AML for antifungal prophylaxis at the study institution was effective at preventing breakthrough fungal infections in over half of these patients. However, usage of micafungin was most associated with slight increases in liver enzyme tests and episodes of hypokalemia. The clinical and statistical significance of this study must be determined in a larger population of patients, including neutropenic patients with other types of acute leukemia such as acute lymphocytic leukemia and acute promyelocytic leukemia, for which antifungal prophylaxis is indicated.

Poster Title: Analysis of immunization training on pharmacists' attitudes on the recommendation and administration of meningococcal vaccinations

Primary Author: Michael Harding, Mercer University College of Pharmacy, Georgia; **Email:** jl475@bellsouth.net

Additional Author (s):
Liza Chapman

Purpose: The relentless discoveries relating to the practice of medicine along with revolutionary advancements in technology pose unique challenges to today's health care professional. These challenges place an increasing importance on the science of training, so the most efficient way to provide the latest evidence based therapy safely to the public can be developed. For this reason, the following study will attempt an analysis of the effects of a meningococcal vaccination training session on a small group of pharmacists. It will analyze the pharmacists' attitude and knowledge before and after the training session concerning recommending and administering meningococcal vaccinations

Methods: The institutional review board of Mercer University approved this prospective pilot questionnaire based study. All pharmacists currently undergoing meningococcal vaccination training as employees of The Kroger Co. Atlanta Division, who provided their informed consent, were administered pre and post training questionnaires. The training was broken into multiple sessions, that were held in geographically convenient locations near the participating pharmacists' home pharmacies. The training sessions are currently ongoing. The questionnaires were divided into three distinct sections. The first section attempted to gather demographic information concerning professional experience levels, age, and gender. The second section attempted to gather information concerning the pharmacists' current attitudes concerning the recommendation and administration of meningococcal vaccinations. The third section of the questionnaire attempted to gather information about the pharmacists' current knowledge concerning the meningococcal vaccinations. The pre training survey served as a control. The pre and post training questionnaires were then analyzed to assess any changes in the attitude or knowledge level of the pharmacists that underwent the training session, any possible

correlation between collected demographic information and their given responses, and to assess the opinions of the pharmacists on the training session.

Results: Preliminary pre and post questionnaire data analysis showed increases in the pharmacists' reported confidence levels concerning their ability to properly recommend and administer the meningococcal vaccinations, and increases in their meningococcal vaccination knowledge scores. A percentage increase of 61.5% was observed in the pharmacists' reported confidence to counsel patients effectively on meningococcal vaccinations, an increase of 46.2% was observed in the pharmacists' reported confidence to identify patients who are indicated to receive meningococcal vaccinations, an increase of 19.7% was observed in reported confidence to administer the meningococcal vaccinations, an increase of 61.5% was observed in reported confidence to recognize common side effects associated with the meningococcal vaccines, and an increase of 53.8% was observed in reported confidence to recognize serious adverse events associated with the meningococcal vaccines. An increase of 13.2% was observed in the pharmacists' meningococcal vaccination knowledge score. Preliminary data analysis also showed slight decreases in some perceived obstacles to recommending and administering the meningococcal vaccinations. A decrease of 23% was observed concerning time limitations being an obstacle in the retail setting and an 8% decrease was observed in the small minority view that pharmacists shouldn't be active in giving vaccinations.

Conclusion: Preliminary data analysis currently indicates that the immunization training did have an impact on the participating pharmacists' knowledge and general attitudes concerning the recommendation and administration of the meningococcal vaccinations. Continued studies with additional refinements to the analysis tool based on these studies, could lead to greater improvements in our current training methods.

Poster Title: Case report of postpartum cardiomyopathy: Rare and complex in nature

Primary Author: Elizabeth Pennington, Philadelphia College of Osteopathic Medicine, Georgia;
Email: elizabethti@pcom.edu

Additional Author (s):
Dusty Lisi

Purpose: About four percent of all pregnancies occurring in western industrialized countries are affected by cardiovascular disease. Of that percentage of the pregnant population, 1 in 2289 to 4000 within the United States will develop into postpartum cardiomyopathy (PPCM). This cardiovascular disease is defined as a non-familial form of idiopathic cardiomyopathy occurring between the last month of pregnancy to five months postpartum. This time limit is extremely important for the purposes of exclusion, which often is the only method of initial diagnosis. Currently there are three diagnostic criteria required for the determination of postpartum cardiomyopathy. These include: timing of incidence, absence of heart failure etiology, and absence of heart disease prior to pregnancy. However, recent evidence suggests that echocardiographic findings of left ventricular dysfunction are also inclusive for diagnosis. Furthermore, PPCM shares many symptoms similar to other cardiovascular etiologies that can present acutely or slowly over time. This makes distinguishing the disease increasingly difficult for health care providers. Many theories about possible disease mechanisms are currently being explored, including low selenium levels, viral infection, stress activated cytokines, autoimmune reactions, hemodynamic stress, and unbalanced oxidative stress. However, these theories have not been accepted by the medical community at this time.
A 35-year-old Hawaiian female was admitted to a general medical and surgical hospital for robotic mitral and tricuspid valve repair due to severe regurgitation. She was 2 months postpartum at admission and had a past medical history for pulmonary edema, thyroid nodule, pre-eclampsia, gestational diabetes, PPCM, and denied substance abuse, including nicotine and alcohol. During surgery, she was discovered to have a patent foramen ovale requiring closure. Post operatively, her condition deteriorated. She developed multiple small infarcts, respiratory failure, acute nephritis, fever with negative cultures, worsening blood glucose control, thrombocytopenia, disseminated intravascular coagulation, and multiple troponin level spikes (highest level was 6.68 nanograms per milliliter).

She was admitted to the cardiovascular intensive care unit and required daily radiology tests, cardiac function tests, intubation, and other critical procedures to stabilize her diminishing state and rising weight status of about 50 pounds from baseline. In addition, she became highly despondent and required evaluation for postpartum depression. The heart failure therapy was specific for symptom management and followed the recommended guidelines. Recent literature suggests the use of bromocriptine can be valuable in this population, but its benefits are limited to the initial stages of presentation of PPCM. Therefore, bromocriptine's use in this patient was not appropriate or needed. Instead, the use of milrinone as a stabilizing agent for vasodilation proved very advantageous. Some caveats for the drug included the concern for potential requirement of long term use and limited rehabilitation facilities capable of managing continuous therapy with milrinone. To offset those concerns, milrinone was tapered after stabilization over 3 to 4 days with success. After 36 days from admission, the management selected proved to be successful and the patient was discharged to a rehab facility with improved functional status from physical therapy and ejection fraction status from 25 to 35 percent. In addition, she was stabilized on guideline-directed medication therapy for heart failure in addition to long-term anticoagulation with warfarin.

As this case suggests, the presentation of a patient with PPCM is complex and contains a higher number of variables then a standard patient with stable or decompensated heart failure. Early recognition and management are of critical importance with a disease state that has a high mortality rate of 28 percent with appropriate therapy. Survivors typically require chronic heart failure management and often require transplantation. More research is still required to further understand the etiology, methods for earlier detection, and further mortality reduction in PPCM.

Poster Title: Evaluating the effectiveness of pharmacy practice residents in preceptorship and academia through postgraduate year 1 (PGY1) teaching certificate program

Primary Author: Melissa Williams, Philadelphia College of Osteopathic Medicine, Georgia; **Email:** melissawil@pcom.edu

Additional Author (s):
Hiral Gandhi
Samuel John

Purpose: The Philadelphia College of Osteopathic Medicine (PCOM) School of Pharmacy developed its first Postgraduate Year 1 (PGY1) pharmacy residency program incorporating a teaching and learning curriculum (TLC). The objective of this study is to evaluate the outcomes of the PCOM PGY1 TLC program.

Methods: The focus of this study is to evaluate the TLC program offered by the PCOM School of Pharmacy PGY1 residency program. This program was launched in 2015 with the purpose of preparing residents to work as clinical pharmacists practicing in various patient care settings, as well as developing skills in preceptorship and academia through a teaching certificate program. The program offers two residency positions.
PCOM pharmacy students evaluated both residents based on didactic skills in the academic setting along with various skills associated with preceptorship through the use of student surveys.
Residents were required to co-precept four fourth year Advanced Pharmacy Practice Experience (APPE) students during their Internal Medicine II block towards the end of the residency year. One survey was sent out to these fourth year APPE students to evaluate the resident's preceptor skills. This survey was IRB approved.
Didactic course evaluations were used to assess the resident's classroom teaching skills. Each resident was required to participate in a 1-2 hour large group lecture, in which they could teach either a didactic or elective course. Out of the 113 pharmacy students taking the surveys, 91 students completed a Dietary Supplements course evaluation for a didactic lecture presented by one resident and 22 students completed a Critical Care course evaluation for an elective lecture presented by the second resident.

Results: Residents were evaluated based on student surveys that rated their teaching techniques and various qualities of preceptorship. The student survey was composed of a questionnaire rating the teaching techniques of their resident preceptors using an effectiveness scale from 0 (Not effective) to 5 (Very effective) for each technique. Residents received an average student rating of greater than 4.25 for each teaching technique. They also received an average rating of greater than 4.75 for various qualities listed in the questionnaire. Course evaluations were used to evaluate residents on their didactic lecture skills in various courses. Residents were evaluated by students who attended the lecture using specific questions from the course evaluation survey that was taken at the end of the term. Students rated the resident on these questions using an agreement scale of 1 (Strongly Disagree) to 5 (Strongly Agree). One resident was evaluated based on their didactic lecture presented in the Dietary Supplements course. This resident received an average rating of greater than 4.3 for each evaluation question. The second resident was evaluated based on their didactic lecture in the Critical Care course elective and received an average rating of greater than 4.6 for each evaluation question.

Conclusion: PCOM School of Pharmacy provides an opportunity for PGY1 residents to participate in various teaching experiences, both at the School of Pharmacy and in the hospital setting. Upon successful completion of this program, each resident will be awarded a teaching certificate at the end of the residency year. The purpose of this study was to evaluate the outcomes of the PCOM PGY1 TLC program. The results of the study suggests that the PCOM School of Pharmacy PGY1 program provides adequate training in teaching experiences that has effectively developed the skills of the residents in academia and preceptorship.

Poster Title: Implementation of residency preparation program to help fourth-year doctor of pharmacy students prepare for postgraduate residency application process

Primary Author: Hiral Gandhi, Philadelphia College of Osteopathic Medicine, Georgia; **Email:** hiralga@pcom.edu

Additional Author (s):
Melissa Williams
Shari Allen

Purpose: The number of applicants applying to postgraduate year 1 (PGY1) pharmacy programs to positions available is approximately 15:1. This increase in pursuit of residency has led to significant competition among applicants, which many do not seem to be prepared for. Many institutions have begun to develop courses that help prepare students for the process. Similarly, Philadelphia College of Osteopathic Medicine-School of Pharmacy (PCOM-SOP) designed a program that focuses on providing individualized time to fourth-year students to help them prepare for the residency application process. This program will also be assessed for its effectiveness in preparing students for this process.

Methods: This Residency Preparation Program was established from the student consensus through an interest survey, which was sent to all fourth-year pharmacy students. In addition to the survey, ideas from different programs that have already implemented similar programs were used to set the foundation of this program. Based on the results of the survey, a proposal was developed and submitted to this institution's executive committee and the Office of Professional and Student Affairs, which approved the program for students interested in pursuing residency. This program takes place over a course of three months with three sessions, each lasting from two to three hours. Each session is capped at 20 students and includes components that the students are interested in. Session one includes an overview of residencies and American Society of Health-System Pharmacists (ASHP) Online Residency Directory and a workshop for building their Curriculum Vitae (CV) and Letter of Intent. Session two includes a discussion with a panel with residents and residency directors and information about ASHP Midyear Clinical Meeting. Lastly, session three focuses on the development of their interview skills by incorporating different types of mock interviews with faculty members. In

order to further prepare students for the residency process, students are expected to participate in required homework assignments for each session.

Results: The interest survey was sent to the Pharmacy Class of 2017, which comprises of 90 students. Out of 90 students, 39 responded with 36 students showing an interest in attending sessions that will provide students with an overview of residency and the application process and a CV and Letter of Intent workshop that provides them with an individualized feedback from the clinical faculty. Moreover, students demonstrated interest in attending sessions that will help them prepare for the ASHP Midyear Clinical Meeting and residency interviews and provide them with an opportunity to attend a panel discussion with residents and residency directors. These components were incorporated into the program to assist students in different aspects of the residency application process. Furthermore, the number of students that signed up for each session are as follows: 23 for session one, 20 for session two, and 20 for session three.

Conclusion: Responses received from the surveys have demonstrated a positive trend towards implementing this program. The effectiveness of this program is determined via surveys that are being sent to students prior to and after each session to assess how much knowledge and skills they have gained after each session. Based on the positive trend, the goal of this program in the future is to expand it and provide opportunity to all pharmacy students enrolled in the pharmacy program to enhance their skills throughout the pharmacy program. Moreover, the goal is to evaluate the effectiveness of this program through residency match rates.

Poster Title: Transdisciplinary team approach that will utilize nursing satisfaction surveys to innovate pharmacy services in an emergency department

Primary Author: Mohammed Abba, Philadelphia College of Osteopathic Medicine - School of Pharmacy, Georgia; **Email:** mohammedab@pcom.edu

Additional Author (s):
John Patka

Purpose: Health-systems across the U.S. use technology such as electronic medical records (EMR), computerized physician order entry (CPOE), automatic dispensing cabinets (ADC), and pharmacy medication carousels to provide timely and efficient pharmacy services. Uncoordinated pharmacy technology can prevent nursing staff from providing optimal patient care due to delays in medication delivery. A transdisciplinary team designed and administered a nursing satisfaction survey to identify gaps in pharmacy services to the emergency department (ED). Utilizing these survey results will aid in innovating pharmacy services to the ED for the future.

Methods: A 17-question survey was administered to nursing staff prior to a pharmacy optimization project. Nursing staff ranked services provided by pharmacy in importance of priority to improve services during the optimization period. These services included timeliness of service, good communication about pharmacy services provided, medication delivery via tube station, and medication stocked in respective ADC machines. Pharmacy Information Technology and EMR Database Administrator provided ADC inventory and medication utilization data. EMR Database Administrators also provided Quick Response (QR) barcode timestamp data for medication orders delivered via pneumatic tube station from the inpatient pharmacy. QR barcode timestamp data will help identify certain "high-alert" medications that need expedited delivery for best patient outcomes (i.e. antimicrobial for a septic patient).

Results: Survey results showed that 72.7% of the respondents take up to 15 trips per day to ADC machines outside of their assigned area. To resolve this, trends in inventory usage were established by comparing ADC inventory reports to CPOE medication orders per ED location respective of department ADC. Trends of usage will be used to optimize ADC medication stock

selected in this project. Sorting trends of usage data by most frequently dispensed, the team will also identify "fast-movers" and ergonomically arrange ADC machines for ease of use and replenishing. Intradepartmental patient-specific medication placement and pneumatic tube system turn-around time were identified as interconnected problems. Sixty eight percent of survey respondents scored a three or below in satisfaction level indicating they are least satisfied with inpatient pneumatic tube station delivery. The team identified multiple delivery locations for patient-specific medications in each department, which created confusion in communication. There will be in-services performed for the respective staff after streamlining the delivery process. About 50% responded to waiting an hour or more for medications after their initial call. Utilizing QR barcode timestamp data, we will prioritize medications by level of urgency and pilot select medications to have expedited delivery protocols.

Conclusion: Using a transdisciplinary team, pharmacy was able to address service problems with a satisfaction survey. Using nursing responses, the pharmacy was able to quantify their areas of improvement as a department and strive to be better. Using an integrated departmental approach, health-systems can restore a healthy balance to their complex systems.

Submission Type: Case Report

Session-Board Number: 3-054

Poster Title: Management of HIV-positive Patients Undergoing Coronary Artery Bypass Graft Surgery: A Case Series

Primary Author: Eva Karam, Philadelphia College of Osteopathic Medicine- Georgia Campus, Georgia; **Email:** evaka@pcom.edu

Additional Author (s):
Dusty Lisi

Purpose: Advances in antiretroviral therapy and management of opportunistic infections with prophylactic antibiotics have greatly improved the prognosis of patients with human immunodeficiency virus (HIV). A large number of patients with HIV develop premature cardiovascular disease as a side effect of their antiretroviral medications and as a complication of their infection. Studies have shown that cardiovascular surgeries, such as coronary artery bypass graft (CABG), may be performed in HIV-positive patients without accelerating immunodeficiency. Furthermore, these patients have acceptable mortality when compared to non-HIV infected patients undergoing similar surgeries. This case series investigates the medication management of patients with HIV following CABG surgery at a 250 bed general medical and surgical hospital.

Patient 1 is a 57 year old male who is HIV positive. At the time of admission, he had an undetectable viral load. He presented to his primary care physician complaining of chest pain. The patient was found to have an abnormal electrocardiogram and he was referred to a cardiologist at our facility. Cardiac catheterization revealed stenosis in multiple arteries and CABG surgery was performed. His home medication regimen upon admission was lisinopril 20 mg daily, pravastatin 20 mg daily, amlodipine 10 mg daily, and Atripla (efavirenz/emtricitabine/tenofovir) 1 tablet daily. At discharge, his antiretroviral medication was switched to Genvoya (elvitegravir/cobicistat/emtricitabine/tenofovir) 1 tablet daily. In addition, the following medications were added at discharge: clopidogrel 75 mg daily, famotidine 20 mg every 12 hours, metoprolol 12.5 mg every 12 hours, furosemide 40 mg daily for 7 days and potassium chloride 20 mEq daily for 7 days.

Patient 2 is a 64 year old female diagnosed with HIV in 1986. At the time of admission, she had an undetectable viral load. She presented complaining of chest pain radiating from throat to back. Cardiac catheterization revealed chronic total occlusion of the left ascending artery with

severe diffuse distal disease and stenosis of multiple cardiac arteries. She was referred to cardiac surgery for CABG. Home medication regimen on admission was metoprolol tartrate 100 mg twice daily, nifedipine extended release 90 mg daily, Klor-Con 20 mEq twice daily, levothyroxine 125 mcg daily, Humalog mix 75/25 subQ twice daily and Atripla 1 tablet daily. New medications prescribed at discharge included amiodarone 400 mg every 12 hours, clopidogrel 75 mg daily, aspirin 81 mg daily, atorvastatin 20 mg every night at bedtime, famotidine 20 mg daily, and cefuroxime 500 mg twice daily. There was no change made to her antiretroviral regimen.

Patient 3 is 59 year old male who presented to with syncopal episodes and an unknown HIV status. He has a past medical history of coronary artery disease and underwent percutaneous coronary intervention (PCI) on two previous occasions. Cardiac catheterization revealed severe multi-vessel disease. CABG was performed on three vessels. His home medications prior to surgery were atorvastatin 20 mg daily, clopidogrel 75 mg daily, aspirin 81 mg daily, abacavir 300 mg daily, efavirenz 600 mg daily, and lamivudine 150 mg daily. New medications added to his regimen at discharge included amiodarone 200 mg every night at bedtime, famotidine 20 mg every 12 hours, metoprolol 25 mg every 12 hours, tamsulosin 0.4 mg daily, insulin NPH 14 units before breakfast and 18 units every night at bedtime, and insulin Regular before meals. There was no change to his antiretroviral regimen.

There is limited data on the optimal cardiovascular and antiretroviral medication regimen for HIV-positive patients post-CABG surgery. Pharmacists can play an important role in assisting the cardiovascular team with deciding on the most appropriate post-operative medication regimen by utilizing guideline-directed medication therapy for both atherosclerotic cardiovascular disease and HIV.

Poster Title: Cost-effectiveness comparison of paliperidone palmitate, paliperidone extended release, aripiprazole once-monthly injectable, and oral aripiprazole in the treatment of schizophrenia

Primary Author: Sean Devine, Philadelphia College of Osteopathic Medicine School of Pharmacy, Georgia; **Email:** seande@pcom.edu

Additional Author (s):
Mark Okamoto

Purpose: The rationale behind long-acting antipsychotics is that they increase adherence thereby decreasing the occurrence of relapse. A reduction in the occurrence of relapse with the use of long-acting injectable antipsychotics should result in a substantial reduction in healthcare costs compared with the use of their oral alternatives. The objective of this research was to construct a decision analysis model to compare the direct medical costs of two once-monthly, long-acting injectable atypical antipsychotics, paliperidone palmitate and aripiprazole once-monthly injectable, and their oral formulations in the treatment of schizophrenia.

Methods: A decision analysis model was created to compare the cost-effectiveness of paliperidone palmitate, paliperidone extended release, aripiprazole once-monthly, and aripiprazole oral. Outcome probabilities for the analysis were obtained from published literature. A search of primary literature was performed. After excluding the majority of trials returned based on relevance and methodology, fourteen trials were used to construct the decision model. The primary outcome for this research was cost per treatment responder. Treatment responder was defined as a patient who experienced a Positive and Negative Syndrome Scale score reduction of ≥ 30%. The secondary outcome was cost per relapse avoided. For each drug, 10,000 patients were simulated through the model for 1 year and total cost and cost effectiveness were calculated. Sensitivity analyses were conducted varying relapse rate for paliperidone palmitate and the responder rate for oral aripiprazole. An incremental cost-effectiveness ratio was calculated for the secondary endpoint to determine the cost per additional relapse avoided when aripiprazole once-monthly is chosen over paliperidone palmitate.

Results: Aripiprazole oral formulation was the dominant strategy for both the primary and secondary outcome with a cost per responder of $22,666.01 and a cost per relapse avoided of $14,473.42. Paliperidone palmitate was found to be marginally dominant over its oral alternative for both the primary and secondary outcomes. Aripiprazole once-monthly injectable was found to be the least cost-effective alternative for the primary outcome. In a sensitivity analysis varying the effectiveness of injectable aripiprazole, it was found that with 5,452 treatment responders (or a responder rate of 54.52%) injectable aripiprazole would reach a level of cost-effectiveness equivalent to extended release paliperidone. In the secondary analysis injectable aripiprazole was found to have a greater number of patients without relapse than paliperidone palmitate but at a higher total cost. The incremental cost-effectiveness ratio of injectable aripiprazole over paliperidone palmitate was $19,917.09 per additional relapse avoided. The studies used to construct the probability of relapse with paliperidone palmitate had a fairly wide variance. A sensitivity analysis varying the range of relapse for paliperidone palmitate showed that if the number of relapses avoided was reduced from 8,429 to 8,403 paliperidone palmitate would be just as expensive per relapse avoided as injectable aripiprazole.

Conclusion: As oral aripiprazole was the dominant strategy in both the primary and secondary outcomes, and oral aripiprazole's dominance was not sensitive to either of the sensitivity analyses, the results of this research do not support the hypothesis that long-acting injectable antipsychotics are cost saving compared to their oral alternatives. However, these results should be interpreted with some caution due to the limitations of the decision model.

Submission Type: Evaluative Study

Session-Board Number: 3-057

Poster Title: Medical use evaluation of vancomycin dosing to create hospital-specific vancomycin nomogram

Primary Author: Tenicia Talley, Philadelphia College of Osteopathic Medicine School of Pharmacy, Georgia; **Email:** teniciajo@pcom.edu

Additional Author (s):
Colleen Cooley
Dusty Lisi

Purpose: Vancomycin is an important agent for the treatment of gram positive infections. Dosing of vancomycin is influenced by multiple factors, including severity of infection, patient weight, age, and renal function. Published literature describes correlations between dosing nomograms and attaining target trough levels. Various methods have been developed estimating pharmacokinetic parameters of vancomycin to calculate the dose. The study compares four different pharmacokinetic models, including Moellering, Birt, revised Matzke, and Creighton to determine which model best fits the patient population. The primary outcome of this evaluation is to assess the appropriateness of vancomycin dosing and create a hospital-specific vancomycin nomogram.

Methods: This is a single-center retrospective study conducted at a 202 bed community general medical and surgical institution. Data for patients receiving vancomycin from November 1, 2014 through May 1, 2016 were included in the study. All data was de-identified in order to preserve patient confidentiality. Patient data were eligible for inclusion if the patient received vancomycin for greater than 48 hours and had a documented steady state vancomycin level. Data on age, loading dose, maintenance dose, vancomycin indication, duration of therapy, vancomycin trough, co-morbidities, concurrent antibiotics causing nephrotoxicity were collected and analyzed. Patients with end-stage renal failure requiring hemodialysis were excluded from the evaluation. Predicted vancomycin levels were obtained using estimated eliminations rates, dosing intervals and maintenance doses. Once a trough level was calculated it was compared to the observed levels for the patient population achieving therapeutic vancomycin trough levels to validate which pharmacokinetic model was the most precise and least biased using root mean square error (RMSE), mean absolute error (MAE), and mean error

(ME). This pharmacokinetic model was used to develop vancomycin dosing nomograms for two different goal trough ranges: 10-15 mg/L and 15-20 mg/L.

Results: A total of 185 patients were enrolled in the study with 45 achieving targeted trough levels, 124 being subtherapeutic and 16 being supratherapeutic at steady state. Patient characteristics included an average age of 60.78 years old, mean body weight of 81.38 kg, and mean creatinine clearance of 87.59 ml/min. There were more male patients than female (103 patients were male and 82 patients were female). The most common indications for vancomycin use included pneumonia, cellulitis, sepsis, UTI and empiric therapy. 176 patients were noted to be receiving concomitant antibiotics therapy. Furthermore, of the 45 patients who achieved therapeutic vancomycin trough levels, the majority of patients (43 out of 35) were receiving concurrent antibiotic therapy. Predicted vancomycin levels were obtained using estimated eliminations rates, dosing intervals and maintenance doses. Once a trough level was calculated it was compared to the observed levels. Based upon the calculated values, it was determined that the Creighton method had the smallest RMSE and MAE (5.23, 3.25) and was the second least biased among the other four methods. By using the Creighton method, two nomograms were developed, one for a targeted vancomycin trough concentration at 10-15 mg/L and the other for a target of 15-20 mg/L.

Conclusion: A vancomycin nomogram is an alternative and efficient way of dosing compared to conventional methods. Furthermore, implementing an institution specific nomogram can lead to a successful clinical response with decreased adverse effects. Since some of the most common indications for vancomycin use require different goal trough ranges, nomograms specific to the goal trough ranges were created to facilitate achievement of optimal vancomycin trough levels.

Submission Type: Evaluative Study

Session-Board Number: 3-058

Poster Title: Retrospective evaluation of ceftaroline use pre and post antimicrobial stewardship intervention in the emergency department

Primary Author: Kaitlyn Champion, South University School of Pharmacy, Georgia; **Email:** kdeshazo@stu.southuniversity.edu

Purpose: Ceftaroline is a fifth generation cephalosporin active against methicillin-resistant Staphylococcus aureus (MRSA) with approval for skin and soft tissue infections and community-acquired pneumonia. High usage in the emergency department (ED) prompted the involvement of the Antimicrobial Stewardship Program (ASP). The purpose of this medication use evaluation was to assess the impact of the ASP intervention on prescribing habits of ceftaroline in the ED. Frequent use of ceftaroline coupled with its high cost does not benefit the hospital or the patients prescribed it. It is vital that ceftaroline is used only when required to decrease the potential for resistance.

Methods: The institutional review board approved this randomized, retrospective evaluation of ceftaroline usage in a rural hospital that sees an average of 2,900 patients a month in the ED. In May 2015, the Pharmacy and Therapeutics Committee voted for the removal of ceftaroline from the floor stock in the emergency department and for a memo to be composed by the ASP to provide education on appropriate use. In July 2015, ceftaroline was removed from the Omnicells and the lead ASP pharmacist attended the Department of Emergency Medicine meeting to review the memo and ceftaroline's removal from the floor stock. A pre-intervention report was created for patients who received ceftaroline in February and March of 2015. A post-intervention report was created for patients who received ceftaroline between the months of August 2015 and July 2016. In each report, thirty patients were selected using simple random sampling, every fourth patient profile was chosen for review. The primary outcome measures were total doses per 1000 patient ED visits and indication for use. Additional data collection included: dose of ceftaroline, glomerular filtration rate, allergy to vancomycin, infectious disease consult, and history of MRSA. This information was collected, de-identified, and analyzed using descriptive statistics.

Results: An analysis of ceftaroline usage was performed comparing January and February data from the years of 2015 and 2016. The data in 2015 showed 3.74 doses per 1,000 patient days while data in 2016 revealed 0.76 doses per 1,000 patient days. Of the indications for prescribing ceftaroline, 83 percent in the pre-intervention arm were FDA approved as opposed to the post-intervention arm where 93 percent of indications were FDA approved. The dosing of ceftaroline showed no change in pre and post intervention as both sets of patients had four incorrect doses. There was an increase in a history of MRSA infections, 6 percent versus 23 percent, and an increase in allergies to vancomycin, 10 percent versus 13 percent. Admission rates for patients presenting to the emergency department that were prescribed ceftaroline increased from 37 percent to 70 percent.

Conclusion: The removal of ceftaroline from the emergency department showed an improvement in physicians prescribing habits for the FDA approved indications. There was a five-fold decrease in doses per 1,000 patient day following the ASP intervention. However, there was no change in accuracy of dosing ceftaroline correctly. Clinical pharmacist interventions are essential in improving hospital drug use and should be utilized regularly.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Descriptive Report

Session-Board Number: 3-059

Poster Title: Concentrated insulin's impact on hypoglycemia adverse drug reactions

Primary Author: Jessica Bankston, South University School of Pharmacy, Georgia; **Email:** jlbankston22@gmail.com

Additional Author (s):
Caroline Bramlett
Kimberly Barefield
Andrea McKeever

Purpose: Insulin is a mainstay of treatment for individuals with diabetes. Hypoglycemia is a major adverse drug reaction (ADR) associated with insulin. As insulin resistance increases, larger doses of insulin are required to maintain euglycemia. With larger volumes of insulin injected subcutaneously, absorption can become unpredictable. Concentrated products address high injection volume burden. Until recently, Humulin R U-500 was the only concentrated insulin on the market. Since 2015, degludec U-200 and glargine U-300 have been approved. The goal of this study was to determine if the increase of concentrated insulins on the market has correlated with an increase of hypoglycemia ADRs.

Methods: Data on the concentrated insulins was obtained from the Food and Drug Administration (FDA) Adverse Event Reporting System (FAERS) Latest Quarterly Data Files at FDA.gov. The FAERS data files that were of interest included year 2012 (Quarter 4), year 2013 (Quarters 1-4,) year 2014 (Quarters 1-4), and year 2015 (Quarters 1-4). After downloading and converting the files, each file was searched to see if it contained information pertaining to the three drugs (Humulin R U-500, degludec U-200, and glargine U-300).

Results: In reviewing the files, some of the quarters did not contain information on any of the three insulins. The years with no data included year 2012 (Quarter 4) and year 2013 (Quarters 1-4). This was partly due to the time of approval of the newer concentrated insulins. For example, glargine U-300 was not introduced to the market until February 2015, and degludec U-200 was not introduced to the market until 2015. There were no reported ADRs on Humulin R U-500 in the earlier portion of the data, since its market approval was in 1994. When

analyzing the remaining data, there was a clear trend of increased ADRs of hypoglycemia with the addition of new concentrated insulins entering the market.

Conclusion: With increasing insulin resistance in individuals, concentrated insulins can decrease the burden of injecting large volumes of insulin therapy. With the introduction of new concentrated insulins to the market, there was an observed increase in hypoglycemia ADRs. This finding brings attention to the need for greater patient and provider education regarding concentrated insulin. Understanding the properties of this new formulation of insulins is critical for safe dosing and administration.

Poster Title: Evaluation of naloxone accessibility state legislature and trends of drug overdose-related deaths

Primary Author: Ryan Hoffman, South University School of Pharmacy, Georgia; **Email:** hoffman8295@stu.southuniversity.edu

Additional Author (s):
Lianet García
Sarah Hinton
Andrea McKeever
Lilia Macías-Moriarity

Purpose: Drug abuse is a national epidemic impacting America. Additionally, drug-related overdoses especially those resulting in death have reach proportions that state legislatures are attempting to curb the trend. Most notably, states are addressing opioid-related overdoses by increasing naloxone accessibility to populations at risk of an acute opioid overdose. The prescription drug naloxone is an effective reversal agent for acute opioid overdose. However, it is unknown whether legislative action to prevent drug overdose-related deaths is effective. Therefore, the purpose of this project is to determine if deaths associated with drug overdoses have changed following state naloxone accessibility legislation being enacted.

Methods: Data from the Morbidity and Mortality Weekly Report (MMWR) National Vital Statistics System on deaths related to drug overdoses was gathered for 2013 and 2014. A review of state naloxone accessibility legislature was performed and dichotomized between states that had a change in legislation versus those states that did not have changes in legislation between 2013 and 2014. A Wilcoxon signed rank test was used to compare deaths among states with changes in legislation and a Mann-Whitney U test was used to compare deaths between states who enacted changes in legislation versus those states with no change. Alpha error was set apriori at 0.05. This investigation utilized secondary public data sources and was exempt of IRB approval.

Results: Deaths for drug overdose from 50 states plus the District of Columbia for 2013 and 2014 were analyzed (n=51). Eight states (Kentucky, Maryland, New Jersey, North Carolina, Oklahoma, Oregon, Vermont, and Virginia) executed a change in legislative action during 2013; in these 8 states, there was no significant difference in deaths between 2013 and 2014, p=0.093. No statistically significant difference in deaths was found between states with changes in legislation versus those without changes in legislation in 2013 (p=0.516) and 2014 (p=0.437).

Conclusion: Although the enactment of naloxone accessibility legislature has led to increased availability of naloxone to the public, the total number of fatal drug overdose has continued to rise. No significant difference in deaths was found among states that had a change in naloxone legislation nor between states with a change in legislation versus without a change in legislation. Further assessment of the impact of naloxone accessibility legislature should be investigated as updated data on opioid-related overdose mortality becomes available.

Poster Title: Trends of Marijuana Use and Related Indicators in States with Approved and Pending Recreational Marijuana Use

Primary Author: Jolie Russell, South University School of Pharmacy, Georgia; **Email:** jolie.dunn@yahoo.com

Purpose: Since 2012, four states and the District of Columbia approved laws permitting the legal sale of recreational marijuana to adults 21 years and older. Five states vote to legalize recreational marijuana this November. With public opinion dramatically rising in favor of marijuana, the purpose of this research was to compare and contrast trends of marijuana use and related indicators in states with approved and pending recreational marijuana use.

Methods: We conducted a literature review of state legislation to identify states with approved and pending recreational marijuana laws. Following identification of the population of approved and pending states, we evaluated annual National Survey on Drug Use and Health (NSDUH) data during the period 2002 to 2014 to identify trends of marijuana use and related indicators among all persons aged 12 years or older. These indicators included percentage of past year marijuana use; percentage of marijuana initiation in the past year; percentage of perceived great and no risk associated with smoking marijuana once or twice a week; percentage of past year marijuana dependence and abuse; and percentage of respondents perceiving that no penalty would result for the first offense possession of an ounce or less of marijuana. Using descriptive data techniques, we depicted the data providing side-by-side comparisons of states with approved and pending recreational marijuana legislation.

Results: The percentage of past year marijuana use among all persons aged 12 years or greater increased from 2002 to 2013. Use ranged from 10.3 to 16.1 and 13.6 to 16.2 percent in 2002, increasing to 12.9 to 20.3 and 19.4 to 21.4 percent in 2013 in states with pending and approved recreational marijuana use, respectively. In contrast, use ranged from 7 to 13 and 8 to 16.9 percent, increasing to 8.4 to 13 and 11.3 to 20.6 percent in states without either medicinal or recreational cannabis use and states with approved medicinal cannabis use only, respectively. The change in percentage of marijuana initiation in the past year was relatively flat in states pending recreational legislation approval, but increased approximately 40 percent in states with approved laws. Compared to states with pending legislation, the perception of great risk

associated with once or twice weekly marijuana use decreased more consistently and strongly in states with approved recreational laws, and approached an equal percentage of respondents who felt that there was no risk. We observed inconsistent data trends between groups regarding marijuana dependence and abuse. Lastly, more individuals perceived no penalty for marijuana possession in states with approved recreational laws.

Conclusion: Trends in marijuana use are increasing regardless of state legislation. Prevalence of use, percentage of new use initiation, percentage of individuals perceiving no risk from using marijuana once or twice a week, and the perception that no penalty would occur if possessing one ounce of marijuana was greater in states with approved recreational marijuana laws. Less the limited marked increase in the perception of no penalty from two states, sufficient data following approval of recreational marijuana use does not exist. Consequently, forecasting the impact of marijuana deregulation in states pending legislation cannot be determined.

Poster Title: Lack of reported data concerning the use of dietary supplements and their adverse effects resulting in emergency department visits

Primary Author: Carina McCrea, South University School of Pharmacy, Georgia; **Email:** carinamccrea@gmail.com

Additional Author (s):
Jade Haas
Amennah Little

Purpose: After implementation of the Dietary Supplement Health and Education Act of 1994, there has been a relevant amount of hospitalizations, disabilities and deaths regarding dietary supplement use due to exemption of regulation and standardization by the Food and Drug Administration. Dietary supplement suppliers are only required to submit a MedWatch form to the Food and Drug Administration concerning reported cases, deemed "serious adverse events", potentially leaving consumers vulnerable to ineffective and/or toxic therapies. This study reviews the use of supplements and the deficiency of national data concerning adverse effects, which resulted in admissions to the emergency department.

Methods: Retrospective analysis of articles concerning adverse events caused by dietary supplements amongst adults resulting in visits to the emergency department. Supplement usage data collected from National Health Statistics Reports combining information from 88,962 adults aged 18 and over in 2002, 2007, and 2012. 30-day and 12-month survey recalls were evaluated concerning dietary supplement use. Emergency department visits associated with adverse events precipitated by dietary supplement use was collected from national representative surveillance data. 9 years of data, gathered from January 2004 to December 2013 in 63 hospitals participated in the National Electronic Injury Surveillance System–Cooperative Adverse Drug Event Surveillance project conducted by the Centers for Disease Control, Food and Drug Administration, and Consumer Product Safety Commission, were used to make evaluations. The previously gathered data was compared and assessed. Statistical review in the original assessments included two-sided t-tests and the Statistical Analysis System software (SURVEYMEANS, SURVEYFREQ, SURVEYLOGISTIC, SURVEYREG).

Results: Dietary supplements were the most commonly used complementary health approach amongst adults in all three reporting years (18.1%). Of the dietary supplements analyzed; fish oil, glucosamine, chondroitin, echinacea, flaxseed, and ginseng were the most frequent and consistently used supplements in the study population. Though the prior mentioned supplements were the most used, weight loss supplements were the biggest offenders totaling 25.5% of emergency department visits (95% CI: 23.1-27.9). Emergency department visits stemming from adverse events associated with dietary supplement use was calculated on average to be 23,005 annually (95% CI: 18,611-27,398). These visits culminated to an annual average of 2,154 hospitalizations (95% CI: 1342-2967). A total of 5,943,429 adverse effects were reported to the Food and Drug Administration in a 9 year period, of which only 0.22% (13,144) were caused by dietary supplements.

Conclusion: The health and safety benefits of dietary supplements are still unclear, despite the significant influence they hold as a widely used complementary health approach. Consistent feedback and education on dietary supplements and their adverse effects are necessary to decrease the amount of visits to the emergency department. Although dietary supplement-related adverse events which resulted in emergency department visits comprise a small percentage compared to visits reported for pharmaceuticals; regulating dietary supplements under presumed safety should be a major concern to the Food and Drug Administration.

Poster Title: Evaluation of human 4 factor prothrombin complex concentrate (4FPCC) for anticoagulation reversal at a Level 1 trauma and comprehensive stroke center

Primary Author: Vincent Tran, The University of Georgia College of Pharmacy, Georgia; **Email:** vince312@uga.edu

Additional Author (s):
Paul Bauman
Andrea Newsome
Christina DeRemer

Purpose: Vitamin K antagonist reversal agent, 4FPCC, is approved for the rapid reversal of warfarin. When administered with vitamin K, 4FPCC reduces the international normalized ratio (INR) values to less than 1.3 within thirty minutes in the majority of patients. The severity of anticoagulation induced bleeding situations may warrant the use of 4FPCC for the reversal of alternative mechanistic anticoagulants that lack reversal agents since the rapid development of other oral agents that have exceeded the development of focused reversal agents. The primary objective of this study is to evaluate the use of 4FPCC at an academic medical center.

Methods: A retrospective chart review was conducted from April 2013 to August 2016. All patients who had a 4FPCC order placed at any point during the emergency room stay or hospitalization were included. Data collection comprised of pertinent patient demographics, anticoagulation agent and indication, type of bleed or urgent implication for 4FPCC, and doses prescribed with confirmation of administration of 4FPCC. Pertinent laboratory values gathered were: INR, PT, APTT, TT, viscoelastic assays, and ecarin. Other data points collected included: use of vitamin K, use of fresh frozen plasma, adverse effect profile related to 4FPCC administration, and patient disposition. Descriptive statistics were performed. This project was approved by the Augusta University institutional review board as a not human subjects research. This project is also a part of the health system medication use evaluation and improvement program.

Results: Inclusion criteria were met in 16 orders. Of the 13 patients with available target INR ranges, five (38.5 percent) had an admission INR within the indicated target range, four (30.7 percent) had supratherapeutic INR values, and four (30.7 percent) had a subtherapeutic INR. Of the 11 patients who had documented 4FPCC administration, eight patients (72.7 percent) received 4FPCC for its approved indication for the reversal of warfarin. Incorporating INR values for dose guidance, only one out of eight patients received the incorrect 4FPCC dose based on the packet insert. At discharge, three out of the eight patients (37.5 percent) expired and five patients (62.5 percent) continued care at rehabilitation, one being the overdosed patient. The remaining three out of 11 patients (27.3 percent) received 4FPCC for the off-label reversal of either non-warfarin anticoagulants or no anticoagulation use. Dosing was varied in the off-label group, ranging from 25 to 50 units per kilogram per dose of 4FPCC. At discharge, two out of three patients received continued care at an outside location, and one patient expired.

Conclusion: Overall, the use of 4FPCC for its approved indication appears to be dosed appropriately. Further, there was a greater than 60 percent survival following approved use. Due to the lack of established dosing strategies of 4FPCC for off-label uses and the lack of an institutional protocol, off-label dosing varies widely. Although our institution's usage of 4FPCC is small, survival numbers are consistent between on-label and off-label indications. Future research and the implementation of a standardized dosing protocol should be conducted on a larger population to further validate both on-label and off-label dosing in the absence of alternative reversal options.

Poster Title: Evaluation of an autologous hematopoietic stem cell transplant (auto-HSCT) mobilization protocol at an academic medical center

Primary Author: Gail Smith, The University of Georgia College of Pharmacy, Georgia; **Email:** gailss@uga.edu

Additional Author (s):
Joshua Wyche
Amber Clemmons

Purpose: Collection of CD34-positive stem cells for auto-HSCT can occur via apheresis after granulocyte colony stimulating factor (GCSF, filgrastim) administration for 4 or 5 days. Mobilization failures or an increased number of apheresis sessions, which are costly and not devoid of risk, may occur with GCSF alone. Plerixafor, a chemokine receptor-4 antagonist, added to GCSF has been shown to increase stem cell yield and reduce days of apheresis; Cost-effective utilization of plerixafor is paramount. The purpose of this study was to evaluate a pharmacy and therapeutics committee-approved mobilization protocol using pre- and post-implementation data at an academic medical center.

Methods: This retrospective, IRB approved medication use evaluation included all auto-HSCT patients who underwent apheresis since protocol approval (n=23, post-implementation cohort) as well as the same number of patients prior to protocol implementation (n=23, pre-cohort). Both filgrastim and plerixafor were available per physician discretion prior to protocol approval. The protocol and its associated order forms were enacted to standardize dosing while maximizing mobilization efficiency with a goal to reduce number of apheresis sessions while utilizing plerixafor only in those patients deemed high risk of failure or who needed collection of cells for tandem transplantation (e.g., myeloma). The protocol divided patients into single transplants (goal 5 million cells/kg) and anticipated tandem transplants (goal 10 million cells/kg). Patients on the single algorithm only received plerixafor if day 5 CD34 was less than 20, while tandem patients received day 5 plerixafor routinely. Only patients with peripheral CD34-positive counts less than 60 not at goal collection after one apheresis received additional plerixafor. The protocol established dose rounding for filgrastim and weight/renal function appropriate dosing for plerixafor. Outcomes compared between the pre- and post- protocol

cohorts included: appropriateness of GCSF/plerixafor utilization and dosing, number of apheresis sessions, stem cell yield per day and total (million cells/kg), whether a patient received their transplant, and stem cell amount infused. Demographic data collected included age, gender, type of malignancy, weight, and renal function.

Results: Twenty-five pre-protocol and 23 post-protocol charts were screened resulting in 23 patients proceeding to apheresis in each cohort. Forty-six patients (33 percent lymphoma, 66 percent myeloma/amyloidosis) were evaluated: median age 61 years, 59 percent male. Pre-protocol data: median 4.2 million cells/kg collected in 1(n=8), 2(n=11), 3(n=2), 4(n=1), and 6(n=1) apheresis sessions; 96 percent received transplantation. First day of apheresis: median CD34 count was 53.5 cells/microliter (range 7-186). Post-protocol cohort doses were appropriate per weight/renal function in 100 percent of filgrastim and 81 percent of plerixafor. Further, 71 percent of plerixafor doses were appropriate per protocol (n=4 patients receiving n=8 inappropriate doses.) Post-protocol data: median 4 million cells/kg collected in 1(n=10), 2(n=10), 3(n=3) apheresis sessions; 91 percent revieved transplantation with one additional transplant pending. Median and range of peripheral CD34 counts for post-protocol patients on single (n=10) and tandem (n=13) algorithms were 51 cells/microliter (8-825) and 124 cells/microliter (28-348), respectively. However, half of patients on single algorithm received plerixafor off protocol. All forty-six patients who completed apheresis achieved the minimum of 2 million cells/kg, 78 percent in both pre- and post-protocol cohorts achieved at least 5 million cells/kg, and 43 vs. 54 percent achieved greater than goal 10 million cells/kg, respectively.

Conclusion: Implementation of a protocol to standardize auto-HSCT mobilization did not change either the number of cells collected per session (median approximately 4 million cells/kg) or apheresis sessions required (median n=2). The protocol did reduce the number of patients with greater than 2 apheresis sessions (17.4 vs. 13 percent) which represents 16 versus 9 apheresis sessions for those 4 versus 3 patients. However, non-adherence to the protocol (approximately 30 percent of plerixafor was administered off protocol) confounds the clinical interpretation of the protocol's effectiveness. Going forward, education of prescribers and pharmacists will be beneficial to increase adherence to the protocol.

Poster Title: Predictors of hospital mortality for multi-drug resistant Acinetobacter baumannii infections in critically ill adults

Primary Author: Amy Taylor, The University of Georgia College of Pharmacy, Georgia; **Email:** aparkstaylor@gmail.com

Additional Author (s):
Smit Patel
Anthony Hawkins
Carlos Franco-Paredes
Daniel Chastain

Purpose: Acinetobacter baumannii, a gram-negative pathogen with intrinsic resistance, can cause infection by both environmental exposure and nosocomial transmission. Due to increases in multidrug resistant (MDR) infections, this bacterium poses an imminent threat associated with increased length of stay and mortality. Despite understanding its mechanisms of resistance, factors associated with poor outcomes of MDR A. baumannii infections are not fully understood. Previous studies have examined risk factors for hospital-acquired A. baumannii infections, but few have included non-hospital acquired infections. This purpose of this study is to identify factors that predict morality in critically ill patients with MDR A. baumannii infections.

Methods: This institutional review board approved, single-center retrospective cohort study examined patients 18 years of age with culture confirmed MDR A. baumannii infections who were admitted to the medical, surgical, or cardiac intensive care unit (ICU) between January 1, 2012 and July 31, 2016. For this study MDR was defined as resistance to more than one class of antimicrobials. Patients were excluded if they were pregnant, had an anaphylactic allergy to penicillin, or a positive urine culture with A. baumannii. Data collected included demographic characteristics, antibiotic use within 3 months of admission, incidence and duration of mechanical ventilation, prior hospitalizations, surgeries, or previous long-term care facility (LTCF) stay within 12 months. Clinical parameters involving laboratory, and microbiologic data were identified at time of admission, and time of positive culture collection. After dividing the population into survivors and nonsurvivors, data was analyzed by descriptive statistics. The

primary outcome was to determine predictors of mortality. Secondary outcomes focused on treatment results including microbial cure, time to appropriate therapy, and ICU length of stay.

Results: Eighteen patients were included in this study; 61 percent males, with a mean age of 56.8 plus or minus 20.1 years. A higher mortality rate was observed in patients greater than 50 years of age, 58 percent versus 17 percent respectively. Seventy-eight percent were admitted from LTCF; twelve resided in a single facility. ICU length of stay was not related to mortality. Sixty-seven percent of patients were on chronic ventilation, and 22 percent initiated after admission, with respective mortality rates of 21 and 75 percent. Sixty-six percent had respiratory comorbidities; those with Asthma were noted to have a higher mortality rate (2/2) compared to those with Chronic Obstructive Pulmonary Disease (0/2). Sequential Organ Failure Assessment (SOFA) scores on admission greater than 10 were associated with increased mortality (78 percent, 7/9). Patients with bloodstream infections had a higher mortality rate compared to respiratory tract infections, 63 percent (5/8) and 30 percent (3/9), respectively. Polymicrobial infections further increased mortality rates. Of the 22 percent of patients who were started on empiric therapy not active against organisms isolated, 75 percent died. An increase in serum creatinine greater than 1.5mg/dL during hospitalization was associated with 100 percent (4/4) mortality.

Conclusion: This study analyzed patient history, comorbidities, culture data, and clinical labs to provide predictors of mortality in patients infected with MDR A. baumannii. Advanced age, increasing serum creatinine, and SOFA scores greater than 10 were associated with a greater mortality. Respiratory comorbidities and mechanical ventilation status were also factors. Increased rates of mortality were seen in bloodstream involvement, polymicrobial infections, and empiric antibiotic selection without in vitro activity. By determining predictors of mortality, patients who would benefit from increased care can be identified and provided closer monitoring with more aggressive antimicrobial therapy.

Submission Type: Evaluative Study

Session-Board Number: 3-066

Poster Title: Retrospective evaluation comparing a non-benzodiazepine versus benzodiazepine based sedation strategy during targeted temperature management following non-traumatic cardiac arrest in critically ill adults

Primary Author: Natalie Chong, The University of Georgia College of Pharmacy, Georgia; **Email:** nychong@uga.edu

Additional Author (s):
Jake Davis
Anthony Hawkins

Purpose: Targeted temperature management (TTM) following non-traumatic cardiac arrest is a therapeutic approach intended to improve neurologic outcomes. Complications associated with TTM include shivering and hypotension. Current guidelines suggest a non-benzodiazepine strategy over benzodiazepines, although this is derived from data targeting light sedation. The need for and choice of sedative agents are not known in patients requiring TTM. Side effects associated with various sedatives may affect complication of TTM. The purpose of this study is to compare non-benzodiazepine and benzodiazepine sedation strategies in critically ill adults during TTM.

Methods: This was a single-center retrospective observational cohort study conducted at a large community teaching hospital. It was approved by the institutional review board with waived consent. All patients over 18 years old admitted to the medical, surgical, or cardiac intensive care units (ICU) who underwent TTM between October 1, 2015 and July 31, 2016 were eligible for inclusion. Patients were excluded if TTM was initiated for any indication other than non-traumatic cardiac arrest or if they did not receive any sedative agents. Patients were divided into two groups for comparison based on the choice of sedative received for deep sedation: non-benzodiazepines (i.e. propofol) and benzodiazepines (i.e. midazolam or lorazepam). Demographic characteristics, type and amount of analgesic and sedative medications, incidence of adverse effects, and mortality were extracted from the electronic medical record. The primary outcome of the study was the need for neuromuscular blocking agents (NMBA). Secondary outcomes included the need for vasopressor support and in-hospital mortality. Descriptive statistics were used to analyze the data.

Results: A total of 19 patients were evaluated for inclusion. Five patients were excluded for TTM indication other than non-traumatic cardiac arrest (n equals two) and no use of sedative agent (n equals three), leaving 14 patients to be included for analysis. Twelve patients received a non-benzodiazepine based strategy, and two patients received a benzodiazepine sedation strategy. No patients received lorazepam in the benzodiazepine group. Demographic characteristics including age and admission weight were similar at baseline between the two groups. Severity of illness determined by a Sequential Organ Failure Assessment (SOFA) score appeared to be similar, with a SOFA score of 11.8 in the non-benzodiazepine group and 10.5 in the benzodiazepine group. The need for NMBA occurred in six (50 percent) patients in the non-benzodiazepine group compared with two (100 percent) patients in the benzodiazepine group. Vasopressors were required in ten (83.3 percent) patients in the non-benzodiazepine group compared with two (100 percent) patients in the benzodiazepine group. Eight (66.7 percent) patients and one (50 percent) patient died in the hospital in the non-benzodiazepine and benzodiazepine groups, respectively.

Conclusion: The interim analysis showed the need for NMBA to be more profound in the benzodiazepine group. This finding may suggest that side effects from a benzodiazepine approach may impact complications of TTM such as shivering more so than a non-benzodiazepine approach. However, the preferred sedative agent for deep sedation in TTM remains uncertain. Further investigations are warranted to assess the safety and efficacy of these sedation strategies.

Poster Title: Pharmacists as educators: A survey of nurse responders during an epinephrine formulation shortage

Primary Author: Andrew Russell, University of Georgia, Georgia; **Email:** aruss24@uga.edu

Purpose: Approximately 209,000 hospitalized patients in the U.S. face cardiac arrest every year. These emergencies are seldom expected, making familiarity with crash cart supplies one of the most crucial factors for rescue. Floor nurses are often the first to arrive and need to be comfortable administering urgent epinephrine, but drug shortages can negate consistency between epinephrine administration methods. This survey of nurses in an Atlanta, GA hospital during a widespread crash-cart epinephrine change aims to prepare responders by finding an optimal model of preemptive pharmacy education.

Methods: Due to a shortage of standard crash-cart epinephrine 1mg/10mL syringes, an Atlanta hospital planned to substitute them for 1mg/1mL vials with new administration instructions. In order to best prepare nursing staff for this change, five simple methods of pharmacy-led education were devised and laid out on a survey sheet for nurse response. Methods posited were: (1) pharmacist outreach to charge nurses; (2) educational flyers in break areas; (3) short, in person pharmacy demonstrations; (4) A hospital-specific intranet message; or (5) 'other,' in which nurses could specify an alternative method. Questions were posed in a face-to-face manner in randomized order. Method options were not mutually exclusive, enabling the nurses to select as many of the options as they preferred. However, each nurse sampled was also encouraged to limit selections to his or her top 2 options. Nurses could specify any option for 'other' that they could think of, with no limitations. Inclusion criteria were any patient-caring nurse who was employed by the hospital health system. Exclusions were non-patient care nurses and any non-nurse personnel. Nurses who were asked and chose not to reply were also included. No health-related information or personal data of any sort were collected while surveying, and an IRB exemption is currently pending.

Results: Amongst 13 units, 50 nurses were sampled and included in the final results. Of those 50, 7 were from critical care units. Overall, 30 (60%) nurses selected "short, in person pharmacy demonstrations;" 21 (42%) selected "educational flyers in break areas;" 16 (32%) selected "pharmacist outreach to charge nurses;" and 8 (16%) selected "hospital-specific intranet message." 'Other' educational methods concocted by nurses included: making it a shift huddle highlight (2 nurses); involving the designated unit educator (3 nurses); using simple and clear labeling on crash cart drug tray; ensuring that both day and night staff were notified of changes; and holding a pharmacy specific seminar. Two nurses highly encouraged employing all of the options in order to provide wide reaching support. One surveyed nurse chose not to provide feedback.

Conclusion: The majority of nurses preferred an in-person demonstration, with informational flyers being the second most valued method. By employing both of these tactics, pharmacists can help keep other healthcare professionals updated and prepared during an emergent drug shortage. While not surprising, these results are also indicative of the receptiveness of nurses to pharmacist involvement and communication. Many hospital systems may currently underutilize pharmacists in this particular educator capacity due to a lack of time or resources, but additional involvement would likely improve outcomes in cardiac arrest and other disease states.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Evaluative Study

Session-Board Number: 3-068

Poster Title: Evaluation of the use of isavuconazonium at an academic medical center

Primary Author: Emily Murray, University of Georgia, Georgia; **Email:** violinemily@gmail.com

Additional Author (s):
Paige Wallace
Sonal Patel
J Russell May

Purpose: Isavuconazonium is a broad-spectrum antifungal approved by the FDA in 2015 to treat invasive aspergillosis and invasive mucormycosis. Due to it possessing several favorable properties (no renal dose adjustment, high oral bioavailability, oral and intravenous formulations, etc.), it may readily be over and improperly utilized if not monitored by pharmacists. The purpose of this medication use evaluation was to ascertain the characteristics of patients treated with this medication at our medical center and to evaluate the outcomes of these patients.

Methods: The institutional review board approved this quality improvement project. All patients receiving isavuconazonium at our medical center from April 2015 to August 2016 were included in this retrospective chart review. Results were entered into and analyzed using Excel. Patient factors analyzed were age, gender, indication for isavuconazonium, intravenous or oral form utilized, whether or not infectious disease providers were consulted and whether or not they approved the use of isavuconazonium, previous antifungal use in the past 90 days, duration of isavuconazonium therapy, isolation of fungal organisms, and comorbidities (using the Charlson comorbidity index). Outcomes analyzed were adverse effects secondary to isavuconazonium use, breakthrough fungal infections while on isavuconazonium and discharge disposition.

Results: During this 16-month period, 18 patients were treated with isavuconazonium at our facility. The average age of a patient in our study was 47 years old with a median of 54.5 years. The most common indication isavuconazonium was utilized for was fungal pneumonia. Fifty percent of patients utilized strictly the intravenous form, 22 percent utilized strictly the oral form and 28 percent utilized both formulations. Infectious disease providers were consulted

and approved the use of isavuconazonium 100 percent of the time. Antifungal therapy in the past 90 days had been provided to 83 percent of the patients with the most common antifungal being voriconazole followed by posaconazole. The average duration of use of isavuconazonium (excluding patients on indefinite use) was 24 days. Fungal organisms were isolated in 44 percent of patients with the most common organism being aspergillus. The average Charlson comorbidity index score was 2.5. Only one patient had a potential adverse effect due to isavuconazonium noted with it being eosinophilia. No patients had a documented breakthrough fungal infection while on isavuconazonium. Eleven patients were alive at discharge while 7 passed away before discharge.

Conclusion: The use of isavuconazonium at our institution seemed to mostly be devoid of adverse effects. Additionally, the data indicates that it helped in preventing any breakthrough fungal infections while the patient was being treated. While ideally, we would like 100 percent of our patients to be alive upon discharge, many of these patients presented in an already immunocompromised state due to leukemia or lymphoma treatment.

Submission Type: Evaluative Study

Session-Board Number: 3-069

Poster Title: Assessing the impact of a pharmacotherapy clinic in veteran patients with type 2 diabetes

Primary Author: Ife-atu Anachebe, University of Georgia, Georgia; **Email:** ife4848@uga.edu

Additional Author (s):
Danielle Ouellette

Purpose: Type 2 diabetes mellitus can result in increased morbidity and mortality if uncontrolled. Veteran patients with uncontrolled diabetes, hypertension, and hyperlipidemia can be referred to a pharmacotherapy clinic to have therapeutic regimens optimized and to receive more frequent follow up by a clinical pharmacist. The purpose of this study was to evaluate the impact of a clinical pharmacist on achieving favorable outcomes in diabetes, hypertension, and hyperlipidemia in an ambulatory care setting.

Methods: This retrospective chart review was determined to be institutional review board exempt as a quality improvement project. In this study, the patients' data at baseline served as the control. Inclusion criteria included a diagnosis of type 2 diabetes at baseline and enrollment in the clinic between November 1, 2015 and September 1, 2016. The exclusion criteria included a baseline hemoglobin A1c (HbA1c) of less than 8.00 percent, less than two clinic appointments, or only one HbA1c lab since the initial visit. The primary outcome measure was a change in HbA1c from baseline. Secondary outcomes included the number of patients at goal for hypertension and hyperlipidemia. Patients with diabetes were considered at goal for hypertension if the systolic blood pressure was less than 140 mmHg and the diastolic blood pressure was less than 90 mmHg. Hyperlipidemia was considered at goal if patients were on the appropriate statin therapy based on the four statin benefit groups.

Results: Out of the 88 patients who had been seen in pharmacotherapy clinic during the study period, 42 patients were excluded, leaving the final sample size to be 46 patients. The mean HbA1c at baseline was 9.64 percent, with a standard deviation of 1.64 percent. The range HbA1c at baseline was between 8.00 and 14.10 percent. At the conclusion of the study period, the mean HbA1c had decreased to 7.93 percent, with a standard deviation of 1.06 percent. The range HbA1c at the conclusion of the study period was between 6.30 and 11.10 percent. A

decrease in HbA1c was observed in 41 patients, while an increase in HbA1c was observed in four patients. One patient did not experience a change in HbA1c. For hyperlipidemia management, 35 patients were considered at goal at baseline compared to 45 patients at the conclusion of this study. For hypertension management, 36 patients were at goal at baseline compared to 42 patients at the completion of the study.

Conclusion: Patients enrolled in the clinical pharmacist-driven pharmacotherapy clinic for diabetes management had an improvement in glucose control, demonstrated by a decrease in HbA1c. Additionally, the majority of patients being followed by the pharmacotherapy clinic were at goal for hypertension and hyperlipidemia management. This suggests that clinical pharmacists at the clinic can make important contributions to chronic disease state management for diabetes, hypertension, and hyperlipidemia.

Session-Board Number: 3-070

Poster Title: Assessment of antimicrobials prescribed before and after implementation of a pharmacist-directed penicillin skin testing consult service for patients with a self-reported penicillin allergy

Primary Author: Chelsea Bryan, University of Georgia, Georgia; **Email:** cbryan8@uga.edu

Additional Author (s):
Allison Porter
Christopher Bland
Bruce Jones

Purpose: Penicillin skin testing (PST) is indicated for assessment of penicillin hypersensitivity in patients with suspected IgE-mediated penicillin allergy. Nearly 90 percent of patients with a self-reported penicillin allergy are not allergic. Successfully transitioning these patients from broad-spectrum antimicrobials to a penicillin or cephalosporin has demonstrated decreased healthcare costs and potentially decreased antimicrobial resistance. The purpose of this study is to evaluate the outcomes of a pharmacist-directed penicillin skin testing consult service.

Methods: This study is a non-randomized, observational chart review over an open enrollment period of 60 patients concurrent with prospective use of PST at a single not-for-profit community hospital. Prescribing of the test is restricted to infectious disease physicians or other clinicians pursuant to review by pharmacists from the Antimicrobial Management Program (AMP). The PST is administered by a nurse via an approved protocol and overseen by an AMP clinical pharmacist to ensure consistency in result interpretation. The protocol involves a three-step process (puncture test, intradermal test, and optional oral penicillin test) that takes approximately 45 minutes to complete. For a negative test, the AMP pharmacist makes recommendations for therapy changes with the ordering physician. Patients were excluded if they had a history of anaphylaxis in the past 10 years from beta-lactam antimicrobials or from any cause within the past 4 weeks, any condition that could interfere with test interpretation, or immunocompromised. Demographics, antimicrobial therapy before and after testing, allergy history, and results of PST were collected. The primary outcome is beta-lactam days of therapy defined as either a penicillin or cephalosporin therapy (not carbapenems). Included will be those changed from a non beta-lactam to a beta-lactam or de-escalated from broad to narrow

spectrum beta-lactam. Secondary outcomes include direct antimicrobial savings from a switch in therapy.

Results: Sixty patients were enrolled after evaluation for inclusion and exclusion criteria. Of the patients who underwent PST, 58 (96.7 percent) tested negative for penicillin allergy and 41 (68.3 percent) of those patients were changed to a beta-lactam or de-escalated in beta-lactam therapy. Due to antimicrobial changes, there was an average of 6.8 beta-lactam days of therapy for the 41 patients. In addition, 20 patients were also discharged on beta-lactams. Reasons patients were not changed from their original therapy included: extended spectrum beta-lactamase producing organism, penicillin-resistant bacteria, initiation of hospice care, and discharge immediately following the test. Two (3.3 percent) of the 60 patients had a positive PST result; one had a 9 millimeter indurated red wheal from the penicillin G intradermal test, while the other had all 4 intradermal sites positive, being at least 7 millimeters in induration. There were no adverse events that led to the discontinuation of beta-lactam therapy. Due to the changes in therapy, there was a cost savings of $18,427.26 which equates to an average cost savings of $307.12 per person.

Conclusion: This study demonstrates that pharmacist-directed PST in a community hospital results in patients receiving optimal therapy, with no adverse effects from antimicrobial changes, and reduction in cost. Not only were PST costs offset, they were far exceeded by savings. The PST results confirm that many self-reported penicillin allergies are not "true" allergies and that de-escalation of antimicrobial therapy to a beta-lactam is safe and feasible. PST can be a beneficial tool to help patients receive optimal therapy and aid in cost savings, making it a valuable antimicrobial stewardship initiative.

Poster Title: Assessment of vancomycin co-administration with anti-motility agents and toxin-binding agents in the treatment of Clostridium difficile

Primary Author: Brittany Thompson, University of Georgia, Georgia; **Email:** brittash@uga.edu

Additional Author (s):
Michelle Aw
Eareana Um
Sarah Hinton
Christopher Bland

Purpose: Clostridium difficile (C. difficile) causes symptoms ranging from multiple watery stools per day to severe colitis. The 2010 IDSA guidelines recommend oral vancomycin as a primary treatment, especially in severe disease. Some physicians prescribe bile-acid sequestrants (BAS) and anti-motility agents to attenuate C. difficile associated diarrhea. This practice is not supported by IDSA guidelines and may impede treatment by decreasing toxin elimination (anti-motility agent) or binding the vancomycin itself if given within 2 hours of dose (BAS). This study evaluates the frequency of ordering and inappropriate administration of aforementioned agents.

Methods: This Institutional Review Board-approved retrospective, observational study was performed via an electronic chart review on patients who received oral vancomycin at a community health system from August 1, 2015 to July 31, 2016. Patients who were treated for active C. difficile infection as confirmed by laboratory testing were included. A total of 229 patients were identified and reviewed for inclusion. The primary outcome measures were to assess for the presence of a BAS and/or anti-motility agent on the electronic medication administration record among patients receiving oral vancomycin for active C. difficile infection and to determine the total number of BAS administrations that occurred within 2 hours of a vancomycin dose.

Results: Of the 229 patients who received oral vancomycin, 147 patients had laboratory confirmed C. difficile. Twenty-one of the 147 patients (14%) were prescribed both oral vancomycin and a BAS. Among these 21 patients, a total of 166 doses of BAS were given. Seventy-two of the 166 doses (43%) were given incorrectly. Four of the 21 patient profiles included explicit instructions to separate the vancomycin and BAS from one another. Despite specific directions, all four of these patients received at least one dose of BAS incorrectly (6 doses total).
Twenty-one of the 147 patients were prescribed oral vancomycin and an anti-motility agent together. Sixteen of the 21 patients received at least one dose of the anti-motility agent while receiving vancomycin. Seven patients were prescribed both an anti-motility agent and a BAS, with 5 of the 7 receiving both medications.

Conclusion: The majority of the patients on oral vancomycin for active C. difficile infection were not prescribed a BAS or anti-motility agent. However, of the patients who received both oral vancomycin and a BAS, a significant number of the BAS doses were administered inappropriately, possibly increasing the risk of treatment failure. A majority of the patients who were prescribed an anti-motility agent with vancomycin received at least one dose of the anti-motility agent. Methods to decrease co-administration of BAS or anti-motility agents have the potential to improve treatment outcomes of C. difficile infections.

Poster Title: Time to first dose of antibiotics in the emergency department at an academic medical center

Primary Author: Sherriel Padua, University of Georgia, Georgia; **Email:** spadua17@uga.edu

Additional Author (s):
To-My Dinh

Purpose: Emergency department providers are challenged with limited patient information, complex disease states, and high patient turnover. Time delays in administration of antibiotics have been associated with negative outcomes. The primary objective of this study was to evaluate the mean time to first dose of antibiotics in the emergency department at an academic medical center prior to and following the opening of a satellite pharmacy. The results of this evaluation will support quality improvement initiatives that address the current limitations of the time of delivery and time of initiation of antibiotics in the emergency department.

Methods: A retrospective chart review was performed for a random sample of patients who were admitted to the emergency department and prescribed intravenous antibiotics between March 1, 2016 and August 31, 2016. This time frame included patients admitted before and after the opening of the satellite pharmacy. All patients were administered their first dose antibiotic in the emergency department. The pre-selected antibiotics included vancomycin, ciprofloxacin, piperacillin-tazobactam, and ceftriaxone. Miscellaneous antibiotics included tobramycin, gentamicin, meropenem, ertapenem, and cefepime. Data collection included type of antibiotic given, indication for antibiotic, if the patient was transferred before drug administration, and whether the medication was dispensed from the pharmacy or an automated medication dispensing cabinet located in the emergency department. Additionally, the time the order was placed by the physician, verified by the pharmacy department, and documented in the chart as given by the nurse was collected. The primary outcome measure was the mean time from order placement to administration of the first dose of antibiotics in the emergency department comparing the pre-satellite and post-satellite period. Secondary outcomes included the mean time differences based on the location of antibiotic preparation, patient transferred before drug administration, and the type of antibiotic prescribed. This

project was part of the institution's Medication Use Evaluation and Improvement Program, which has been reviewed by the Institutional Review Board and determined not to be human subjects research.

Results: Of the 100 patients analyzed, 50 patients were admitted prior to the opening of the satellite, and 50 patients were admitted following the opening of the satellite. The mean times from physician order to nurse administration for the pre-satellite and post-satellite group were 3 hours, 50 minutes and 3 hours, 32 minutes, respectively. The mean times between physician order and pharmacy verification for the pre-satellite group and post-satellite group were 28 minutes and 30 minutes, respectively. The mean times between pharmacy verification and nurse administration for the pre-satellite and post-satellite group were 4 hours, 1 minute and 3 hours, 3 minutes, respectively. During the pre-satellite period, 82 percent of antibiotics were prepared in the pharmacy and 18 percent were from the automated dispensing machine. During the post-satellite period, 62 percent were from the pharmacy and 38 percent were from the automated dispensing machine. With antibiotics prepared in the pharmacy, the mean times from physician order to nurse administration for pre-satellite and post-satellite group were 3 hours, 44 minutes and 3 hours, 31 minutes, respectively. With antibiotics from the automated dispensing machine, the mean times for pre-satellite and post-satellite group were 5 hours, 9 minutes and 3 hours, 35 minutes, respectively.

Conclusion: In this medication use evaluation, the time to first dose antibiotics in the emergency room was reduced following the opening of the satellite pharmacy. There was minimal impact on the time between physician order and pharmacy verification. However, the opening of the satellite pharmacy was associated with a decrease in time between pharmacy administration and nurse verification, as well as a decrease in time between physician order and nurse administration. Future research should be conducted to identify additional barriers and determine where implementations to improve can be made in time of first dose of antibiotics in the emergency department.

Poster Title: Risk of lactobacillus infection in critically ill adults receiving lactobacillus probiotics

Primary Author: Zachary Ruege, University of Georgia College of Pharmacy, Georgia; **Email:** zruege@uga.edu

Additional Author (s):
Andrea Newsome

Purpose: Probiotics have been advocated in critically ill patients to mitigate risk for developing Clostridium difficile infection and ventilator associated pneumonia. Critically ill patients display suppressed immune response of the intestinal mucosa and increased digestive tract permeability increasing the likelihood that probiotic bacteria may translocate into the blood and cause opportunistic infection in this population. Published case reports and case series describe lactobacillus bacteremia following administration of probiotics. The purpose of this retrospective, observational medication use evaluation is to determine the incidence of lactobacillus infections in critically ill patients that were prescribed probiotics during their intensive care unit (ICU) stay.

Methods: This study is a single-site, retrospective, non-randomized, observational medication use evaluation from January 1st 2014 and December 17th 2015. Adults greater than 18 years of age admitted to an ICU who received at least one dose of Culturelle probiotic (Lactobacillus rhamnosus GG, NDC 49100-0363-74) were included. The primary endpoint was the incidence of culture positive lactobacillus infection following probiotic administration. Secondary endpoints included both characterization of Culturelle use and clinical outcomes. Medical records were reviewed to collect information regarding patient demography, past medical history, location of care, probiotic dosing, and clinical outcomes. Descriptive statistics were performed. This study received approval from the institutional review board.

Results: A total of 99 critical care patients received at least one dose of Culturelle during the evaluation period. The population was 53.5 percent female with a mean age of 46 years old (standard deviation 29.7). Clinicians prescribed Culturelle once daily in 37.4 percent, twice daily in 60.6 percent, and three times daily in 2.0 percent of patients for a mean 22 days (standard deviation 4.95). The surgical unit admitted 37.4 percent, medical unit 43.4 percent, trauma unit

10.1 percent, and neurology unit 9.1 percent of patients for a median ICU length of stay of 32 days (standard deviation 15.6). Hospitalizations lasted for a mean 41 days (standard deviation 2.83) with a 13.1 percent in-hospital mortality. Four patients developed infections with positive cultures for Lactobacillus spp. while concurrently on Culturelle (4.04 percent). All patients with positive cultures were admitted to the surgical unit for a median 84 days ICU days with total length of hospitalization lasting a median 101 days. Of patients that received probiotics and treated in the SICU, 10.81 percent had a positive culture for Lactobacillus spp. Of those with positive cultures, there was a 50 percent in-house mortality rate.

Conclusion: A total of four patients developed infections with culture positive Lactobacillus spp. for a rate of 4.04 percent per hospitalization. All patients that had positive cultures were admitted to the surgical ICU. In 2013, Simpkins, et, al. conducted a comparable single-site retrospective review. A rate of 0.17 percent (2 out of 1176) per patient hospitalization was reported to describe risk of developing a Lactobacillus spp. related infection. This less frequent incidence may be explained because this study did not exclusively evaluate critically ill patients. The relatively high infection rate observed in critically ill, surgical patients requires further investigation.

Submission Category: Infectious Diseases

Submission Type: Evaluative Study

Session-Board Number: 3-074

Poster Title: Assessment of fluoroquinolone use for empiric treatment of urinary tract infections in a community hospital setting over a 6-month period

Primary Author: Vidhi Doshi, University of Georgia College of Pharmacy, Georgia; **Email:** vdoshi@uga.edu

Additional Author (s):
Ryne Rosberry
Whitney Smith

Purpose: To determine whether fluoroquinolones are an effective treatment option for urinary tract infections (UTIs). UTIs are widespread among patients admitted to community hospital settings where they are treated empirically with fluoroquinolones. In May of 2016, the FDA released an alert stating that fluoroquinolones should not be used in uncomplicated infections due to the disabling side effects involving tendons, muscles, joints, and nerves. In addition, Escherichia coli is the most common cause of UTIs and is developing high resistance to fluoroquinolones. For this reason, it is important to limit fluoroquinolone usage and look for safer less resistant options.

Methods: This institutional review board approved this retrospective chart review. A report of patients who had a positive urine culture and received fluoroquinolones from December 1, 2016 to May 31, 2016 was generated. This report was used to identify patients who received fluoroquinolones empirically for a suspected UTI and had a positive urine culture with culture and sensitivity data. Data was collected in a de-identified spreadsheet. The primary endpoint was the overall susceptibility of fluoroquinolones in UTIs. The secondary endpoints included overall susceptibility to fluoroquinolones stratified by health care acquired versus non-health care acquired, complicated versus uncomplicated, and pyelonephritis versus cystitis. The percent of patients in each of these groups was assessed. Other endpoints included the number of patients who were asymptomatic and the percent of the asymptomatic patients requiring treatment, the percent of each organism isolated, and the overall susceptibility to antibiotics on the panel. This was further analyzed in symptomatic patients and health care acquired versus non-health care acquired UTIs. The susceptibility of the 3 most common isolates to antibiotics on the panel was also determined. For all endpoints, if a UTI was polymicrobial, the infection

was considered susceptible if all causative pathogens were susceptible to the antibiotic. Based on the primary endpoint, a total of 126 patients were required in order to have a power of 0.8 and alpha of 0.05.

Results: 120 patients qualified for the study; therefore, power was not met. More patients were excluded than expected because several patients were not treated empirically. The overall susceptibility of fluoroquinolones used in empiric treatment of UTIs was 60.80 percent with a 95 percent confidence interval from 51.70 to 70.00 percent with a P value of 0.005 and a null hypothesis of 72 percent based upon susceptibility of Escherichia coli at Eastside Medical Center. 55.83 percent of patients were asymptomatic with only 4.48 percent of those patients requiring treatment. The common pathogens were Escherichia coli, Klebsiella pneumoniae, and Enterococcus faecalis. Fluoroquinolones were not beneficial in any subgroup. 53.25 percent of health care acquired UTIs were susceptible to fluoroquinolones. 74.42 percent of non-health care acquired UTIs were susceptible to fluoroquinolones. 56.04 percent of complicated UTIs were susceptible to fluoroquinolones. 75.86 percent of uncomplicated UTIs were susceptible to fluoroquinolones. 74.19 percent of UTIs classified as pyelonephritis were susceptible to fluoroquinolones. 56.18 percent of UTIs classified as cystitis were susceptible to fluoroquinolones. Escherichia coli had a 59.68 percent overall susceptibility to fluoroquinolones. Better empiric options include nitrofurantoin, gentamicin, cefuroxime, ceftriaxone and cefotaxime based on their spectrum and higher susceptibility rates.

Conclusion: At East Side Medical Center, fluoroquinolones are no longer an effective treatment option for UTIs. This is due to the low overall susceptibility of fluoroquinolones in UTIs and susceptibility specifically to Escherichia coli. Further support is given by the new FDA alert, which states that fluoroquinolones should be reserved for more complicated infections because of the side effect profile. Fluoroquinolones do not provide any additional benefit to the specific subgroups of UTIs. Instead, alternative empiric agents should be considered.

Session-Board Number: 3-075

Poster Title: Comparison of in-person vs. telephone anticoagulation appointments with clinical pharmacists in a Veteran's Affairs Medical Center

Primary Author: Madeline Burke, University of Georgia College of Pharmacy, Georgia; **Email:** mjb9478@uga.edu

Additional Author (s):
Marci Swanson
Deborah Hobbs

Purpose: Due to the complexities of managing warfarin therapy, pharmacists have held an increasing role in the management of anticoagulation. The purpose of this project is to determine whether pharmacist-led anticoagulation clinics are more effective in-person or by telephone. By assessing patients' current INR, goal INR, and percent time in therapeutic range (TTR), we will be able to compare whether patients are more likely to have a greater percentage of TTR within the two types of pharmacist-managed anticoagulation clinics: telephone and in-person.

Methods: This project was exempt from the Institutional Review Board. This study was completed at the Carl Vinson VA Medical Center, and it was a retrospective analysis. Veterans that had anticoagulation appointments with two clinical pharmacists either in the telephone-only or in-person clinic, between April 1, 2016 and June 30, 2016 were included. The exclusion criteria included Veterans either being bridged during the time frame or prescribed a target-specific oral anticoagulant (TSOAC). Data was collected from the Computerized Patient Record System (CPRS) and included: indication for anticoagulation, comorbidities, INR, clinic style (telephone vs. in-person), current weekly warfarin dose, time in therapeutic range, age, sex, race, and pharmacist's conclusions on reason for supra or sub therapeutic INR. Percent time in the therapeutic range was calculated for all patients with active warfarin prescriptions, diagnosis of atrial fibrillation or venous thromboembolism, and at least 3 INRs in the last 120 days. The data was de-identified and given to the author. A two-sample t-test with equal variance was used to test for statistical significance of the time in therapeutic range between the two groups. Statistical significance was defined as a $P < 0.05$ (two-tailed). All analyses were completed using Microsoft Excel.

Results: Out of 59 total screened telephone patients, 10 were excluded for taking target-specific oral anticoagulants and 49 were included in the retrospective analysis. There were 78 screened in-person patients, 26 had target-specific oral anticoagulants exclusion, 6 had bridging exclusion, and 46 were included in the retrospective analysis. The mean percent time in therapeutic range for the telephone group was 78.53% compared to the mean percent time in therapeutic range for the in-person group of 61.4%. This was a statistically significant difference (p equals 0.00142).

Conclusion: TTRs above 60% have the greatest benefit in terms of outcomes. Both clinic styles offer effective methods to reach therapeutic targets. The time in therapeutic range for telephone over in-person appointments was statistically significant. A potential explanation for this difference between groups is that Veterans with telephone appointments are more likely to be stable. Telephone appointments may be a more viable option depending on length of treatment, INR stability, and transportation needs of each patient. Future research should show if type of appointment has effect on other measures of safety and efficacy for warfarin, such as stroke or major hemorrhage.

Submission Type: Descriptive Report

Session-Board Number: 3-076

Poster Title: Analysis of legally distributed opioid consumption in the United States and selected developed countries in North America and Western Europe

Primary Author: Cori Parker, University of Georgia College of Pharmacy, Georgia; **Email:** cori.parker@uga.edu

Purpose: Opioid consumption in the United States has increased dramatically in the past twenty years, both increasing their availability for management of pain as well as increasing opportunities for misuse and diversion. Although the United States is the only country to use hydrocodone in large quantities for pain control, other developed countries are nonetheless experiencing increased consumption of pharmaceutical opioids. The objective of this research is to analyze pharmaceutical opioid consumption trends in the United States and make drug utilization comparisons with the following three countries also experiencing increased opioid consumption: Germany, Canada, and the United Kingdom.

Methods: Data from the International Narcotics Control Board (INCB) were analyzed to compare opioid utilization between the United States, Germany, Canada, and the United Kingdom. The 2014 raw annual consumption values for fifteen different opioid agents were obtained from the INCB Narcotic Drug 2015 report and then converted into defined daily doses for statistical purposes (S-DDD) that represent the daily dose, in milligrams, for a typical patient. Converting overall mass utilization into S-DDD provides a number of doses that can be compared across various opioids. All conversions for the S-DDD were obtained from the INCB Narcotic Drug 2015 report to ensure consistency. Next, these S-DDD were converted into per capita doses to account for varying country sizes, and the utilization values for the various opioids were compared. Overall consumption per capita was analyzed as well as the most commonly utilized opioids based on the INCB consumption values. The opioids included in the analysis were: buprenorphine, codeine, dihydrocodeine, ethylmorphine, hydrocodone, morphine, oxycodone, pholcodine, dextropropoxyphene, diphenoxylate, methadone, pethidine, tilidine, fentanyl, and piritramide.

Results: The 2014 annual consumption in S-DDD per million people is 52,041 for the United States, 51,491 for the United Kingdom, 32,850 for Canada, and 29,032 for Germany. Although the per capita rate of opioid consumption in the United States is highest among these countries, it is only slightly higher than the consumption rate in the United Kingdom and less than double the consumption rates in Germany and Canada. Fentanyl accounts for over half of the opioid consumption in Germany and is the primary opioid consumed in Canada, however, consumption in Canada is more evenly divided amongst other high-potency opioids and codeine. Buprenorphine accounts for nearly half of the consumption in the United Kingdom, although lower-potency opioids (codeine and dihydrocodeine) play a large role, as well. Specifically, the 2014 consumption for the United States comprises 48.1 percent hydrocodone, 13.7 percent oxycodone, 12.6 percent fentanyl and 10.5 percent methadone. The consumption for the United Kingdom comprises 46.7 percent buprenorphine and 24.5 percent codeine/dihydrocodeine. The consumption for Canada comprises 38.9 percent fentanyl, 19.6 percent methadone, 18.7 percent codeine, 11.2 percent morphine. Finally, the consumption for Germany comprises 62.2 percent fentanyl and 14.2 percent tilidine. Any opioids not listed contributed less than 10 percent.

Conclusion: While hydrocodone-containing pharmaceuticals are the most highly consumed opioids in the United States, the lack of hydrocodone utilization in other countries does not prevent these countries from having estimated per capita pharmaceutical opioid consumptions comparable to the United States. For example, while hydrocodone is not approved for pain in Canada and is not available in Germany, these countries still have opioid utilization comparable to the United States due to increased fentanyl consumption. Availability can also potentially influence utilization; codeine/dihydrocodeine are two of the most highly utilized opioids compared to other opioid alternatives in the United Kingdom and are available over-the-counter.

Poster Title: Pharmacy Student Interventions Within an Interprofessional Healthcare Team at a Free Clinic

Primary Author: Lindsey Sellers, University of Georgia College of Pharmacy, Georgia; **Email:** lsellers@uga.edu

Additional Author (s):
Macey McDaniel
Jacqueline Liu
Shaily Doshi
Catherine Bourg

Purpose: The changing healthcare environment makes it essential for healthcare professionals to work as a team while providing patient care. As a result, inter-professional education has become an integral part of the training environment for healthcare professionals. Indigent care clinics provide an excellent environment for learning to care for complex patients while also serving the underserved. The purpose of this project was to describe the patients commonly encountered at Mercy Health Center, a free clinic in Athens, GA, and to quantify the number and type of interventions made by pharmacy students while working within an interprofessional team.

Methods: The institutional review board at the University of Georgia approved this retrospective study of patients seen at Mercy Health Center during interdisciplinary clinics. Patients were seen by an interprofessional healthcare team consisting of first and second year medical students, third year pharmacy students, and a supervising attending physician. The pharmacy student role included performing medication reconciliations, making recommendations to resolve drug-related problems, and patient education. The study time period was between October 1, 2015 and April 4, 2016. The data points collected from the electronic medical record included age, gender, race, number and type of chronic conditions, and number of medications. In particular, the study looked at three common chronic conditions including diabetes mellitus, hypertension, and chronic obstructive pulmonary disease (COPD). Medication related problems were categorized by: unnecessary drug therapy, needs additional

therapy, suboptimal drug selection, dose too low, dose too high, adverse drug reaction, and nonadherence.

Results: During the study period, a total of 203 patients were seen in the Augusta University clinic at Mercy Health Center. Patients had an average of 4 chronic conditions and 5 prescription medications. The average age of patients was 50. The most common conditions encountered other than diabetes mellitus (30%), hypertension (69%), and COPD (5%) included psychiatric disorders (55%), obesity (45%), hyperlipidemia (38%), gastroesophageal reflux disorder (32%), and arthritis (18%). 50% of patients seen in clinic were Caucasian, 31% African American, and 18% were Hispanic/Latino. Over a six-month period, 69 interventions were recommended by pharmacy students for patient care at the clinic. Interventions based on medication-related problem category produced the following results: 4 inappropriate uses of medications without indication, 20 indications for pharmacotherapy but not receiving, 5 suboptimal drug selections, 9 doses too low, 6 doses too high, 11 instances of nonadherence, 3 adverse drug reactions, and 4 drug-drug/drug-food interactions. Each student made an average of 11.5 interventions, and most of these were for adding pharmacotherapy to eligible patients. Additional recommendations made by the pharmacy student team included updating the patient chart (5) and smoking cessation counseling (2).

Conclusion: These results highlight the value of including pharmacy students in an interprofessional healthcare team. The population at Mercy is particularly at risk for medication-related problems due to the high average number of comorbidities, prescription medications as well as indigent status. Inclusion of pharmacy students in the interdisciplinary team resulted in a variety of interventions. In the future, a larger sample size could be evaluated to determine the impact on hospitalization, morbidity, and cost. To optimize therapy, pharmacists should be included in the decision-making in a healthcare team.

Poster Title: Effectiveness of a student-pharmacist managed smoking cessation clinic

Primary Author: John Carr, University of Georgia College of Pharmacy, Georgia; **Email:** johncarr611@gmail.com

Additional Author (s):
Kay Brooks

Purpose: Tobacco use is a psychologically and physiologically addictive habit that has long been known to be a preventable cause of morbidity and mortality. There is an abundance of data available regarding tobacco cessation and the benefits therein, but data are limited regarding student-led tobacco cessation programs. This program was designed with a three-fold purpose: to encourage tobacco cessation in the community of Athens, Georgia; to provide a service learning opportunity for rising third year student pharmacists; and to assess the effectiveness of student pharmacists as leaders of a tobacco cessation clinic.

Methods: A six-week tobacco cessation program was implemented that focuses on a different part of the quit process each week. The University of Georgia (UGA) College of Pharmacy team modified, with permission, an existing four-session program developed by Pfizer called Beat the Pack. Modifications to the Pfizer program included the addition of two sessions, one covering pharmacological therapy and another discussing relapse prevention. In addition, forms to aid students with patient counseling and a patient education booklet with in-depth materials were added to better serve the expected patient population. This modified program combined 60-minute weekly meetings that included a brief group activity with one-on-one counseling sessions to formalize a personal quit plan. UGA pharmacy faculty acted as preceptors for third year student pharmacists, who served as the primary counselors for this service learning experience. Students were trained using education materials derived from RX for a Change, a series of educational materials developed by the University of California. Patients were counseled on both behavioral and pharmacological interventions, but the actual use of pharmacotherapy was determined ultimately by a mutual decision between the patient and the patient's primary care physician.

Results: Over the course of 6 years, the tobacco cessation program was offered a total of 10 times. In total, 80 participants enrolled in the program and 76 attended at least one meeting. There was an overall quit rate in those who attended at least one session of 48.7% (37/76). Every patient who quit tobacco attended at least 3 sessions, at which they received relevant cognitive and behavioral counseling, medication counseling, and counseling regarding the health benefits of tobacco cessation.

Conclusion: Results of this program demonstrate that properly trained student pharmacists can be effective in leading tobacco cessation programs. Appropriately designed programs can achieve quit rates that are comparable to or higher than the rates that are demonstrated by data from the 2008 HHS Treating Tobacco Use and Dependence Practice Guideline Update. This program may also serve as a model for the development of tobacco cessation programs led by student pharmacists at other locations; these programs may serve as a training opportunity for students in addition to the benefits that they provide to members of the community who use nicotine.

Poster Title: Collaboration between pharmacy and nurse practitioner students in ambulatory care advanced professional practice experiences

Primary Author: Deven Jackson, University of Georgia College of Pharmacy, Georgia; **Email:** dj1892@uga.edu

Additional Author (s):
Ashley Woodhouse

Purpose: The American Council for Pharmacy Education has established the importance of interprofessional experiences in the education of student pharmacists. At the Center for Medication Management (CMM), a pharmacist-managed clinic providing billable services, student pharmacists work closely with nurse practitioner students in many capacities including topic discussions, patient work-ups and patient presentations to practitioners. The goals of this study were to assess the perceptions of student pharmacists and nurse practitioner students regarding their collaboration in an ambulatory care setting and to highlight advanced care experiential education opportunities.

Methods: This study utilized the Student Perceptions of Interprofessional Clinical Education - Revised (SPICE-R) instrument. This validated tool aids in the assessment of health professional students' perceptions of three factors: interprofessional teamwork, roles in collaborative practice and patient outcomes as a result of collaborative practice. The SPICE-R instrument is comprised of ten items related to interprofessional education that are rated using a five-point Likert-type scale (strongly disagree to strongly agree). Nine students from the CMM anonymously responded to the SPICE-R instrument and these data were evaluated. The SPICE-R surveys were given after students had participated in rotation requirements at CMM that involved the collaboration of student nurse practitioners and student pharmacists. Rotation experiences included but were not limited to anticoagulation management, transitional care, heart failure, managed care of hypertension, hyperlipidemia or diabetes, and smoking cessation.

Results: Seven student pharmacists and two nurse practitioner students responded to the SPICE-R survey. Items related to roles and responsibilities of collaborative practice (2 and 7) received responses of "agree" or "strongly agree" from each of the nine responders. Items related to patient outcomes from collaborative practice (3 and 4) received responses of "agree" or "strongly agree" from each responder, with the exception of one pharmacy student responding with "neutral" on item 4. Items related to feelings about team-based care (1, 5, 6, and 8-10) received answers of "agree" or "strongly agree" from each responder, with the exception of one pharmacy student responding "neutral" for item 1.

Conclusion: These data reflect an overall positive perception from the students surveyed in terms of interprofessional work, roles of collaborative practice and outcomes as a result of collaborative practice in the ambulatory care setting. As colleges of higher education continue to require interdisciplinary practice, the Center for Medication Management provides an example of a collaborative advanced practice experience that serves both pharmacy and nurse practitioner students.

Poster Title: Apixaban: examining practice patterns in chronic kidney disease at Augusta University Medical Center

Primary Author: Rachel Stephens, University of Georgia College of Pharmacy, Georgia; **Email:** rastep85@uga.edu

Additional Author (s):
Christina DeRemer
Dwayne Pierce

Purpose: New target specific anticoagulants provide alternative options for anticoagulation in nonvalvular atrial fibrillation, venous thromboembolism, and post-orthopedic prophylaxis indications. However, studies eliminate patients with moderate and severe chronic kidney disease and end stage renal disease making anticoagulation in this patient population limited with regards to evidenced based literature. Currently, apixaban is the only target specific agent approved for use in chronic kidney disease and end stage renal disease. The primary objective of this study is to assess physician prescribing practices of apixaban in the chronic kidney disease population admitted to an academic medical center.

Methods: This retrospective chart review was approved by the institutional review board. Patients who are greater than 18 years of age, had an active order for apixaban during hospitalization, had diagnosed chronic kidney disease or a serum creatinine greater than 1.5 mg/dL during the admission were included in this study. Patient records were identified by a targeted drug report using the Cerner discern analytic system to identify all patients who received at least one dose of apixaban in the emergency department or during a hospital stay between the dates of March 3, 2014 to March 3, 2016. Patients were excluded if they did not meet all of inclusion criteria. The primary outcome of the study was to evaluate the physician prescribing practices of apixaban in the chronic kidney disease population by evaluating the indication, dosing, and baseline stroke and bleeding risks. Secondary outcomes included rates of recurrent thrombosis, bleeding, and any barriers of compliance. Since the goal of this study is to evaluate all patients meeting the inclusion criteria, no power analysis was performed.

Results: A total of 572 patients received at least one dose of apixaban between March 3, 2014 and March 3, 2016. Of the 572, 181 patients met the inclusion criteria and were analyzed. Of the patients analyzed, 92 were female, 101 were Caucasian, with an average age of 67.3 years. The most frequent indication for anticoagulation was non-valvular atrial fibrillation where n equals 130. Twenty-six patients were prescribed apixaban for off-label indications such as arterial and graft thrombus. One hundred and sixteen patients were dosed with 5 mg twice daily of apixaban. Based on approved renal dosing indications, 143 patients were prescribed the appropriate dose of apixaban based on renal dosing criteria.The average CHADs-VAsC2 score was 2.5 and the average HAS-BLED score was 2.1. Eight patients experienced a thrombus and 18 patients experienced a bleed within 1 year of taking apixaban with the most common source of bleeding being a gastrointestinal bleed where n equals 10. Of the 26 patients on apixaban for an off-label indication, 5 experienced an adverse event with 4 of the 5 patients having a thrombus.

Conclusion: With apixaban being the only target specific anticoagulant agent with an indication in renal impairment, many prescribers select it in chronic kidney disease and end stage renal disease. The evaluation of apixaban prescribing at Augusta University Medical Center indicates that patients are being prescribed apixaban appropriately based on indication and renal dosing. Comparing bleeding events from the ARISTOTLE trial to this study shows a greater percentage of bleeding events in patients with chronic kidney disease and end stage renal disease, however it would be appropriate to follow patients for longer than one year to see if this trend continues.

Poster Title: Evaluation of elevated international normalized ratios in hospitalized patients taking warfarin: a retrospective chart review

Primary Author: Shaily Doshi, University of Georgia College of Pharmacy, Georgia; **Email:** shaily12@uga.edu

Additional Author (s):
Christina DeRemer

Purpose: The use of warfarin as an antithrombotic agent is challenging because of its narrow therapeutic International Normalized Ratio (INR) range and numerous interactions. Clinical studies and observations have shown increased risk of bleeding with INR above 3 and need for reversal in INR above 5 but few studies have been done to determine the causality of elevated INRs in hospitalized patients taking warfarin. The primary objective of this medication use evaluation (MUE) is to determine the causality of elevated INR above 5 in hospitalized patients at an academic medical center.

Methods: A retrospective chart review was performed at Augusta University Medical Center in Augusta, Georgia, between June 2015 and July 2016, on hospitalized patients taking warfarin who had INR values above 5. Data collection included patient demographics, warfarin indication, and INR goal. Details regarding origins of warfarin initiation were also collected. Other data points gathered included known interacting medications with warfarin, disease states affecting INR such as liver damage or congestive heart failure (CHF) exacerbation, warfarin dose, and others (e.g. noncompliance, heparin induced thrombocytopenia, malnutrition, or chronic diarrhea). Descriptive statistics will be used to analyze this data which was collected on a de identified excel spreadsheet. This project was approved by the Augusta University institutional review board as a "not human subject research". It is also a part of the health system MUE and improvement program.

Results: A total of 130 patients were evaluated with an average age of 65 years consisting of 57 male patients. Forty three percent of patients were African American, 55 percent Caucasian, and 2 percent Hispanic. The most common indications for being on warfarin therapy were deep vein thrombosis at 21.3 percent, pulmonary embolism at 20.5 percent and atrial fibrillation at

37.7 percent. Overall, 47.5 percent of patients were admitted with INRs greater than 5. Elevations that occurred after hospitalizations occurred in 52.5 percent of patients of which 19 patients were newly initiated on warfarin in the hospital and 45 patients were continued from outpatient. Out of all INR elevation, 59 percent were associated with use of interacting medications; mainly consisting of antibiotics and antiarrhythmic. Thirty one patients out of the 45 patients admitted with a therapeutic INR experienced an elevation in INR during hospitalization due to drug interactions. Other common causes in these patients were CHF exacerbation and liver damage defined from the clinical notes as well as change in dietary intake.

Conclusion: Supratherapeutic INRs are a concerning problem in hospitalized patients. Especially concerning are those that were admitted with therapeutic INRs and due to drug interactions resulted in an elevated INR greater than 5. Since interacting medications were a leading cause of INR elevation, it is important to take extra precautions when administering medications to patients on warfarin. Based on these results, a protocol on medication administration in patients on warfarin may be preventative. Other future directions may include development of electronic resources for screening or high risk interaction identification.

Poster Title: Evaluating the use of a Candida panel

Primary Author: Paige Wallace, University of Georgia College of Pharmacy, Georgia; **Email:** pwallace@uga.edu

Additional Author (s):
Emily Murray
Sonal Patel
Jere May

Purpose: Early identification of pathogens is essential to assure patients are receiving optimal therapy as early as possible. The goal of the Candida panel, implemented in April 2016, is to be able to quickly detect if patients have invasive candidiasis. These results, available within 3 to 5 hours, allows for antifungal stewardship. The goal of this study is to evaluate the use of the Candida panel by monitoring adherence to the candidiasis algorithm, a prompt start of antifungal therapy in those with positive results, and quick discontinuation of antifungal in those with a negative result.

Methods: Our institutional review board approved this retrospective study. Our microbiology lab generated a list of patients with orders for the Candida panel. All patients listed were included in the study. Patients' medical records were reviewed for the following information: service that ordered the test, results of the test, and if the Candida panel algorithm was followed. The algorithm starts with patients being on broad-spectrum antibiotic coverage for greater than or equal to 72 hours and still febrile or showing signs of clinical deterioration. These patients must also have presumptive candidiasis, defined by a Candida score greater than or equal to three (one point for the following: total parental nutrition, surgery on intensive care unit admission, multifocal Candida colonization and two points for severe sepsis). If the test results were negative, charts were evaluated to determine what antifungal therapy was prescribed, when it was prescribed, and when it was discontinued. Patients whose test was positive, evaluation was done to see how long before antifungal therapy was started and which agent was chosen. Additionally, medical records were reviewed to determine if antifungal therapy was started before or after the test was drawn and how many hours before or after the

test was drawn was the therapy started. The data was placed into an Excel spreadsheet to determine trends and if the Candida panel is being used properly.

Results: One hundred and thirty three patients were included in this study. Of these, only 23 percent followed the algorithm for ordering the Candida panel. Seventy-one percent of patients not following the algorithm did not have presumptive candidiasis (i.e. algorithm score less than three) making this the most common reason for improper use of the test. Additional reasons included, 44 percent of patients being on antifungal therapy prior to ordering the test, or 7 percent not being on empiric antimicrobial therapy for 72 hours. However, of the 103 patients who did not follow the algorithm, 17 percent of the tests were ordered per recommendations by the Infectious Disease team. Only 5 of the 133 test had positive results, all for Candida albicans/ Candida tropicalis. For those with negative tests, only 52 percent discontinued antifungal therapy, taking an average of 41 hours to discontinue therapy ranging from 1 to 146 hours. Twenty-five patients started on antifungal therapy at the time the Candida panel was ordered which is consistent with the algorithm. Of all the patients on antifungal therapy either before or after the test was ordered, 51 percent were on micafungin, an infectious disease approved drug, and 47 percent were on fluconazole.

Conclusion: The newly implemented Candida panel has not been integrated into therapy as intended. The benefit of the test is to prevent patients from being placed on antifungals when it is unnecessary. Currently the majority of patients receiving the test are still taking unnecessary antifungal therapy. This creates risk for antifungal resistant organisms and added expense to the patient and hospital. Further education needs to be done involving appropriate patient choice, not starting antifungals until Candida panel is ordered, and promptly discontinuing antifungals if a negative result is received.

Poster Title: Risk Factors for Hypoglycemia in a 200 Bed Community Hospital

Primary Author: Heari Yu, University of Georgia College of Pharmacy, Georgia; **Email:** yuheari@uga.edu

Additional Author (s):
Robin Southwood

Purpose: Hypoglycemia is the most common and major adverse event associated with the treatment of inpatient hyperglycemia. Hypoglycemia has had a significant negative impact on healthcare costs, resources, and patient outcomes (increased risk of cardiac events and mortality). This study will describe factors associated with hypoglycemia in a 200 bed community hospital and should provide insight concerning inpatient hypoglycemia, which could allow for opportunities of improvements in patient care.

Methods: This study is a single-center, retrospective, chart review. It includes patients admitted to St. Mary's Hospital from March 1, 2016 to July 30, 2016 who experience hypoglycemia (< 70 mg/dL) associated with drug therapy and are of age equal to or greater than 18 years old. Exclusion criteria includes treatment and discharge from emergency department, hypoglycemia unrelated to use of drug therapy, and pregnancy. Patient health information such as age, A1c, serum creatinine, creatinine clearance, BMI, and drug therapy will be utilized to help identify factors associated with hypoglycemia.

Results: 115 individuals met the criteria of this study. The average age of patients who experienced hypoglycemia was 63.9, where 53 percent of hypoglycemic patients were over the age of 65. 41.7 percent of patients had a A1c value greater than 8 percent, which is not at goal (less than or equal to 8 percent or 7 percent based on patient specific characteristics) per ADA guidelines. 45.2 percent of hypoglycemic patients were obese (BMI >30) and 27 percent of hypoglycemic patients were overweight (BMI 25-29.9), which equates to 72.2 percent of patients having a BMI of at least 25. 66.1 percent of patients were on long acting basal insulin, while 78.3 percent were on sliding scale insulin.

Conclusion: Type 2 diabetics who experienced inpatient hypoglycemia were more likely to be older, have higher A1c values (not at goal), higher BMI, and be on some sort of insulin therapy. Patients admitted with these characteristics warrant close monitoring for the development of hypoglycemia. The sample size for type 1 diabetics was too small to draw conclusions.

Poster Title: Impact of hospital software on reporting to a state vaccine registry

Primary Author: Hanna Park, University of Georgia College of Pharmacy, Georgia; **Email:** xhpark@uga.edu

Additional Author (s):
Melody Sheffield
Rod Gilmore

Purpose: Reporting accurate and complete vaccination information by immunization providers is critical. It helps identify patients needing vaccinations and aids surveillance programs. In October 2015, Phoebe Putney Memorial Hospital (PPMH) in Albany, Georgia adopted a new software, Meditech, to manage all PPMH patients' health and services information. The primary outcome was to determine if implementation of Meditech has made a difference in the reporting of adult influenza vaccinations to a state vaccine registry, Georgia Registry of Immunization Transactions and Services (GRITS). The secondary outcome was to evaluate the percentage of patients who received flu vaccines and had a high risk comorbidity.

Methods: The University of Georgia institutional review board approved this retrospective review. The retrospective review was conducted on PPMH inpatients and outpatients who received adult influenza vaccines in November 2014 and November 2015. No identifiable subject information was maintained. PPMH Information Systems Department ran a report of all patients whom adult influenza vaccine was ordered and/or dispensed in November 2014 and 2015. Patients less than 18 years old were excluded. From the remaining patients on the list, all patients were reviewed to identify who received the vaccine at the facility, and then further reviewed for documentation in GRITS until 100 patients who received the vaccine had been selected for review in each time period. The included patients were assigned a research number as in 1114001, 1114002, 1114003, etc...for the November 2014 group and 1115001, 1115002, 1115003, etc... for the November 2015 group. The investigators verified whether influenza vaccine administration was documented in GRITS (Yes/No) for the included subjects. The number of patients who did not actually receive the vaccine was compared to the number for whom the vaccine was ordered. Additionally, the investigators collected and evaluated included subjects' age, sex (Male/Female), and presence of following comorbidities: diabetes

mellitus (DM), heart failure (HF), stroke, end stage renal disease (ESRD), liver disease, chronic obstructive pulmonary disease (COPD), and asthma (1 for presence and 0 for absence).

Results: In November 2014, 100 patients received the adult influenza vaccine out of 148 patients for whom vaccine was dispensed; 37 percent were male and 63 percent were female. Out of the 100 patients, 24 percent had DM, 8 percent HF, 6 percent ESRD, 1 percent liver disease, 11 percent COPD, 8 percent asthma, and zero stroke. In November 2015, only 64 patients received the adult influenza vaccine out of 230 patients for whom vaccine was ordered; 50 percent were male and 50 percent were female. Out of the 64 patients, 31 percent had DM, 18 percent HF, 12 percent stroke, 14 percent ESRD, 6 percent liver disease, 17 percent COPD, and 4 percent asthma. In 2014, 2 vaccine administrations (2 percent) were documented in GRITS, and 11 documentations (17 percent) were documented in November 2015. The p-value was 0.0004 using the chi-square statistic test with one degree of freedom and the significance level set at 0.05.

Conclusion: Implementation of a new software, Meditech, at PPMH has made a significant difference in reporting of adult influenza vaccinations to the state vaccine registry, GRITS. However, the number of reporting to GRITS remains low compared to the number of vaccinations administered. Healthcare providers should be continuously encouraged to report in a timely manner.

Poster Title: Cryptococcal meningitis in an immunocompetent patient: Case Report

Primary Author: Taylor Smith, University of Georgia College of Pharmacy, Georgia; **Email:** taylorzsmith@yahoo.com

Additional Author (s):
Memorie Wilcoxon

Purpose: Cryptococcus is a common fungus that is found throughout the environment, specifically soil. In healthy, immunocompetent patients, ingestion of these spores does not typically cause a problem. However, in immunocompromised patients, such as those with HIV/AIDS or organ transplants, this opportunistic infection can cause serious disease. Cryptococcal meningitis occurs when the infection spreads from the lungs to the brain and spinal cord. Although we have effective antifungal treatment, it has a high morbidity and mortality rate globally due to the poor availability of fungicidal drugs in developing countries. A 26-year-old Vietnamese male, who recently immigrated to the United States, was brought to the emergency department for transient unresponsiveness and generalized weakness. He was previously healthy until 3 weeks prior when he developed a gastrointestinal illness with nausea and vomiting. He was initially treated for Helicobacter pylori but was unable to tolerate the quadruple therapy regimen. When he presented to the ED, he had been experiencing myalgias, weakness, poor sleep and appetite, significant headaches, left eye blurry vision and double vision, right arm numbness and a 13 pound weight loss over 3 weeks. Initial laboratory results included a white blood count of 16.4, potassium of 3.1, C-reactive protein less than 0.3, CT scan of the head was negative and blood cultures were positive for Cryptococcus neoformans, an encapsulated yeast associated with aged pigeon droppings. The patient's HIV test was negative, cryptococcal antigen in both the serum and cerebrospinal fluid (CSF) was greater than 2000, and CSF Epstein-Barr virus DNA was positive for 1,100 copies. He was started on high dose liposomal amphotericin and 5-fluocytosine. Per the IDSA cryptococcal guidelines in an HIV negative patient with neurologic complications, the patient would need 6 weeks of induction therapy. The patient's increased intraocular pressure (IOP) caused papilledema, lateral rectus palsy and blurred vision. A lumbar puncture was performed daily to monitor the open pressure with a goal of less than 25cm. The IOP remained high, requiring the placement of a lumbar drain, which remained in place for 10 days. On Day 23, the lumbar puncture revealed an

increased IOP of 65cm and a new lumbar drain was placed. The lumbar drain was insufficient in keeping the pressure down so a ventriculoperitoneal (VP) shunt was placed on Day 31.The patient had persistent hypokalemia and hypercalcemia due to the drug therapy, requiring constant monitoring and replacement of electrolytes. Due to the high cost of amphotericin and 5-fluocytosine, the patient was discharged after 37 days in the hospital on oral fluconazole. The patient returned to the hospital 2 weeks later with worsening ataxia, evidence of advancing cryotpcoccus and treatment failure. Amphotericin B was restarted and fluconazole was changed to posaconazole and the patient began treatment for tuberculosis, despite no active symptoms, only a positive QuantiFERON Gold test. The patient was discharged to a rehab center on oral posaconazole and a steroid taper. At this point, the patient had completed his second induction with amphotericin. After 20 days in rehab, the patient presented to the ED with recurrence of symptoms (tachycardia, nausea, abdominal discomfort, headache, fever and leukocytosis). The VP shunt was removed due to a CSF culture positive for gram-negative bacteria. The patient was treated with a 21-day course of Merrem for pseudomonal meningitis, associated with the VP shunt and currently remains on posaconazole indefinitely. As this case suggests, the patient may have some underlying immune dysfunction that is aiding in the treatment failure of the cryptococcal meningitis. Further research and evaluation would be beneficial to examine a potential link between cryptococcal meningitis and Epstein-Barr virus.

Poster Title: Assessment of therapeutic duplication for inpatients prescribed as needed medications for the treatment of constipation at an academic medical center

Primary Author: Allyson Cox, University of Georgia College of Pharmacy, Georgia; **Email:** aacox@uga.edu

Additional Author (s):
Stephanie Lively

Purpose: The Joint Commission Medication Management Standards require that medication orders are clear and accurate. Furthermore, medication orders must be reviewed by a pharmacist and assessed for therapeutic duplication, which is defined by this academic medical center as prescribing or using multiple medications for the same indication without accompanying clarification. Clarification may include directions for use for specific symptoms, instructions for the sequence of administration or a statement that the use is appropriate given different mechanisms of action. The primary objective of this study was to evaluate the prevalence of therapeutic duplication of as needed medications for the treatment of constipation.

Methods: A retrospective chart review was conducted for a random sample of patients admitted from January 1, 2016 to June 30, 2016 who were prescribed two or more pre-specified as needed medications for the treatment of constipation. Such medications included bisacodyl, docusate, lactulose, polyethylene glycol and senna. Data collection included patient location and hospital service, name and dosage of the medications ordered, dosing intervals, indication and presence of order comments or instructions regarding the sequence of administration. If qualifiers were included in the order comments of every medication order, the use of multiple medications was considered appropriate. However, if the order comments for one or more of the medication orders lacked clarification, the use of multiple medications was considered inappropriate. Inappropriate therapeutic duplication was further stratified into orders that were partially clarified (i.e., instructions for administration were included in one but not all of the medication order comments) and not clarified (i.e., no instructions for use within the medication order comments). Descriptive statistics were used to analyze the data. This project was part of the institution's Medication Use Evaluation and Improvement Program,

which has been reviewed by the Institutional Review Board and determined not to be human subject research.

Results: 129 patient encounters were evaluated for therapeutic duplication of medications prescribed as needed for the treatment of constipation. The average number of as needed orders for the treatment of constipation was 2.5 medications. 84 percent of patient encounters included two active medication orders prescribed as needed for the treatment of constipation, 13 percent of patient encounters included three active medication orders and 3 percent of patient encounters included four active medication orders. No encounters had more than 4 as needed medications for the treatment of constipation. The use of multiple medications was considered inappropriate in 100 percent of the patient encounters evaluated. Only 2 percent of patient encounters included medication orders that were partially clarified. The most common medications prescribed were bisacodyl, senna and docusate. The most common locations of therapeutic duplication were adult medicine, emergency services, trauma and progressive care and adult intensive care units.

Conclusion: Given the results of this medication use evaluation, it is important to develop policies and protocols addressing therapeutic duplication, implement modifications to computerized prescriber order entry, and provide education to staff. Although the prescribing and use of multiple medications for the treatment of constipation may be appropriate due to unique and differing mechanisms of action, it is still essential to define the circumstances for administration to prevent misinterpretation and optimize patient care.

Submission Type: Evaluative Study

Session-Board Number: 3-087

Poster Title: Evaluation of acetaminophen dosing at an academic medical center.

Primary Author: Courtlyn Smith, University of Georgia College of Pharmacy, Georgia; **Email:** courtlyn@uga.edu

Additional Author (s):
Marjorie Phillips
Tom Flynt

Purpose: Acetaminophen is frequently used in the hospital as an antipyretic and analgesic. However, excessive use of acetaminophen poses a risk for hepatotoxicity that could ultimately result in death or need for a liver transplant. In order to limit potential for liver damage, the FDA recommends a maximum dose limit of 4,000 milligrams per 24 hours for an adult. For pediatric patients or adults weighing less than 50 kilograms, the maximum daily dose is 75 milligrams per kilogram per day. The purpose of this retrospective evaluation is to assess consistency in not exceeding the maximum recommended daily dose of acetaminophen.

Methods: This project is part of the Medication Use Evaluation (MUE) and Improvement Program, which has been reviewed by the IRB and determined not to be human subject research. A retrospective review was performed on a random sample of one hundred patients who received acetaminophen-containing products at least once during the time period of August 17- August 24, 2016. Evaluation parameters included the acetaminophen product the patient received, the potential dose of medication that the patient could have received in 24 hours, and the actual dose of medication that the patient did receive in 24 hours. Total doses given within 24 hours were calculated to include all scheduled, as needed, and one time doses of acetaminophen during the time period. This review also evaluated concurrent use of more than one acetaminophen- containing product, including oxycodone-acetaminophen, hydrocodone- acetaminophen, and intravenous acetaminophen.

Results: In adults weighing 50 kilograms or more, 67 percent (46/68) did not have the potential to receive greater than 4 grams of acetaminophen in 24 hours with two patients actually receiving more than 4 grams. Of the adult patients weighing less than 50 kilograms, 66 percent (2/3) did not have the potential to receive greater than 75 milligrams per kilogram per day and

one patient exceeded the maximum dose. In the pediatric patient sample, 79 percent (23/29) did not have the potential to receive greater than 75 milligrams per kilogram per 24 hours with 2 patients receiving a dose greater than that upper limit.

Conclusion: Continued improvement is needed on the part of both physicians and pharmacists to ensure that orders are not written and verified that could allow a patient to receive greater than the recommended daily acetaminophen dose. Increased pharmacist involvement in this process could decrease the opportunity for error and improve patient safety. As the medical center is currently considering removing intravenous acetaminophen from formulary, the information from this medication use evaluation may support this decision. The Pharmacy and Therapeutics Committee will meet and discuss the next steps regarding the optimal and safe use of acetaminophen products.

Submission Type: Evaluative Study

Session-Board Number: 3-088

Poster Title: Extended-Interval Aminoglycoside Dosing in Pediatric Patients with Cystic Fibrosis Exacerbations

Primary Author: Shannon Alexander, University of Georgia College of Pharmacy, Georgia;
Email: shannona@uga.edu

Additional Author (s):
Kalen Manasco

Purpose: Optimal dosing of aminoglycoside antibiotics in pediatric cystic fibrosis (CF) patients has long been debated. Arguments have been made in favor of traditional multiple daily dosing (MDD) as well as extended-interval, or once daily dosing (ODD). The Cystic Fibrosis Foundation endorses and recommends extended-interval dosing. ODD of aminoglycosides has concentration-dependent bactericidal activity, less drug accumulation that causes renal and vestibular toxicity, a post-antibiotic effect, and decreased risk of adaptive resistance. The purpose of this study was to determine if ODD of aminoglycosides in pediatric CF exacerbation patients reached and maintained therapeutic serum drug concentrations.

Methods: Pediatric patients (defined as 18 years or younger upon admission) who were admitted for CF exacerbations between September 2015 and September 2016 and received ODD of an aminoglycoside were included in this evaluation. ODD is recommended in ages 5 years and older, so patients under 5 years were excluded. Patients meeting inclusion criteria received extended-interval dosing of tobramycin, the aminoglycoside of choice per institution-specific susceptibilities. Patients were started on a dose of 10 mg/kg administered intravenously once daily. If a patient had previous admission(s) with tobramycin treatment, they were started at the dose that was last found to achieve therapeutic serum drug levels. Levels were drawn 3 hours and 12 hours after the start of the second dose. Therapeutic serum drug levels were defined as those giving a calculated 30-minute post-dose peak of 8-10 times the MIC of the suspected organism(s) (based on institution antibiogram and/or patient history of susceptibility) and a calculated trough of < 2 mcg/ml. The primary endpoint of this evaluation was the percent of patients who achieved therapeutic drug levels with initial dose selection. Secondary endpoints included the number of dose adjustments required to achieve therapeutic

drug levels in patients who did not reach it initially. The institutional review board approved this retrospective drug-use evaluation.

Results: The evaluation population included 23 total patients (n equals 23). This population included 11 females and 12 males ranging from 6 to 18 years of age (average 11.5 years). Of the 23 patients included in this evaluation, 16 patients (70 percent) achieved therapeutic serum drug levels using initial dosing strategies. Of the 7 patients who were found to be outside of the therapeutic range, 6 were subtherapeutic and 1 was supratherapeutic. Of these 7 patients, 2 required 3 dose adjustments and 5 required only 1 dose adjustment to achieve therapeutic levels.

Conclusion: Extended-interval dosing of aminoglycoside antibiotics achieved therapeutic serum drug levels in the majority pediatric cystic fibrosis patients admitted for CF exacerbations requiring antibiotic treatment. Furthermore, the majority of patients who do not achieve therapeutic levels with initial dosing strategies only required one dose adjustment to be within the therapeutic range. This evaluation supports once daily or extended-interval dosing of aminoglycosides in this patient population, and shows that it can be a reliable and efficacious approach to treatment.

Poster Title: Evaluation of antipsychotic prescribing and monitoring for geriatric patients in a long-term care facility for veterans

Primary Author: Katherine Donnan, University of Georgia College of Pharmacy, Georgia; **Email:** kmsmith8@uga.edu

Additional Author (s):
Katie Ferguson
Kevin Corbin

Purpose: Antipsychotics are utilized in the geriatric population to treat psychosis associated with multiple disease states, including schizophrenia, bipolar disorder, and dementia. The FDA has issued a black box warning for all antipsychotics for increased mortality in elderly patients with dementia-related psychosis. Therefore, the Centers for Medicare and Medicaid Services (CMS) has published regulations concerning the appropriate use and monitoring of antipsychotics for the elderly in long-term care facilities. The purpose of this study was to assess compliance with these standards at a long-term care facility for veterans.

Methods: This was a retrospective chart review which evaluated all residents of a long-term care facility who had been treated with any antipsychotic agent between July 2015 and June 2016. Patient charts were reviewed for proper indications, monitoring parameters, and attempts at dose reduction. Proper indications included schizophrenia, mania, depression with psychotic features, adjunct use with antidepressants, psychosis, Tourette's disorder, Huntington's disease, and dementia, delirium, amnestic or other cognitive disorders with associated psychotic behaviors. Monitoring parameters included daily behavioral record, annual abnormal involuntary movement scale (AIMS) assessment, fasting plasma glucose, fasting lipid panel, blood pressure, and quarterly body weight.

Results: Out of 161 residents of the long-term care facility, 42 had taken an antipsychotic in the period from July 2015 to June 2016. One hundred percent of patients had an indication documented in the patient chart that was appropriate for antipsychotic use. All had received annual monitoring of AIMS, blood pressure, and fasting blood glucose, as well as quarterly monitoring of weight. One patient did not have a daily behavioral record. Eighty one percent

(34 of 42) had an order for a fasting lipid panel at least annually. Almost half of the patients (20 of 42) were not eligible for dose reduction due to one of the following reasons: documentation of ineligibility in the active problem list or start of an antipsychotic within the past 6 months. Of the remaining 22 patients who were eligible, seventy three percent (16 of 22) had at least one dose reduction within the past year. Of the six patients who did not, two had a recent dose increase and four were eligible for reduction.

Conclusion: Indications for antipsychotic use were consistent with current CMS regulations. Monitoring parameters were measured appropriately, with the exception of yearly fasting lipid panel. While proper dose reduction or documentation of ineligibility were noted in the majority of patients, emphasis should be placed on verification of dose reduction or ineligibility by a pharmacist during monthly medication reviews, as well as education for prescribers on CMS dose reduction regulations.

Poster Title: Evaluation of therapeutic duplication for inpatients prescribed multiple as needed medications for the treatment of nausea and vomiting at an academic medical center

Primary Author: William Ellisor, University of Georgia College of Pharmacy, Georgia; **Email:** we1011@uga.edu

Additional Author (s):
Jaimie Bailey
Stephanie Lively

Purpose: Compliance with the Joint Commission Medication Management Standards requires all medication orders to be clear and accurate. Additionally, medication orders must be assessed by a pharmacist for therapeutic duplication among other characteristics indicating appropriateness. Therapeutic duplication is defined by this academic medical center as the prescribing or use of multiple medications for the same indication without clarification, which may include the sequence of administration. The objectives of this study were to evaluate the prescribing practices of as needed medications for the treatment of nausea and vomiting and to determine if appropriate instructions were included within the medication orders.

Methods: A retrospective chart review was conducted of a random sample of patients admitted to the academic medical center from January 1, 2016 to June 30, 2016 who were prescribed two or more pre-specified as needed medications for the treatment of nausea and vomiting. These medications included ondansetron, metoclopramide, prochlorperazine, promethazine, lorazepam and diphenhydramine. Data collection included patient location, name and dosage of the medications ordered, dosing interval, indication and presence of order comments or instructions regarding the sequence of administration. The use of multiple medications was considered appropriate if all medication orders contained clarification or qualifiers within the order comments. In contrast, the use of multiple medications was considered inappropriate if the order comments for one or more medication orders lacked explanation. Inappropriate therapeutic duplication was further stratified into orders that were partially clarified (i.e., instructions for administration were included in one but not all of the medication order comments) and not clarified (i.e., no instructions for use within the medication order comments). Descriptive statistics were used to analyze the data. This project

is part of the institution's Medication Use Evaluation and Improvement Program, which has been reviewed by the Institutional Review Board and determined not to be human subject research.

Results: 253 patient encounters associated with 560 as needed medication orders were reviewed for therapeutic duplication. The use of multiple medications was considered appropriate in 4 percent of patient encounters. 96 percent of patient encounters included orders identified as inappropriate duplicate therapy due to a lack of clarification. Of the patient encounters with unclarified orders, 35 percent of encounters had partially clarified orders with instructions for one of the medications, and 65 percent of encounters had no clarification. With regard to inappropriate therapeutic duplication, 82 percent of encounters included two duplicate medications, 15 percent of encounters included three duplicate medications and 3 percent of encounters included four duplicate medications. In the instances of duplicate therapy for the treatment of nausea and vomiting, the most common medications prescribed were promethazine, ondansetron and prochlorperazine. 66 percent of patient encounters with unclarified orders included both promethazine and ondansetron. The most common locations of unclarified orders were emergency services, adult medicine and adult intensive care units.

Conclusion: The prescribing and use of multiple as needed medications for nausea and vomiting without instructions for administration may cause nursing confusion and increase the risk for medication errors and adverse drug events. In this medication use evaluation, appropriate clarification was lacking in a vast majority of instances where multiple as needed medications for nausea and vomiting were prescribed. The results of this study demonstrate a need for policy and protocol development, computerized prescriber order entry revision and staff education.

Submission Category: Ambulatory Care

Submission Type: Evaluative Study

Session-Board Number: 3-091

Poster Title: Evaluation of medical student perceptions of interprofessional educational experiences alongside pharmacy students in an indigent care, ambulatory clinic.

Primary Author: Amanda Hughes, University of Georgia College of Pharmacy, Georgia; **Email:** aph210@uga.edu

Additional Author (s):
Megan Cox
Catherine Bourg

Purpose: The study objective was to examine medical student perceptions of interprofessional education while collaborating with pharmacy students in health care teams at Mercy Health Center, an ambulatory care clinic. This included how interprofessional teamwork influenced their education and overall perception of patient care. Additionally, the study evaluated how the students' viewpoints changed throughout the duration of the program.

Methods: The data was collected using a qualitative survey known as the Student Perceptions of Physician-Pharmacist Interprofessional Clinical Education (SPICE) instrument. It was completed by medical students through secure University of Georgia Qualtrics software for web-based surveys. The inclusion criteria was first and second year medical students enrolled at the University of Georgia campus Medical College of Georgia who volunteered at Mercy Health Center at least once throughout data collection period. The IRB was amended to allow for an expanded sample of medical students. Second year medical student clinic managers and pharmacy students assisted in survey distribution. Pharmacy students also promoted the survey at clinics and had both computer and paper copies of the survey available for medical students to complete. Prior to beginning the survey, participants were provided a consent letter and were required to give informed consent in order to continue on to the survey. All data was anonymously collected between December 2014 to May 2016. Results were analyzed and compared to findings from the previous year.

Results: Over the course of two years, 50 medical students completed the survey. Twenty students completed the survey the first year, while 30 completed it the second year. Only 5 students participated in the survey both years. The percentage of students who either agreed or strongly agreed that working with a pharmacy student enhanced their education increased from 68 percent to 84 percent over the two years. 93 percent of students the first year and 82 percent the second year agreed or strongly agreed that health outcomes for the patient were improved by having a team filled with people of multiple disciplines. 75 percent of students the first year and 92 percent the second year agreed or strongly agreed that people within the healthcare profession should be educated in how to establish collaborative relationships with members from other disciplines. 75 percent of students the first year and 93 percent the second year agreed or strongly agreed that physicians and pharmacists should collaborate in teams.

Conclusion: The majority of the medical students who volunteered at Mercy Health Center and had the opportunity to work in a collaborative healthcare team believed that it was beneficial. They felt that it improved their own education as well as improved overall patient outcomes. Perceptions of interprofessional teams improved over the course of two years of survey distribution. Our data suggests that medical students desire to collaborate with pharmacy students in the free clinic setting. Future directions include further evaluation of the interprofessional program and the impact on patient outcomes.

Poster Title: Incidence of acute kidney injury with concomitant vancomycin and piperacillin/tazobactam use in pediatric patients

Primary Author: Haley Woods, University of Georgia College of Pharmacy, Georgia; **Email:** haleywoods92@gmail.com

Additional Author (s):
Anita Gallay

Purpose: Vancomycin and piperacillin/tazobactam are two antibiotics that are commonly used due to a broad spectrum of activity when used together. However, both medications are independently associated with nephrotoxicity. There are reports demonstrating increased rates of acute kidney injury (AKI) in adults receiving both medications, there are few reports exploring this topic in pediatric patients. The purpose is to assess the incidence of AKI in pediatric patients who receive concomitant vancomycin and piperacillin/tazobactam therapy, and to examine four different criteria to determine a correlation to AKI: dose of vancomycin, dose of piperacillin/tazobactam, receiving other potentially nephrotoxic drugs, and duration of therapy.

Methods: This retrospective study received data from patients admitted to Children's Hospital of Georgia from January 1, 2014 to September 15, 2016. Patients from birth to 18 years of age were included if they received vancomycin and piperacillin/tazobactam simultaneously. Patients were excluded if they demonstrated baseline renal insufficiency (defined as an increase in serum creatinine by at least 50 percent, an absolute increase in serum creatinine by at least 0.3 mg/dL, or a baseline creatinine clearance of less than 60 mL/min), have documented renal injury or disease, or are receiving dialysis. Data collected from the electronic medical record included a medical record number, floor, date of birth, age, sex, weight, height, race, indication of therapy, and duration of antibiotic therapy. Baseline serum creatinine (SCr), BUN, and creatinine clearance (CrCl) were recorded and documented. Serum creatinine, BUN, and urine output were collected throughout antibiotic therapy. Patients were screened for all co-morbidities. The patient's medication list was screened for any other medications that are associated with nephrotoxicity. If the patient was initiated on potentially nephrotoxic medications inpatient, the duration of therapy was recorded. Information for vancomycin and

piperacillin/tazobactam includes dose and dosing interval. Trough levels and changes in dose for vancomycin were recorded. Data was analyzed to assess the incidence of AKI and to determine if a relationship exists between dose of each medication and incidence of AKI.

Results: 25 patients from January 2014 to September 2016 met criteria. Of the 25 patients, 5 developed AKI (20%). Of the patients who were greater than 2 months of age and received vancomycin every 6 hours, 18.2% (2/11) developed AKI. Of the patients who were greater than 2 months of age who received vancomycin every 8 hours, 9.1% (1/11) developed AKI. 2 patients aged greater than 2 months who received vancomycin every 12 hours developed AKI (2/2, 100%). Four of the 25 patients did not have vancomycin troughs drawn. Four patients had trough levels above 20 mg/dL and three developed AKI (75%). Patients greater than 9 months and received piperacillin/tazobactam every 6 hours, 36.4% (4/11) developed AKI. Patients greater than 9 months and received piperacillin/tazobactam every 8 hours, 0 of the 11 patients developed AKI. The potentially nephrotoxic medications that were used in patients that developed AKI included: ceftazidime, ceftriaxone, ciprofloxacin, gentamicin, ibuprofen, pantoprazole, ranitidine, rifampin, and tobramycin. The average duration of therapy was 6 days. Of the 18 patients who received 6 or less days of therapy, 3 developed AKI (16.6%). Of the 8 patients who received greater than 6 days of therapy, 3 developed AKI (37.5%).

Conclusion: There was a correlation between patients receiving concomitant vancomycin and piperacillin/tazobactam therapy and AKI (20%). Patients who received vancomycin or piperacillin/tazobactam every 6 hours, had a vancomycin trough level greater than 20 mg/dL, received a potentially nephrotoxic drug (ceftazidime, ceftriaxone, ciprofloxacin, gentamicin, ibuprofen, pantoprazole, ranitidine, rifampin, and tobramycin), or received a higher duration of therapy had a higher percentage of AKI. If patients are to receive both medications simultaneously, vancomycin and piperacillin/tazobactam should be initiated at every 8 hours, goal vancomycin trough levels should be conservative, limit the use of potentially nephrotoxic drugs, and limit the length of therapy.

Submission Type: Evaluative Study

Session-Board Number: 3-093

Poster Title: Survival in critically ill adults with multidrug resistant Acinetobacter baumannii infections treated with ampicillin/sulbactam-containing versus non-ampicillin/sulbactam-containing regimens

Primary Author: Smit Patel, University of Georgia College of Pharmacy, Georgia; **Email:** spatel20@uga.edu

Additional Author (s):
Amy Taylor
William Hawkins
Carlos Franco-Paredes
Daniel Chastain

Purpose: Multidrug resistant (MDR) gram negative pathogens pose a serious threat in the healthcare setting. Of these, up to 74 percent of Acinetobacter baumannii infections in the intensive care unit (ICU) are MDR. The optimal antibacterial regimen for MDR A. baumannii is unknown. The efficacy of β-lactamase inhibitors is currently being evaluated, with sulbactam having the greatest intrinsic activity against A. baumannii. To our knowledge, no data is available evaluating ampicillin/sulbactam (AMP/SLB)-containing regimens for the treatment of MDR A. baumanii. The purpose of this study was to compare survival in critically ill patients receiving (AMP/SLB)-based therapy with those who are not.

Methods: The institutional review board approved this single-center retrospective observational cohort study evaluating survival outcomes in patients who received AMP/SLB-based therapy versus patients who did not. All adults 18 years of age or older admitted to the ICU with positive respiratory, blood, or wound cultures within 48 hours of their hospital stay for MDR A. baumannii from January 1, 2012 through July 31, 2016, were included. Patients were excluded if pregnant, had an anaphylactic reaction to penicillin, or a positive urine culture with A. baumannii. MDR A. baumannii was defined as being resistant to at least two classes of antibiotics on an automated susceptibility report. Data collected included antibiotic use in the past three months, hospitalizations or surgeries within the past 12 months, long-term care facility stay within the past 12 months, and the duration of mechanical ventilation, if applicable. The data that was collected was analyzed using descriptive statistics.

Results: Eighteen patients were included in this study. Sixty percent were male with a mean age of 56.8 plus or minus 20.1 years, who were on either AMP/SLB based therapy (22 percent) or a non-AMP/SLB based therapy (78 percent). The mortality rate between the arms was not clinically different. The AMP/SLB arm had two out of four patients die (50 percent) and the non-AMP/SLB arm had six of fourteen patients die (43 percent). Analysis showed that patients with bloodstream infections had a higher mortality than patients with respiratory tract infections. Of patients with bloodstream infections, 63 percent (5/8) died while 33 percent (3/9) of patients with respiratory tract infections died. Patients treated with AMP/SLB based regimens had a decreased length of ICU stay compared to those treated with a non-AMP/SLB based regimen, 7 days to 15 days, respectively.

Conclusion: Based on our data no difference in mortality rate was observed in patients treated with an AMP/SLB based regimen compared to a non-AMP/SLB based regimen. However, length of stay is shorter amongst patients in the AMP/SLB arm. AMP/SLB may represent a better option for patients infected with A. baumanii.

Poster Title: Evaluation of therapeutic duplication for inpatients prescribed as needed antihypertensive medications at an academic medical center

Primary Author: Sarah Clements, University of Georgia College of Pharmacy, Georgia; **Email:** sjclem@uga.edu

Additional Author (s):
Stephanie Lively

Purpose: In efforts to provide highest-quality patient care, healthcare professionals must collaboratively ensure that medication orders are clear and accurate. Pharmacists, in particular, play a critical role in reviewing the appropriateness of all medication orders. Therapeutic duplication is a component of this review and is defined by this institution as the presence or use of multiple medications for the same indication without clarification or a specified sequence of administration. The primary objective of this study was to assess the occurrence of therapeutic duplication for antihypertensive medication orders with as needed frequency.

Methods: A retrospective chart review was conducted for a random sample of patients admitted to this academic medical center between January 1, 2016 and June 30, 2016 who were prescribed two or more as needed antihypertensive medications during a single admission. These medications included clonidine, hydralazine and labetalol. Data collection included patient location and medical service, name and dosage of the medication ordered, start and stop time of each medication order, route of administration and presence of order comments indicating parameters and/or sequence for use. Descriptive statistics were used to analyze the data. This project was part of the institution's Medication Use Evaluation and Improvement Program, which has been reviewed by the Institutional Review Board and determined not to be human subject research.

Results: 155 patient encounters associated with 329 medication orders were evaluated for therapeutic duplication. Two active orders for as needed antihypertensive medications were noted in 91 percent of these patient encounters, three active orders were noted in 5.8 percent of these patient encounters and four active orders were noted in 3.2 percent of these patient encounters. Review of the 329 medication orders revealed that 94.5 percent of orders included

a comment defining blood pressure parameters for use and/or clarifying the sequence for administration. 5.5 percent of orders did not contain a comment or clarification. Of the 311 orders with comments, 82 percent of orders included the antihypertensive parameters for use only, while 18 percent of orders defined both blood pressure parameters for use and the sequence for administration. Overall, 83 percent of orders did not contain a comment or did not define both the parameters and sequence and, therefore, were considered duplicate therapy. Therapeutic duplication was most commonly noted in patients admitted to intensive care units, and intravenous hydralazine and labetalol were the most common agents prescribed.

Conclusion: Because therapeutic duplication may result in misinterpretation and increase the risk of adverse drug events, it is the responsibility of the prescriber to include pertinent information at the time of order entry and the obligation of pharmacists to seek clarification. The results of this medication use evaluation indicate a need for policy and protocol development related to therapeutic duplication, computerized prescriber order entry modification and staff education.

Poster Title: Retrospective evaluation of prescribing patterns of analgesia and sedative medications in critically ill adults during targeted temperature management after non-traumatic cardiac arrest

Primary Author: Jake Davis, University of Georgia College of Pharmacy, Georgia; **Email:** jdavis46@uga.edu

Additional Author (s):
Natalie Chong
Anthony Hawkins

Purpose: Targeted temperature management (TTM) is used to help prevent neurological damage in patients who have suffered from non-traumatic cardiac arrest. Patients must be in a comatose state to be eligible for this treatment modality. It is uncertain of the role of analgesic and sedative medications due to the neurologic deficit at the time of cooling. The purpose of this study is to examine the prescribing patterns of analgesic and sedative medications in patients receiving TTM.

Methods: This is a single-center retrospective observational cohort study conducted at a 450-bed community teaching hospital. It was approved by the institutional review board with waived consent. All patients at least 18 years old admitted to the medical, surgical, or cardiac intensive care units (ICU) and received TTM between October 1, 2015 and July 31, 2016 were eligible for inclusion. Patients were excluded if they received TTM not due to non-traumatic cardiac arrest or if they did not receive any sedative agent. Demographic data and baseline laboratory values were manually extracted from the electronic medical record. The type and quantity of analgesic and sedative medications was reviewed in the medication administration record (MAR). The primary outcome is to describe the prescribing patterns of analgesia and sedative medications in critically ill adults during TTM.

Results: Nineteen patients were eligible for inclusion, but 5 were excluded from our study. Two patients underwent TTM for other reasons besides non-traumatic cardiac arrest, and three out of the 17 patients did not receive a sedative during TTM. Of the 14 patients that were included in this study, 6 (43 percent) received analgesia during the TTM via continuous fentanyl infusion.

Also, 5 (36-percent) of the patients received analgesia for the entire 24-hour protocol. The 24-hour fentanyl exposure ranged from 708mcg to 5787mcg.For the choice of sedative, 2 (14-percent) of the patients received midazolam, and 12 (86-percent) received propofol. Thirteen (93-percent) patients received the sedative agent for the entire 24-hour protocol. The doses for patients receiving midazolam ranged from 93.7 to 198.2mg. The doses for patients receiving propofol ranged from 463mg to 5309mg. A total of 9 (64-percent) patients died while in the hospital.

Conclusion: There is variability in prescribing of both analgesic and sedative medications in adult patients receiving TTM. The need for and selection of these agents may impact patient outcomes and/or complications associated with TTM. Further studies are warranted to assess safety and efficacy of these agents.

Poster Title: Pharmacy interns' perceptions of Spanish-speaking patients

Primary Author: David Kim, University of Georgia College of Pharmacy, Georgia; **Email:** david364@uga.edu

Additional Author (s):
Barrett Darley

Purpose: The Hispanic population of the United States is the nation's largest ethnic minority. The U.S. Department of Health and Human Services has published guidelines to promote equal access to health care for diverse populations. According to these standards, culture and language have a significant impact on how patients access and respond to health care services. This project conducted at the University of Georgia College of Pharmacy (UGA COP) was designed to provide insight into pharmacy interns' perceptions of Spanish-speaking patients.

Methods: The institutional review board at the University of Georgia approved this survey-based study. During a 4-week data collection period in August 2016, a questionnaire was emailed to all pharmacy interns at the UGA COP through college listservs, with three reminder emails sent requesting participation. The survey was divided into 4 sections: demographics of pharmacy students, language assistance services available at pharmacy interns' pharmacies, attitudes of interns towards counseling Spanish-speaking patients, and cultural sensitivity of pharmacy interns. Descriptive statistics were utilized to analyze study results.

Results: Of 567 interns emailed, 73 completed surveys were returned. Of the respondents, 85.7 percent considered language services effective if they had the service available in their pharmacy. The majority, 62.5 percent, also agreed (somewhat agreed to strongly agreed) that non-Spanish speaking pharmacy interns have a responsibility to counsel those who only speak Spanish. In addition, 80.3 percent agreed (somewhat agreed to strongly agreed) that pharmacy interns have a responsibility to interact and learn the culture/language of their patients. However, 64.3 percent disagreed (somewhat or strongly) or were neutral when asked whether the college's instructional strategies sufficiently prepared students to interact with Spanish-speaking patients.

Conclusion: Study results indicated the majority of pharmacy interns at the UGA COP perceive cultural sensitivity toward Spanish-speaking patients as an important component of successful pharmacy practice. In this survey, most pharmacy interns agreed they have a responsibility to learn about different patient cultures and to counsel Spanish-speaking patients. Overall, they felt language assistance services were effective; however, they did not believe sufficient education in cultural sensitivity was provided during pharmacy school. Efforts to encourage cultural sensitivity and education should continue to be made to ensure equal access to pharmacy services for Spanish-speaking patients.

Poster Title: Utilization of dalbavancin through a pharmacist-directed pilot project aiming to reduce length of stay at a community hospital.

Primary Author: Vanessa Jenkins, University of Georgia College of Pharmacy, Georgia; **Email:** vjenkins@uga.edu

Additional Author (s):
Bruce Jones
Roby Hersey

Purpose: With the increasing incidence of serious gram-positive bacterial infections and decreased susceptibility, patients are requiring extended hospital stays due to need for parenteral administration of antimicrobials. Dalbavancin is an intravenous (IV) lipoglycopeptide antibiotic that has activity against gram-positive pathogens, including methicillin-resistant Staphylococcus aureus, in acute bacterial skin and skin structure infections (ABSSSI). With an extended half-life of 14.4 days, one administration in an outpatient infusion center provides a full treatment course of antimicrobial activity. Through a pharmacist-directed pilot project at our institution, dalbavancin is recommended in appropriate patients to effectively treat the infection and reduce hospital length of stay (LOS).

Methods: This study is a retrospective chart review to assess the use of dalbavancin between March and September of 2016 at a community hospital. The antimicrobial stewardship program pharmacist provided a list of adult patients who were admitted to the hospital and completed dalbavancin therapy at the outpatient infusion center. All patients included in the study received dalbavancin 1500mg once in an outpatient infusion center affiliated with the hospital. Patients were excluded if they were not previously admitted to the hospital before administration of dalbavancin. Data was collected from the computerized patient record system and included: age, gender, weight, race, IV drug use, LOS, type of infection, outpatient antibiotics, systemic signs of infection upon admission, incision and drainage, microbiology, inpatient antibiotics, and 30-day readmission. The primary outcome of the study is LOS. LOS will be measured from the time of admission for patients admitted for treatment of ABSSSI until discharge. Secondary outcomes include severity of illness upon admission and 30-day readmission, both infectious and non-infectious. Severity of illness is based on presence of

systemic signs of infection upon admission including temperature greater than or equal to 38°C, white blood cells (WBC) greater than 12,000 cells/mm3, and immature WBC forms greater than or equal to 10%.

Results: Out of 28 total patients screened, 1 was excluded for not being admitted to the hospital prior to dalbavancin administration. Infections treated include diabetic foot infection, cellulitis, abscess, osteomyelitis, bacteremia, and infected venous access port. 15 of the 27 patients previously failed outpatient antimicrobials prior to admission to the hospital. Three of the patients were IV drug users that were not appropriate candidates for scheduled outpatient IV antibiotics or central line administration. Dalbavancin, due to the one-time administration, could be given to this patient population safely. All of the patients that were assessed in this study received vancomycin alone or in combination throughout their hospital stay. LOS in the hospital ranged from 2 to 40 days with an average of 6.4 days. The average LOS was 5.1 days for cellulitis and/or abscess and 8.0 days for bacteremia. Based on CDC national average hospital LOS from 2010, LOS for cellulitis and/or abscess is 4.4 days, while the bacteremia LOS is 8.8 days. Systemic signs of infection were present in 14 patients. Of the 27 patients reviewed, there was a one patient with an infection-related readmission within 30 days.

Conclusion: This retrospective study demonstrated dalbavancin is effective for treatment in a variety of infections. Limitations of the study include small sample size that may reduce generalizability. This study suggests gram-positive bacterial infections can be treated with dalbavancin in an outpatient infusion center with low risk of 30-day readmission. While the LOS is longer than the national average, the baseline of this clinical site is unknown and may have been reduced with dalbavancin utilization. A screening protocol would be beneficial to identify appropriate patients for dalbavancin early in their hospitalization to make a larger impact on LOS reduction.

Submission Type: Descriptive Report

Session-Board Number: 3-098

Poster Title: The Impact of Pharmacy student involvement on diabetes care in the hospital setting

Primary Author: Titus Gates, University of Georgia College of Pharmacy, Georgia; **Email:** titusg@uga.edu

Additional Author (s):
John Stevick
Robin Southwood

Purpose: Performance measures for pharmacy students while on rotations are key to both the school and the institutions in which they work. Together both gain a sense of how students utilize their knowledge while patients benefit from clinical, yet supervised care. In particular, proper inpatient medication therapy and education to strengthen patient compliance upon discharge are essential components of hospital patient care. This poster is meant to display some of the clinical impact that advanced pharmacy practice students have in regards to diabetes care and education in a Joint Commission Disease State Specialty accredited high-ranking hospital.

Methods: IRB approval was obtained. The hospital diabetes care team documents activities regarding diabetes education, management, and follow-up were documented using a Microsoft Access system located on a secure network drive. Data for a xxxx month time period was exported into an excel spreadsheet. Patient data was previously de-identified to follow HIPAA protocol as well keep anonymity of which students made which type of interventions. The student data was extracted from and compared to a larger data base of the diabetes care team interventions. The data presented describes contributions by on their fourth year doctor of pharmacy students in recommending changes in initiation and management of drug therapy, monitoring/assessment of diabetes control using evidence-based guidelines and hospital formularies. Students also counseled and educated patients with diabetes mellitus including pathophysiology, risk factors, home monitoring of blood glucose, management of hyper- and hypoglycemia, lifestyle modifications, and even basic nutrition with certified diabetes educators. Students also counseled patients on insulin use as well as oral medication therapy and identified barriers to accessing medication and supplies.

Results: 2395 patient interactions were documented by students in which various interventions were made. Of those interactions recommendations regarding changes in therapy as well as educational services were documented. A majority of the recommendations were accepted and enacted by physicians, nurses and patients. Preceptors also approved a majority of the student recommendations and co-signed on documentation. The bulk of student interventions involved (patient follow-ups with their primary care physicians, diabetes education and monitoring, assessing compliance, and clarifying home medication regimens. Other interventions included oral and insulin therapy along with associated education, medication clarification, and hypoglycemia evaluation and education.

Conclusion: Pharmacy school students can have a significant impact on the healthcare team in a hospital setting and future endeavors regarding disease education, management, and treatment can be implemented using fourth year pharmacy students to better improve patient care (and reduce errors?) for hospitals. Engaging students in this role of diabetes management also showed the benefits of coordination amongst multiple healthcare disciplines including but not limited to physicians, nurses, medical students and residents, and social work. This can open the door for wider involvement in patient care for pharmacists in other chronic health conditions which can reduce workload for healthcare providers.

Poster Title: Evaluation of a nurse-driven electrolyte replacement protocol in the adult intensive care unit at an academic medical center

Primary Author: Belinda Li, University of Georgia College of Pharmacy, Georgia; **Email:** bel26@uga.edu

Additional Author (s):
Asha Patel
Jacquelyn Bryant
Ah Hyun Jun

Purpose: Electrolyte deficiencies in critically ill patients can have fatal consequences, including respiratory and cardiovascular decline. Historically, ICU electrolyte replacement at Augusta University Medical Center was physician-driven; however, electrolyte management by nurses may allow physicians to focus on higher priority medical issues. A nurse-driven, ICU electrolyte replacement protocol was implemented to provide nurses with the autonomy to order laboratory values and replace electrolytes in critically ill, adult patients. The goal associated with protocol implementation was to more appropriately manage electrolytes through standardized and timely replacement. The purpose of this study is to evaluate the efficacy of a nurse-driven, electrolyte replacement protocol.

Methods: The institutional review board approved this retrospective chart review of electrolyte replacement for potassium, magnesium, phosphorus, and calcium in adult patients admitted to the medical intensive care unit at AUMC. Patients for the pre-protocol group were included in the analysis if they met the current electrolyte protocol's usage requirements (serum creatinine less than 2 mg/dL, urinary output greater than 30 mL/hr, weight greater than 50 kg, not requiring renal replacement therapy, not admitted for a diagnosis of diabetic ketoacidosis, and not undergoing targeted temperature management) and demonstrated low electrolyte concentrations constituting physician-driven electrolyte replacement from January to March 2015. Patients were included in the post-protocol analysis if they were placed on the nurse-driven, electrolyte replacement protocol from April to August 2016. Time to administration, frequency of monitoring after replacement, and ability to adequately increase serum electrolyte levels to normal values were assessed in both pre-protocol and post-protocol

patients. Nursing adherence to the protocol was based upon time to electrolyte order placement and repletion, appropriate dosage form and amount replaced, and appropriate reassessment after replacement (within four hours after completion of electrolyte administration).

Results: Twelve patients in each arm were included in the retrospective chart review and displayed similarities in age, gender, race, weight, and renal function. On average, 36 percent of electrolytes were adequately replaced to therapeutic levels in pre-protocol patients compared to 31 percent in post-protocol patients. The average time to placement of an electrolyte order following an initial low electrolyte level was 173 minutes post-protocol compared to 159 minutes pre-protocol. The time from an initial low electrolyte laboratory value to administration of electrolyte repletion was shorter post-protocol by 30 percent (105 minutes) for potassium replacement, 31.5 percent (97 minutes) for magnesium replacement, and 7 percent (13 minutes) for calcium replacement compared to pre-protocol, however administration of phosphorous replacement was longer in post-protocol patients by 32.5 percent (132 minutes). Appropriate monitoring, which was defined as obtaining another laboratory value within four hours from the completion of electrolyte administration, occurred more frequently in the post-protocol group (35 percent) than in the pre-protocol group (13 percent). In the post-protocol arm, nurses appropriately followed the protocol in 77 percent of patients, with regards to the need for replacement, amount replaced, and dosage form used.

Conclusion: The results of this study demonstrated an improvement with the use of the electrolyte replacement protocol in regards to time to administration for all electrolytes, except phosphorus. Time to placement of electrolyte orders was longer post-protocol and the frequency of appropriate monitoring was still low, indicating a need for re-education of the protocol requirements. The results of this study also illustrate a higher percentage of adequate electrolyte repletion to therapeutic levels prior to the implementation of a nurse-driven protocol, suggesting the need for a more aggressive protocol.

Session-Board Number: 3-100

Poster Title: Retrospective evaluation comparing balanced crystalloid with 0.9% sodium chloride when used as maintenance therapy in critically ill adults

Primary Author: Laura Hill Bannister, University of Georgia College of Pharmacy, Georgia; **Email:** lhbann@uga.edu

Additional Author (s):
Anthony Hawkins

Purpose: Hemodynamic management is a vital component in managing critically ill patients. Fluid resuscitation is used to correct baseline volume deficits. Balanced crystalloids (BC) and 0.9-percent sodium chloride (NS) have been compared to determine the optimal fluid for resuscitation. Complications associated with NS include hyperchloremia and acute kidney injury (AKI), whereas BC may cause hyperkalemia. Following resuscitation, maintenance intravenous fluids (mIVF) are commonly administered to sustain intravascular volume. The optimal fluid choice for maintenance infusion has not been evaluated. The purpose of this study is to compare outcomes of critically ill adults that received NS-based mIVF with those that received BC.

Methods: This is a single-center retrospective cohort study conducted at a large community teaching hospital and approved by the institutional review board. All patients over 17 years old admitted to the medical intensive care unit (ICU) between October 1, 2015 and July 30, 2016 were eligible for inclusion. Patients were excluded if transferred from another hospital, ICU stay less than 72 hours, or had past medical history significant for end stage renal disease. Patients were divided into two groups based on type of mIVF received: NS and BC. We defined BC as lactated ringers and PlasmaLyte. Demographic data, laboratory results, type and quantity of resuscitation fluid, and type and duration of mIVF were collected. Resuscitation fluid was defined as any fluid received in the initial 24 hours or infused at a rate greater than 250mL/hr. Maintenance fluid was defined as fluid infused at a rate less than or equal to 250mL/hr. The primary outcome of the study was the incidence of AKI, defined as an increase in serum creatinine by at least 0.3mg/dL within 48 hours. Secondary outcomes included the incidence of hyperchloremia, defined as serum chloride grater than 110mEq/L, and hyperkalemia, defined as

serum potassium greater than 6.5mEq/L, need for dialysis, hospital length of stay, and in-hospital mortality.

Results: Eighteen patients were included in the analysis (BC including 7; NS including 11). Within the BC group, six patients received lactated ringers and one patient received PlasmaLyte. Patients were similar at baseline, with a Sequential Organ Failure Assessment score of 3.5 in the BC group and 4.2 in the NS group. Past medical history was comparable except diabetes, with 0 patients in the BC group and 36-percent in the NS group. The incidence of AKI was similar between BC and NS, 57-percent and 55-percent respectively. A greater number of patients required dialysis in the NS group (27-percent versus 0-percent). Hyperkalemia was more frequent in the NS group (18-percent) compared with BC (0-percent). There was no difference in the incidence of hyperchloremia between BC and NS, 57-percent versus 55-percent, respectively. Length of stay was longer in the BC group with an average ICU length of stay of 13.43 days versus 7.91 in the NS group. These were also the results when looking at hospital length of stay. Conversely, administration of NS led to a higher rate of in-hospital mortality (73-percent versus 57-percent).

Conclusion: The choice of fluid when used as maintenance therapy did not impact the incidence of AKI. Patients treated with NS had a higher rate of hyperkalemia and in-hospital mortality when compared to BC. Use of BC was associated with a longer ICU/hospital length of stay. Practitioners should take this into consideration, as well as patient specific factors, when deciding which mIVF to prescribe in critically ill adults.

Poster Title: Resistance of Escherichia coli urinary isolates in emergency department-treated patients with healthcare-associated risk factors.

Primary Author: Rachel Wilkes, University of Georgia College of Pharmacy, Georgia; **Email:** rachwilk@uga.edu

Additional Author (s):
Devin Lavender
Angelina Cho
William Moore
Virginia Fleming

Purpose: Urinary tract infections are a common condition treated in the Emergency Department (ED). While most cases are community-acquired infections, a portion of patients presenting from the community may carry/possess risk factors for healthcare-associated infections that increase chances of isolating a drug resistant pathogen. Escherichia coli (E.coli) is the most common pathogen for all UTI types, but there may be a greater chance of drug resistant E.coli in healthcare-associated (HA-UTI) patients that may not be accurately represented by the cumulative hospital antibiogram. Our study evaluated the rates of E.coli resistance to commonly prescribed oral antibiotics in ED-treated patients with HA-UTI.

Methods: A retrospective medical record review of culture-positive patients treated in the ED of a 200-bed community hospital from January 1, 2015 to June 14, 2015 was performed. Patients with urinary isolates of greater than 100,000 cfu/ml and at least one healthcare-associated risk factor who were treated for UTI in the ED were included. The following healthcare-associated risk factors were used: residence in long term care facility or nursing home, indwelling urinary catheter, immunosuppressive therapy or disease, hospital admission for 2 or more days in the previous 90 days, urologic procedure in the previous 90 days, and chronic dialysis in the previous 30 days. Other potential risk factors for drug resistance such as recent antibiotic therapy and history of previous or recurrent UTI were also collected. Patients who required admission, were pregnant, less than 18 years of age, or who had asymptomatic bacteriuria, no intention to treat by physician, or cultures with less than 100,000 cfu/ml were excluded. For patients who returned to the ED within 7 days of the initial visit with the same

pathogen, only the first encounter was included. Causative bacteria, drug susceptibilities, and antimicrobial therapies were recorded for evaluation. E.coli resistance rates in the subgroup of ED patients with HA-UTIs were compared to the cumulative hospital antibiogram and also to data from a previous study performed at the same institution in 2011.

Results: Of the 385 patients screened, 46 patients were included. The most common risk factors resulting in healthcare-associated designation were indwelling catheter (45.6 percent), long-term care facility/nursing home residence (39.1 percent), and hospital admission for more than 2 days in the last 90 days (39.1 percent). Almost half of the HA-patients received antibiotic therapy in the last three months (47.8 percent) and/or had at least one previous hospitalization in the last 6 months (28.3 percent). The most common causative pathogens included: E.coli, Klebsiella species, and Proteus mirabilis. Nine patients isolated two separate pathogens. Frequently prescribed empiric antibiotic therapies were: cephalexin (32.6 percent), nitrofurantoin (30.4 percent), levofloxacin (23.9 percent), ciprofloxacin (13 percent), and sulfamethoxazole/trimethoprim (10.9 percent). E.coli resistance rates were 48 percent for levofloxacin and ciprofloxacin, 40 percent for SMX/TMP, 20 percent for cephalexin, and 16 percent for nitrofurantoin. Compared to E.coli resistance rates to levofloxacin reported on the hospital antibiogram, HA-UTI patients had much higher fluoroquinolone resistance (27 vs 48 percent, respectively) and also were higher than those seen in a similar 2011 study of HA-UTI patients at the same institution (38.5 percent in 2011 vs 48 percent). Empiric therapy was effective for the causative pathogen in 67.4 percent of cases.

Conclusion: ED-treated patients with healthcare-associated UTIs were found to have higher rates of resistance to levofloxacin than those reported on the cumulative hospital antibiogram and when compared to a previous study of HA-UTI patients in 2011. Interestingly, fluoroquinolones were not the most commonly prescribed oral therapies by our ED physicians in this patient population. This is a prescribing pattern that changed from the institution's previous 2011 study. Identification of HA risk factors in ED-treated patients is important when choosing empiric antibiotic therapy and further study is needed to determine the best antibiotic therapy options for ED-treated patients with HA-UTI.

Poster Title: Evaluation of antithrombin III utilization and dosing strategy in pediatric population at an academic medical center

Primary Author: Ruchita Amin, University of Georgia College of Pharmacy, Georgia; **Email:** rpamin92@uga.edu

Additional Author (s):
Kelley Norris

Purpose: Thrombate III is commonly used to replace antithrombin (AT) in patients with a hereditary deficiency. Thrombate III is also administrated to patients with iatrogenic deficiency to decrease the risk of coagulation by increasing the level of antithrombin. Even though antithrombin III replacement using Thrombate III in pediatric patients has not been widely studied, it is commonly used off-label in various pediatric clinical settings. The purpose of this study is to evaluate the use and dosing strategy of Thrombate III in the pediatric population at an academic medical center.

Methods: A retrospective chart review was performed on a sample of 26 patients who received at least one dose of Thrombate III (T3) while in the Children's Hospital of Georgia from September 2015 to September 2016. Data collection included patient demographics (age, gender, weight, and location), indication for T3 use, dose of T3, concurrent heparin use and dose, lab values while receiving T3 (AT levels, aPTT, HepXa, ACT, and platelet counts), duration of therapy to achieve AT level within target range, and presentation of adverse events due to T3 and/or heparin administration. This project is part of the health system medication use evaluation and improvement program, which is considered "not human subjects research" by the institutional review board.

Results: Of the 26 patients reviewed, 16 patients (61.5 percent) were in neonatal intensive care unit (NICU) and 10 patients (38.5 percent) were in pediatric intensive care unit (PICU). All NICU patients received T3 for extracorporeal membrane oxygenation (ECMO), 14 patients (87.5 percent) received a standard dose of 125-units/kilogram. Average time to AT trough above 80 percent: 21.6 hours on standard dose, 15.8 hours on lower doses (108 and 114-units/kilogram). All patients received a continuous heparin infusion. Ten patients (62.5 percent) developed clots,

5 (50 percent) required an ECMO circuit change. ECMO was the most common indication for AT administration in PICU (7 patients; 70 percent). Four patients received 125-units/kilogram standard dose, target trough in 21 hours. Three patients received doses ranging 31 to 104.2-units/kilogram, target tough in 56 hours. One PICU patient (10 percent) received T3 for continuous veno-venous hemofiltration at single dose of 53.1-units/kilogram; time to target trough undeterminable. Two PICU patients (20 percent) received T3 for low levels. One patient received 125-units/kilogram, target trough in 4 hours. The other patient received 50-units/kilogram, target trough in 56 hours. All patients received continuous heparin infusion. Six patients (60 percent) developed clots; 1 (16.7 percent) required an ECMO circuit change.

Conclusion: Results suggest the T3 dose in the NICU needs further evaluation in achieving target trough in a timely manner, while the standard dose of 125-units/kilogram may be sufficient in the PICU.

Poster Title: Limitations to leading: Student pharmacists' perceptions of leadership opportunities during the third professional year in a 2+2 program

Primary Author: Alyssa Elrod, University of Georgia College of Pharmacy, Georgia; **Email:** aelrod@uga.edu

Additional Author (s):
Ashley Hannings
Barrett Darley
Linda Logan

Purpose: The Accreditation Council for Pharmaceutical Education (ACPE) Standards emphasize personal and professional development for student pharmacists. Colleges of pharmacy are becoming more invested in assessing student leadership potential and involvement. In addition, many colleges of pharmacy now have satellite campuses, adding additional advantages and challenges for student leadership development. The purpose of this study was to identify limiting factors for student pharmacists in the participation of leadership opportunities during the third professional (P3) year at a college of pharmacy with a 2+2 program.

Methods: This study utilized a research protocol and instrument previously approved by the University of Georgia (UGA) Institutional Review Board. This project was a supplement to the original study and was determined to be exempt from full review. Data collection occurred during a one-week period in September 2016. The Qualtrics survey was initially emailed to the UGA College of Pharmacy Class of 2017 (n=144) via the class listserv with two reminders requesting participation. Leadership opportunities were defined at the beginning of the survey. Students were asked to reflect back to leadership opportunities available during their P3 year.

Results: A total of 21 students completed the survey. Only two out of four campuses were represented with one being the main campus. The majority of respondents (86%) planned to pursue leadership opportunities during their P3 year. Respondents were asked to identify limitations to participating in leadership opportunities, selecting all limitations that applied. The limitations identified included school responsibilities (81%), work responsibilities (62%), perceptions of their own leadership abilities (57%), hobbies (33%), relationships (29%), campus

location (24%), and family responsibilities (14%). Two respondents did not identify limitations to participation (9%). When asked to rank the identified limitations from most to least limiting, 38% of respondents selected school responsibilities, 15% selected hobbies, and 15% selected campus location as the most limiting factor.

Conclusion: This study identified multiple limitations to student participation in leadership opportunities during the P3 year. While some factors were personal, other barriers identified may be minimized by college initiatives. For example, for the students who identified perceptions of their own leadership abilities as a limitation, the College could offer leadership development programming to increase students' confidence in their abilities. Campus location was also noted as a limitation. The College continues to examine equality of personal and professional development opportunities among all campuses. However, input is needed from all four campuses to adequately address student needs.

Poster Title: Does dysregulated ferritin have sustained adverse effects on morbidity and mortality in adults infected with human immunodeficiency virus (HIV) taking highly active antiretroviral therapy (HAART)?

Primary Author: Raybun Spelts, University of Georgia College of Pharmacy, Georgia; **Email:** raybun2012@gmail.com

Additional Author (s):
Grace Vahey
David Guwatudde
Wafaie Fawzi
Amara Ezeamama

Purpose: Identifying modifiable risk factors to better manage HIV as a chronic condition has become critical. The purpose of this study was to assess associations between normal versus dysregulated baseline ferritin levels and changes in five clinical outcomes (immunological status, quality of life [QOL], body mass index [BMI], hospitalization, and mortality) over 18 months in HIV-infected adults on HAART. Iron dysregulation can be corrected through various methods, including iron supplementation, reduction, or chelation therapies. If iron dysregulation adversely affects health outcomes in this population, pharmacists may be able to monitor ferritin levels and correct dysregulated ferritin.

Methods: This 18 month longitudinal study, conducted in Uganda, was approved by the institutional review boards of Harvard School of Public Health and Makerere University School of Public Health. Informed consent was obtained from all participants. Clinical, socio-demographic, and behavioral characteristics were taken from 398 HIV-infected adults on HAART. Participants were divided into three groups by serum ferritin level measured at enrollment. Low ferritin was defined as less than 30 micrograms per liter. High ferritin was defined as greater than 150 micrograms per liter for women and 200 micrograms per liter for men. Those not meeting the definition for low ferritin or high ferritin were considered to have normal ferritin levels. Immunologic status (measured using CD4 cell counts), QOL, and BMI were measured every six months. Time to first hospitalization and death events were calculated as months from enrollment. For non-hospitalized participants, follow-up was calculated as

months from enrollment to last study visit. Multivariable random effects linear mixed regression models quantified the associations between ferritin status and changes in CD4 cell count, BMI, and QOL. Risk differences and 95 percent confidence intervals in mean CD4 cell counts, BMI, and QOL by ferritin status at enrollment were calculated at baseline and every six months. Hazard ratios were calculated for dysregulated ferritin versus normal ferritin groups using Cox regression to reflect differences in time to hospitalization or death.

Results: The study population was 69.1 percent female and the mean age was 35.8 years. Fifty percent of the participants were HAART-naïve at enrollment. Of the 398 participants, ferritin was low, normal, and high in 17 percent, 42.5 percent, and 40.5 percent respectively. The three groups differed by sex (P less than 0.0001), mean age (P less than 0.0001), and mean BMI (P equals 0.0009). There was no difference in mean QOL score or CD4 cell count. Independent of baseline ferritin level, QOL, CD4 cell count, and BMI improved for all participants over 18 months (P less than 0.0001). Baseline ferritin levels predicted changes in QOL (P equals 0.0112) and weight gain (P equals 0.0432) but not CD4 cell count (P equals 0.7720). Both high ferritin levels (adjusted hazard ratio [AHR] equals 1.78; 95 percent confidence interval [CI]: 1.00 to 3.15) and low ferritin levels (AHR equals 1.98; 95 percent CI: 1.01 to 3.86) were associated with increased hospitalization or mortality compared to normal ferritin levels.

Conclusion: Dysregulated ferritin level, both elevated and low, at enrollment predicted greater risk of hospitalization or mortality and lower QOL over 18 months in HIV-infected adults. Weight gain over follow-up was also dependent on baseline ferritin level, but the clinical relevance of this association warrants further elucidation. Our results suggest that clinicians, including pharmacists, should routinely monitor ferritin in HIV-infected patients and correct dysregulated levels. These actions could be useful in avoiding adverse long-term health outcomes in this population.

Poster Title: Resistance of Escherichia coli urinary isolates in patients with community-acquired urinary tract infections treated in the emergency department of a community hospital

Primary Author: Devin Lavender, University of Georgia College of Pharmacy, Georgia; **Email:** dll2882@uga.edu

Additional Author (s):
Rachel Wilkes
William Moore
Angelina Cho
Virginia Fleming

Purpose: Urinary Tract Infections (UTIs) are commonly treated in the Emergency Department (ED) and are frequently caused by Escherichia coli (E.coli). Fluoroquinolones are often prescribed for outpatient UTI treatment, but E.coli resistance is increasing. Our hospital antibiogram reported high E.coli resistance to these agents but is cumulative of a diverse patient population. This study was performed to determine resistance of E.coli urinary isolates to commonly prescribed oral antibiotic therapies in ED-treated patients with community-acquired UTIs (CA-UTI). Additionally, we compared resistance rates of the CA-UTI population to those of a prior study performed in 2011 of ED-treated CA-UTI patients.

Methods: A retrospective medical record review of culture-positive patients treated for urinary tract infections in the emergency department of a 200-bed community hospital from January 1, 2015 to June 14, 2015 was performed. Adult patients with urinary isolates of >100,000 cfu/ml with documented intention to treat were included. Patients who were hospitalized, pregnant, under 18 years of age, with < 100,000 cfu/ml on urine culture, or who did not have documented intention to treat were excluded. For patients who returned to the ED within 7 days of the initial visit, only the first encounter was included. Patients with risk factors for healthcare-associated urinary infection were assessed in a separate review. Healthcare associated risk factors included residence in long term care facility or nursing home, presence of an indwelling urinary catheter, immunosuppressive disease or therapy, hospital admission for 2 or more days in the previous 90 days, urologic procedure in the previous 90 days, and chronic dialysis in the previous 30 days. Information regarding other potential risk factors for drug resistance such as

previous recent antibiotic treatment and history of prior or recurrent UTIs was also recorded. Resistance rates were compared to both the cumulative hospital antibiogram and to data from a 2011 study of E.coli resistance in ED-treated patients at the same institution. Causative bacteria, drug susceptibilities, and antimicrobial therapy were recorded for evaluation.

Results: Of the 385 patients screened, 277 were included in our evaluation. Of the 277 patients included, 83.4 percent (n=231) of included patients were classified as community-acquired UTI (CA-UTI) and 16.6 percent (n=46) of patients had at least one risk factor for a healthcare-associated pathogen. The most common causative pathogens were E.coli (76.1 percent) and Klebsiella species (12.5 percent). Nineteen patients grew multiple pathogens, representing 6.9 percent of the evaluated population. The most commonly prescribed antibiotics were nitrofurantoin (37.7 percent), cephalexin (36.4 percent), levofloxacin (4.8 percent), and sulfamethoxazole/trimethoprim (8.7 percent). For community-acquired patients, resistance of E.coli was 15.9 percent to levofloxacin, 26.1 percent to trimethoprim-sulfamethoxazole, 5.7 percent to nitrofurantoin, and 3.4 percent to cephalexin. Causative pathogens were susceptible to empiric therapy in 88.1 percent of cases. E.coli resistance rates to levofloxacin in the community-acquired ED UTI patients were lower than those reported on the cumulative hospital antibiogram (15.9 percent vs 27 percent, ED vs antibiogram respectively). From 2011 to 2015, resistance of E.coli to levofloxacin increased in community-acquired ED UTI patients (9.2 percent vs 15.9 percent). Also, a noticeable decrease in fluoroquinolone use and an increase in cephalexin and nitrofurantoin use was seen when compared to the 2011 data set results.

Conclusion: Fluoroquinolones remain potential options for ED-treated patients with CA-UTI based on the resistance rates reported in our study. Despite exceeding the 10 percent threshold in the 2011 guidelines, E.coli resistance was lower than reported on the hospital antibiogram and comparable to other oral therapy options--though resistance to levofloxacin has increased from 9.2 percent to 15.9 percent since 2011. Recently, the FDA has recommended that fluoroquinolone use be limited when other alternatives exist due to risk of side effects and potentially overly-broad spectrum. Because of this, further study on resistance rates for other oral antibiotics for ED-treated CA-UTI patients is needed.

Submission Category: Quality Assurance/ Medication Safety

Submission Type: Descriptive Report

Session-Board Number: 3-106

Poster Title: Bedside medication reconciliation at emergency department discharge

Primary Author: Tu Trinh Tran, University of Georgia College of Pharmacy, Georgia; **Email:** ttran14@uga.edu

Additional Author (s):
Susan Jackson

Purpose: Currently, medication lists are not being reviewed at bedside prior to the patient being discharged from the Emergency Department. As a result, patients leave the hospital with an inaccurate list of medications and higher risk for adverse drug events. The purpose of this study is to determine the efficacy of medication reconciliation process at a community hospital emergency department. The primary endpoint was to identify whether having physicians review the medications lists with patients at bedside will improve medication reconciliation accuracy. Secondary endpoints included number of discrepancies found, number of medication interventions, and total time physicians spent completing medication reconciliation.

Methods: This Institutional Review Board (IRB) approved study is part of Hospital National Patient Safety Goals and Joint Commission Standards. A retrospective chart review was conducted on random sample of adult patients admitted and discharged from WellStar Kennestone Hospital Emergency Department between March 1st and August 31st, 2016. Data collection included patient demographics characteristics, name of medications, dose, frequency, route of administration, number of medications discrepancies found by physicians, type of discrepancies, number of interventions resolved by physicians, and total time physicians spent completing medication reconciliation at bedside. In this study, pharmacy students audited physicians' compliance to complete medication reconciliation at bedside prior discharge. Pharmacy students used EPIC to look at patients' medication lists summary prior to and after ED physicians reconciled the list of medications with patients. Any medication discrepancies between two lists were used to identify medication reconciliation accuracy. Auditors highlighted any discrepancies found by physicians and if physicians responded with clarification. Descriptive statistics were later used to describe the results found from the study.

Results: Out of 25 discharged patients, 23 (92 percent) patients had one or more medication discrepancies identified by the ED physicians during the medication reconciliation process at bedside prior to discharge. The accuracy of the medication list prior to review by physicians was 66.8 percent; however, the accuracy of the medication lists after medication reconciliation completed by physicians was 92.4 percent. Physicians found a total of 60 medication history related errors and resolved 44 (73 percent) of medication errors before discharge. The average time physicians spent completing medication reconciliation at bedside was 4 minutes and 16 seconds.

Conclusion: Medication reconciliation is an important process during transition of care. Medication reconciliation at discharge has the potential to detect and improve medication histories and reduce risk of adverse drug events. This project has demonstrated the usefulness of having a comprehensive medication reconciliation program. By implementing the medication reconciliation process at bedside prior discharge, it gives physicians an opportunity to identify, discuss and resolve any potential medication discrepancies with the patient.

Submission Type: Evaluative Study

Session-Board Number: 3-107

Poster Title: Evaluation of the use of ceftazidime-avibactam at Augusta University Medical Center

Primary Author: Andrew Karas, University of Georgia College of Pharmacy, Georgia; **Email:** akaras@uga.edu

Additional Author (s):
Sonal Patel

Purpose: The purpose of this evaluation is to assess the use of ceftazidime-avibactam at Augusta University Medical Center. By looking at patients treated with this antibiotic we hope to see it is being used for the appropriate indications, organisms, and to determine if the use of this antibiotic resulted in treatment success. As this antimicrobial agent is a last line agent for highly resistant organisms this evaluation would like to determine if it is being used as such.

Methods: This project is part of the institution's Medication Use Evaluation (MUE) and Improvement Program, which has been reviewed by the IRB and determined not to be human subject research. A retrospective chart review was performed on all patients who received ceftazidime-avibactam from January 1, 2015 to August 8, 2016 at Augusta University Medical Center. Collected data includes type of infection, indication, cultures if present, if infectious organisms are carbapenemase-resistant enterobacteriaceae (CRE) or multi-drug resistant (MDR) Pseudomonas aeruginosa are present, clinical improvement, readmission within 30 days, recurrence of infection, and treatment duration. 21 data points from 16 patients were analyzed for the above variables. Patient's protected health information was kept on a secure shared drive and each were given a random identification number on the data collection form.

Results: Out of the 16 total patients who received ceftazidime-avibactam 21 courses of the antibiotic were discovered and analyzed. For type of infection there were 10 incidences of pneumonia or cystic fibrosis (CF) exacerbation, 4 of intraabdominal infection, 1 urinary tract infection, and 2 miscellaneous infections which were febrile neutropenia and bacterial meningitis. It was also discovered that 5 courses were used as empiric therapy for patient who either had suspected CRE, MDR organisms, or a history of such infections. From culture data 42.9% of cultures were positive for CRE and 32.3% were positive for MDR Pseudomonas.

Clinical improvement was defined as if the patients improved enough post antimicrobial course to be discharged which was seen in 71.4% of the patients treated. Average treatment duration was 11 days. Two patients had readmission within 30 days or recurrence of infection, with the most frequent reason being CF exacerbation.

Conclusion: The data analysis determined that ceftazidime-avibactam is being used appropriately at Augusta University Medical Center. All infections with cultures were for organisms that this antibiotic would be the drug of choice for, and the empiric courses were appropriate based on patients' medical history, contraindications, or treatment failures of other agents. Due to the complicated nature of the patients treated ~30% of them passed away before completing a full course. After evaluating the use of this medication it is clear that it is being used appropriately as a last line therapy for difficult to treat organisms and not for everyday infections.

Submission Category: Critical Care

Session-Board Number: 3-108

Poster Title: Potential risk factors for dual antiplatelet-associated gastrointestinal bleeding following placement of a pipeline embolization device in patients with cerebral aneurysms

Primary Author: Charlotte Dunderdale, University of Georgia College of Pharmacy, Georgia; **Email:** cdunder@uga.edu

Additional Author (s):
Bill Asbury
Frank Tong
Susana Skukalek

Purpose: The pipline embolization device (PED) offers an alternative to patients with difficult to treat cerebral aneurysms who cannot undergo or have failed traditional endovascular treatments. Due to the PED's inherent risk to cause thrombotic complications, patients require a minimum of 6 months of dual antiplatelet therapy post-procedurally. The combination of aspirin with clopidogrel, ticlopidine, or prasugrel has shown to increase the risk of bleeding after PED deployment, particularly hemorrhaging of the gastrointestinal tract. The purpose of the study is to identify potential factors that contribute to an increased bleeding risk in order to reduce the incidence of gastric complications.

Methods: This retrospective, case-control study was approved by the Emory Institutional Review Board. A list of patients who underwent flow diversion with the pipeline embolization device at Emory University Hospital was used to identify eligible patients. Patients identified as having a gastrointestinal (GI) bleed comprised the case group. The control group was randomly selected from the same list of patients in a 2:1 ratio. Criteria for matching included age, gender, baseline platelet count, and baseline prothrombin time/ international normalized ratio (PT/INR). After the groups were established, data collection was preformed by chart review via Emory's electronic medical record system. Potential causative factors were identified and an odds ratio was calculated for each using an online statistics calculator application.

Results: Out of 218 total patients, 8 had a recorded GI bleed, therefore 16 patients created the control group. Using pantoprazole over famotidine as GI prophylaxis was associated with GI bleeding (odds ratio [OR] 8.25; 95% confidence interval [CI] 0.79 to 85.57; p= 0.077), as was a history of peptic ulcer disease (OR 9; 95% CI 0.75 to 107.39; p=0.082). GI bleeding was also associated with use of selective serotonin reuptake inhibitors (SSRIs), serotonin and norepinephrine reuptake inhibitors (SNRIs), or proton pump inhibitors (OR 4.3; 95% CI 0.67 to 28.12; p=0.124). Patients with subarachnoid hemorrhage were found to have an increased incidence of bleeding (OR 2.6; 95% CI 0.39 to 17.45; p=0.325). Of note, patients taking double dose antiplatelet agents were not found to have an association with bleeding (OR, 0.67; 95% CI 0.09 to 4.58; p=0.68). Lastly, near optimal or suboptimal PIPA scores for adenosine diphosphate (ADP) and arachadonic acid were associated with GI bleeding compared to those with optimal scores (OR 1.32; 95% CI 0.22 to 7.82; p=0.76; and OR 1.67; 95% CI 0.29 to 9.37; p=0.56, respectively).

Conclusion: Due to the small sample, the study was not adequately powered to find statistically significant results, however potential associations were discovered. Patients with below optimal PIPA scores, concurrent SSRIs/SNRIs, or GI prophylaxis with proton pump inhibitors were found to have an association with bleeding. A history of peptic ulcer disease or subarachnoid hemorrhage was also found to theoretically increase the risk of bleeding. It was established that the dose of antiplatelet agents did not have an effect on GI bleeding. Nevertheless, studies with a larger sample size must be completed to adequately assess these risk factors and determine their significance.

Poster Title: Mental health follow-up appointment adherence for long-acting injectable antipsychotic continuation after discharge from a psychiatric unit at a community teaching hospital in a rural area

Primary Author: McKinley King, University of Georgia College of Pharmacy, Georgia; **Email:** mking93@uga.edu

Additional Author (s):
Lauren Singletary
Jennifer Hafling
Stephanie Phan

Purpose: Patients with mental illness have a decreased likelihood of adherence to oral psychotropic therapies. Rates of adherence to treatment may be lower in rural communities. Long-acting injectable antipsychotics (LAIA) are intended to improve patient adherence and may be associated with shorter hospitalizations and relapses, however, benefits may not be realized if patients do not continue therapy. This study aims to identify rates of adherence to LAIA and follow-up appointments at a local mental health center post-discharge from a community teaching hospital in a rural area. Continuation of LAIA up to one year post-discharge was also evaluated.

Methods: This study is a retrospective, chart review of patients presenting at two facilities. Patients at least 18 years of age, discharged from the acute inpatient psychiatric unit at a community teaching hospital and initiated on a LAIA during hospitalization with follow-up appointments scheduled at the local county mental health center (MHC) were included in this study. Data obtained from patient charts included demographic data (age, sex, ethnicity, date of discharge, length of stay, diagnoses, insurance provider, marital status, legal status on admission, mode of arrival to psychiatric unit, living with children 18 years or younger, and employment status), the discharge medication list, 30-, 60-, and 90-day readmission status and emergency room presentation, documented nonadherence, date and time of follow-up appointments at the MHC, and adherence to appointments. Subsequent LAIA appointments and medication information for up to one year post-discharge was also obtained. The primary outcome was to examine rates of adherence to follow-up LAIA appointments by evaluating the

frequency in percent at which patients received their next scheduled LAIA dose. Factors describing patients based on LAIA adherence were characterized. Descriptive statistics were used to analyze patient demographics and the chi-square test was used to compare rates of adherence in patient subsets. This study was approved by the University and Hospital's institutional review board.

Results: Of 140 patients discharged between July and December 2014 with follow-up to the MHC, 26 patients received a LAIA during hospitalization. The average age was 41.7 years, with many patients being male, black, single, and diagnosed with psychotic disorders. This was not the first psychiatric hospitalization for approximately 75 percent of patients. Approximately 70 percent of all patients on LAIA had prior medication nonadherence documented. Forty percent of patients discharged on a LAIA received their first follow-up dose from the outpatient MHC. All patients were maintained on the same antipsychotic medication at their first appointment, and over half were maintained on the same dose. Of those continuing injections over a one-year time period post-discharge, an average of 8.7 injections were given and patients continued for an average of 8.5 months. Though patients were frequently maintained on the same medication, the dose and dosing frequency changed approximately 50 percent of the time. Over 90 percent of patients received haloperidol decanoate. Approximately 80 percent of patients were also discharged on oral medications in addition to the LAIA with an average of 1.6 oral medications. The overall average and median number of medications on discharge for all patients was 3.5 and 3, respectively.

Conclusion: Of patients discharged from a psychiatric unit at a community hospital on a LAIA with follow-up appointments at the county MHC, less than half of patients received the next LAIA dose. Of those who did continue LAIA therapy, none had their medication changed by the outpatient provider, though the dose may have been adjusted. Patients receiving the first outpatient LAI dose continued therapy for an average of 8 subsequent months over a year period. Further research should be conducted to identify barriers to adherence, including reasons for nonadherence, which may differ in rural areas, and effective strategies to target nonadherence.

Student Poster Abstracts

Poster Title: Evaluation of ertapenem use in a community hospital

Primary Author: Nathaniel Wayne, University of Georgia College of Pharmacy, Georgia; **Email:** nwayne10@uga.edu

Additional Author (s):
Barrett Darley

Purpose: The Infectious Diseases Society of America (IDSA) recommends cautious and appropriate use of antibiotics in order to decrease resistance and increase antibiotic lifespan. The purpose of this study was to evaluate ertapenem use during the first quarter of 2016 in a 181-bed community hospital in rural Georgia. Ertapenem is a broad-spectrum antibiotic covering certain gram-negative bacteria (including extended spectrum beta-lactamase (ESBL) producing bacteria), gram-positive bacteria, and anaerobes. The primary outcome was the appropriateness of use based on standard guidelines. Secondary outcomes included duration of use, drug-related adverse events, and length of stay.

Methods: The institutional review board approved this retrospective evaluation. The subjects were identified using a computer-generated list of all patients 18 years of age and older who received ertapenem from January 1, 2016 through March 31, 2016. The electronic medical record for each subject was accessed and de-identified data was collected including patient age and sex, drug allergies, history of drug-resistant bacterial infection, indication for use, dosages, duration of use, cultures and sensitivities, drug-related adverse events, and length of stay.

Results: During the 91-day study period, a total of seventy-six patients received at least one dose of ertapenem. The patient population was 60 percent female and had an average age of 53 years. Nine patients had a documented beta-lactam allergy. There were four patients with a documented history of infection with an ESBL-producing bacteria and ten total patients with a history of multi-drug resistant gram-negative rod infection. One patient had a previous infection of carbapenem-resistant enterobacteriaceae (CRE). Sixty patients received ertapenem under the indication of surgical prophylaxis. Other indications included osteomyelitis (1), skin and soft tissue infection (5), urinary tract infection with ESBL-producing bacteria (2), bacteremia (1), healthcare associated pneumonia (4), gunshot wound to the abdomen (2), and post-op

fever (1). The average duration of therapy was 2.4 days and the length of stay was 7 days. There were no drug-related adverse events recorded.

Conclusion: The majority of ertapenem used was prescribed under the indication of surgical prophylaxis. The ISDA guidelines for surgical prophylaxis recommend the use of cefazolin alone or cefazolin in combination with metronidazole for the majority of procedures. As medication experts, pharmacists are vital to improving antimicrobial stewardship efforts in health systems. Potential pharmacist-led interventions to promote guideline-based antibiotic selection for surgical prophylaxis include protocol development as well as prescriber education.

Poster Title: Evaluation of documentation of a pharmacy-driven vancomycin pharmacokinetic service at an academic medical center

Primary Author: Andrea Clarke, University of Georgia College of Pharmacy, Georgia; **Email:** clarke.andrea.m@gmail.com

Additional Author (s):
Paige Watkins
Andrea Sikora Newsome
Erinn Rowe

Purpose: While institutions address vancomycin dosing in a variety of ways, pharmacist documentation in the patient's medical record is a typical component of these services. The purpose of this evaluation is to determine how pharmacists currently document vancomycin pharmacokinetic service activities including timing and purpose of notes written, monitoring criteria included, and clinical rationale. Further, these practices were compared with the current protocol directing pharmacists to write notes for any recommendation to adjust or maintain a dose. Results of this evaluation will support quality improvement initiatives addressing the current limitations of the institution's pharmacokinetic consult service.

Methods: This study is a single-site retrospective review of pharmacy vancomycin dosing services at an academic medical center. Data included in this study were obtained from the records of patients who received at least four days of treatment with vancomycin between March 1 and April 30, 2016. The pharmacokinetic notes were evaluated to determine the timing and purpose of notes written, monitoring criteria included, and discussion of clinical thought process. This project was approved by the Augusta University institutional review board as a "not human subjects research". This project is also a part of the health system medication use evaluation (MUE) and improvement program.

Results: Of 38 patients evaluated, the median age and weight were 52.5 years and 81.7 kg, respectively. Fourteen patients were initiated on vancomycin in the intensive care unit and 24 on the general floor. Seven of 38 patients began pulse dosing due to renal dysfunction at some point during therapy. One pharmacokinetic note was written at initiation, documenting the

decision to base dosing on a prior vancomycin course during the patient's stay. Excluding times of pulse dosing, 80 troughs were drawn for which 63 had notes written (79 percent). Thirty-two changes in dose occurred, 28 of which had note documentation (88 percent). Decisions to maintain therapy were documented in 35 notes of 48 troughs for which no changes were made (73 percent). All notes included serum creatinine (SCr), creatinine clearance, and dialysis status. Five of 63 notes included calculated ke and Vd and estimated peak and trough (8 percent). Sixty-two notes included goal trough (98 percent), 4 included goal peaks (6 percent), and 8 documented when the next trough would be ordered (13 percent). Comments written often provided reasoning for why a dose was not changed despite sub- or supratherapeutic troughs such as being drawn early/late, missed dose, or elevated SCr.

Conclusion: The vancomycin monitoring protocol directs pharmacists to document any decision to change dose or maintain therapy. While this institution's pharmacists document dose changes the majority of the time (88 percent), they only document maintaining therapy 73 percent of the time. Few pharmacists include patient-specific pharmacokinetic parameters or goal/estimated peaks. Lack of a standardized template for clinical thought process leads to practice variation. Overall, adherence to current practice was considered appropriate; however, a revision of this institution's vancomycin monitoring protocol could provide pharmacists more direction on which patient details to include in pharmacokinetic notes, enabling more consistent documentation and patient care.

Poster Title: Mental health follow-up appointment adherence and factors associated with nonadherence after discharge from a psychiatric unit at a community teaching hospital in a rural area

Primary Author: Jennifer Hafling, University of Georgia College of Pharmacy, Georgia; **Email:** jhafling@uga.edu

Additional Author (s):
Lauren Singletary
McKinley King
Stephanie Phan

Purpose: Patients diagnosed with mental illness have high rates of nonadherence and poor attendance to follow-up appointments. Past research has shown that approximately 20-60% of patients are nonadherent. There is evidence that rates may be higher in rural communities. The period after psychiatric discharge is critical due to the high risk of rehospitalization. The purpose of this evaluation was to determine the rate of follow-up to the first outpatient mental health appointment after being discharged from a rural area inpatient psychiatric facility. Additionally, factors that predict nonadherence will be evaluated in order to identify strategies to improve post-discharge adherence and outcomes.

Methods: This study is a retrospective, chart review of patients in rural Georgia who were discharged between July and December 2014 from an acute inpatient psychiatric unit at a community teaching hospital with follow-up appointments at the local county mental health facility. Patients had to be at least 18 years old with a documented follow-up appointment at the local County Mental Health Center (MHC). Each patient's demographic information (sex, race, employment status, insurance, marital status, age, length of stay and legal status on admission), diagnoses, medication regimen (including total number of medications and class of medication), and readmission and/or emergency visit dates were recorded. The primary outcome measure was to identify the rate of patients who attended their outpatient follow-up appointment. Secondary outcomes included the identification of factors, based on previous literature searches, related to patient's nonadherence. Descriptive statistics were used to identify overall patient demographics. Chi-square tests were used to compare adherence in

pre-specified subsets and logistic regression was used to identify predictors of nonadherence. The study was approved by the university and hospital's institutional review board.

Results: A total of 140 patients were included in the study. Overall, substance use disorders were documented in 56.4 percent of patients, 20.7 percent had major depressive disorder and 22.9 percent had schizophrenia. Of the 140 patients, 133 had follow-up appointments scheduled at the time of discharge, with an average of 4.8 days between discharge and appointment. Thirty-six patients completed their follow-up appointment and 50 patients were no-shows. The remaining 54 patients either cancelled, rescheduled, partially completed their appointment or was not a documented patient at the MHC. Over 80 percent of those that were no shows were on a psychotropic of some kind. Seventy-two percent of those had a substance use disorder compared to 41.7 percent in the group that did complete their appointment (p=0.005). Among no-shows, 32 percent had major depressive disorder compared to 11.1 percent in the group that attended their appointment (p=0.024). The majority of patients that did attend appointments had schizophrenia (41.7 percent) and this was significantly different (p=0.004) compared to appointment no-shows. No difference was observed between patients discharged on any psychotropic between groups, though patients that completed appointments were more likely to be discharged on an antipsychotic or traditional mood stabilizer (p=not significant).

Conclusion: Approximately 35 percent of patients did not attend their follow-up appointment. While there appeared to be minimal to no differences among demographics between groups, the majority of patients that did not attend had a substance use disorder and/or major depressive disorder. This adherence data is consistent with past research, although further research is needed to identify generalizability of the study results and to identify effective strategies, such as targeting patients with specific psychiatric diagnoses, to overcome barriers to follow-up appointment adherence.

Poster Title: Transitions of care: Impact of the collaboration between inpatient and outpatient pharmacy on promoting improved quality of care

Primary Author: Michelle Morales, University of Georgia College of Pharmacy, Georgia; **Email:** mm218@uga.edu

Additional Author (s):
Brittany Bennett Wheeler
Jody Rocker

Purpose: As the outpatient bedside medication delivery program within an academic medical hospital, Meds2Bed, continues to expand in personnel and increased demand from patients and staff, so too does the potential to improve quality of care from admission to discharge. Therefore, this project evaluated the additional roles pharmacy personnel could adopt and the type of interventions emerging from Meds2Bed to identify areas for improvement and the overall impact of Meds2Bed, respectively. More specifically, data was gathered on the accuracy of patients' admission medication reconciliation and the interventions required on discharge medications for patients enrolled in this program.

Methods: This project is part of the institution's Medication Use Evaluation (MUE) and Improvement Program, which has been reviewed by the IRB and determined not to be human subject research. The clinical neuroscience pharmacist and pharmacist coordinator for the bedside medication delivery program at Augusta University Medical Center developed a data collection form to quantify the types of errors captured in medication reconciliations as well as the type of issues encountered on discharge prescriptions. Between July and September 2016, pharmacy students and two trained pharmacy technicians completed medication reconciliations for a sample of patients enrolled in the program. If available, patients' current medication reconciliation would be retrieved and then verified against the information gathered through patient interviews and, if needed, calling the patients' pharmacies. Any discrepancies on the medication reconciliations were recorded on the data collection forms and all necessary changes were then updated on patients' medical chart. The following types of errors were collected and analyzed on the data collection form: drug missing, wrong drug, wrong/no dose, wrong/no frequency, and no longer taking. These data points were used to

determine the accuracy of the medication reconciliation and where future interventions should occur. The frequency of prescription clarifications on sig, quantity, follow up on missing therapies, or other miscellaneous interventions were also collected to determine the impact of Meds2Bed involvement on discharge prescriptions.

Results: In total, 154 medication reconciliations were re-evaluated and 111 patients had their discharge prescriptions followed through until delivery. Results demonstrated that 71 percent of the medication reconciliations performed by non-pharmacy personnel were incomplete, meaning they were either missing parameters as defined above or had errors. Of 110 medication reconciliations deemed incomplete, a total of 184 discrepancies were found. To further stratify the results, the most frequent error found was drug missing (76) followed by wrong/no frequency (51), no longer taking (48), and wrong drug (9). The data that quantified discharge prescription interventions revealed that 27 out of 111 patients (24 percent) required clarifications on 47 issues. The most frequent clarification was other/miscellaneous (16) followed by sig (12), quantity (11), and missing therapy (8). The other/miscellaneous category represented a wide range of issues and no observed trends were noted.

Conclusion: A large proportion of the medication reconciliations observed in an academic medical center were found to be incomplete. This is an area that could be strengthened by pharmacy staff, especially if the pharmacy technician role is expanded to include medication reconciliation. A moderate amount of prescription clarifications were resolved by the Meds2Bed staff during this study, but the results are not likely an accurate reflection of the impact of this program due to underreporting.

Submission Type: Descriptive Report

Session-Board Number: 3-114

Poster Title: Pharmacist's contribution to Diabetic Care at a 200-Bed Community Hospital

Primary Author: John Stevick, University of Georgia College of Pharmacy, Georgia; **Email:** stevickj@uga.edu

Additional Author (s):
Titus Gates
Robin Southwood

Purpose: Diabetes is a common comorbidity encountered in the hospital setting. Diabetes care teams are commonly used to provide patient education, medication management, and positive treatment outcomes for diabetes. The benefits of a pharmacist as a component of the diabetes care team are poorly documented. This poster describes the contributions of a pharmacist as a member of a diabetes care team.

Methods: IRB approval was obtained. A Microsoft Access database stored on a secure network drive was used to store data on diabetes team interventions over a span of three years and 8 months (January 2013 through September 2016). The pharmacist contribution to these activities was separated and analyzed. This data included various activities ranging from drug therapy recommendations (insulin adjustments, protocol initiation, and medication changes). Pharmacists patient education activities were also recorded. Educational activities included discussing disease progression, risk factors, blood glucose monitoring, insulin dosing, and medication usage. Pharmacy students also contributed to the diabetes care team interventions under the direct supervision of the pharmacist. The student data was also analyzed in the same manner as previously mentioned and reported elsewhere. Discharge therapy from pre-pharmacist team membership in 2008 was compared to discharge data from 2016 to assess impact of pharmacist upon discharge therapy in patients with an A1c value greater than 8%.

Results: Pharmacist initiated 1318 diabetic protocols and documented 1812 educational patient encounters/interactions. Pharmacist also recommended 1976 insulin adjustments and 280 medication changes. 1316 of these recommendations were directed related to reducing risk of both hyperglycemia and hypoglycemia. Pharmacist also completed 29 hospitalist consults and made 2 dietary consult orders. Students under the supervision of the pharmacist suggested

2395 additional interventions. Data collected during the two comparison periods (September-October 2008/June 2016-September 2016) were compared using the Chi-Square test. The data was found to have 2 degrees of freedom, suggesting a moderate association. Analysis of discharge data indicates a significant impact of pharmacist involvement upon discharge therapy.

Conclusion: Pharmacist involvement was shown significant improvement in the care of patients with diabetes in a community hospital. Pharmacists may also improve prescribing of home medications for hospitalized patients with diabetes.

Poster Title: Ipratropium/albuterol inhaler medication use evaluation

Primary Author: Brandon Elpers, Butler University, Indiana; **Email:** belpers@butler.edu

Additional Author (s):
Bradley Carqueville
Danielle Thomas
Dalena Vo

Purpose: Ipratropium/albuterol metered-dose inhaler was removed from hospital order sets in 2015 due to cost concerns. The purpose of this medication utilization evaluation (MUE) was to identify areas to optimize the remaining use of ipratropium/albuterol during hospitalization within Community Health Network (CHNw). The MUE also sought to evaluate instances of medication underutilization and waste.

Methods: A retrospective chart review was approved by the institutional review board and performed using CHNw's electronic medical record. An Epic clarity dispense report was generated for ipratropium/albuterol inhaler usage from January 1, 2016 through May 31, 2016. Adult patients (18-89 years of age) who had a hospital order for ipratropium/albuterol inhaler were included in the MUE. The primary objective of the study was to identify the percent of inpatient orders for ipratropium/albuterol as a continuation of a home medication. Secondary objectives included: percent of patients who had ipratropium/albuterol ordered and/or dispensed but never received a dose during hospitalization, percent of doses used during hospitalization compared to number of doses available, and percent continuation upon discharge. Additional inhaled patient medications prior to admission and at discharge were also reviewed.

Results: Of the 197 patients reviewed, ipratropium/albuterol was a continued home medication for 145 patients compared to being a new order for 52 patients (73.6 percent v. 26.4 percent, respectively). Indications for medication use included COPD (59 percent), asthma (11.7 percent), both (12.2 percent), none (11.2 percent), and other (5 percent). Other indications included of shortness of breath, hypoxia, pneumonia, wheezing, and respiratory distress. Patients in whom the medication was dispensed but patient never received a dose occurred 37

percent of the time. In patients in which ipratropium/albuterol was dispensed but not returned or dispensed and administered, a mean of 6.2 doses (standard deviation 7.7) were given, respectively. Only 2 percent of patients used at least 25 percent of doses in the inhaler device. At discharge, 72.1 percent of patients received an order to continue ipratropium/albuterol. Of the patients who received a new order for ipratropium/albuterol during admission, only 32.7 percent (17/52) were prescribed a continuation upon discharge.

Conclusion: The majority of ipratropium/albuterol orders at CHNw are continuation of a home medication, however ipratropium/albuterol is frequently underutilized. On average, around five percent of available doses were given during admission, requiring CHNw to waste the remaining medication. An alternative formulation of ipratropium/albuterol is available as a single-dose nebulizer solution and may be the preferred substitution. The MUE findings, as well as the availability of a more cost-effective option, support the need for a pharmacy interchange or increased utilization of patient supplied medication.

Submission Type: Descriptive Report

Session-Board Number: 3-116

Poster Title: Rituximab use and cost saving analysis at an urban, safety-net hospital

Primary Author: Margaret Di Renzo, Butler University, Indiana; **Email:** mdirenzo@butler.edu

Additional Author (s):
Monica Macik

Purpose: Rituximab is a monoclonal antibody classified as an antineoplastic agent. Restriction criteria is in place to only be prescribed by authorized attending physicians under the scope of hematology/oncology, rheumatology, and dermatology. A formalized dose rounding protocol was initiated to prevent the use of partial vials and the wasting of medication. This medication use evaluation was performed to assess formulary restriction criteria, proper use, cost saving measures, and administrative setting.

Methods: This retrospective study included all patients in the inpatient and outpatient setting that received a rituximab infusion at Eskenazi Health during the study period of October 1, 2014 to May 31, 2015, which included 27 patients. Proper use of rituximab was assessed according to the FDA labeled use and listed off-label uses. Restriction criteria put into place by the institution was also evaluated. Primary endpoints include: administration according to the proper FDA indications, use of Eskenazi Health restriction criteria, and proper dosing and use of dose rounding protocol. Secondary endpoints include: total number of rituximab doses given, adverse reactions (significant fatigue, chest tightness, throat tightness, neutropenia, increased LFT, rigors), incidence of infusion rate pause and/or reduction, incidence of drug infusion discontinuation, administration setting, and number of total patients who received an infusion. A cost analysis was conducted to assess inpatient versus outpatient cost difference and dose rounding to nearest vial size in relation to cost savings.

Results: Over the study period, rituximab was used according to FDA labeled indications for 53% of infusions, 22% for listed off-label indications and 26% for non-listed indications. All patients were pre-medicated prophylactically with acetaminophen, diphenhydramine, + methylprednisolone. Minimal side effects were attributed to the use of rituximab with only 2 out of the 27 patients needing to decrease the rate of infusion due to infusion reactions. Only authorized physicians ordered rituximab, which followed the restriction criteria. There was 1

incidence of improper rounding. The dose was rounded twice, once by the prescriber and once by the pharmacist leading to an increased dose for the patient. However, no harm resulted. The average number of infusions per month was 12.5. All patients who received rituximab were in the outpatient setting; leading to cost saving measures for the hospital and patients due to 340B contracted pricing. The institution saved $249,673 over 6 months by giving all doses in the outpatient setting. Rounding doses to the next whole vial lead to the savings of $9,401.26.

Conclusion: Overall, this study demonstrated that the majority of rituximab doses were administered in accordance with FDA labeled indications or listed off-label uses. Prescribers were compliant with restriction criteria; only authorized physicians prescribed this medication. Dose rounding to the nearest 100mg was completed accurately with the exception of one occurrence. Due to low incidence of adverse effects and cost effectiveness, no further prescribing or administration restriction additions are planned at this time.

Submission Category: Drug-Use Evaluation/ Drug Information

Submission Type: Evaluative Study

Session-Board Number: 3-117

Poster Title: Evaluation of an Alternate Dosing Strategy for Intravenous Levothyroxine in the Hospital

Primary Author: Adam Rominger, Butler University, Indiana; **Email:** arominge@butler.edu

Additional Author (s):
Christie Bertram
Kelly Davidson
Sarah Lowry
Lindsay Saum

Purpose: Levothyroxine has a half-life of 6.3 days in euthyroid patients and 7.5 days in hypothyroid patients. The resulting studies show TSH levels remain therapeutic for 7 days after withdrawal of levothyroxine with no difference in cardiovascular complications, indicating no need to immediately transition an oral dose to intravenous. The purpose of this study is to evaluate compliance and clinical outcomes to an Ascension Health initiative protocol directed at cost reduction utilizing alternative dosing regimen that starts intravenous levothyroxine 72 hours after last oral dose and given every 72 hours for 2 doses, then daily administration is started on day 7.

Methods: An IRB-approved retrospective chart review conducted on patients, 18 and older, admitted to St. Vincent Indianapolis Hospital between 3/1/2014 and 5/31/2016 and received at least one dose of intravenous levothyroxine. The primary outcome of this study was to evaluate the overall compliance to the protocol, including appropriate conversion from oral to intravenous dose, initial intravenous dose administered at the correct time frame (3 days after last oral dose), utilization of the order set with both intravenous orders selected (every 72 hours x 2 doses and daily starting on day 7), and exclusion criteria followed per protocol. The exclusion criteria of the protocol includes myxedema coma, organ donation, clinical hypothyroidism (TSH of 10 or greater), strict NPO without enteral access for 7 or more days, and pregnant women. The secondary outcome was to evaluate the incidence of clinical outcomes, which were defined as an elevation of TSH within three months of discharge and readmission within 30 days. Patients' electronic medical records were reviewed to capture age, gender, baseline TSH and T4, home and inpatient intravenous dose, intravenous levothyroxine

prescriber, date last oral dose was received, date intravenous ordered and initial intravenous dose given, total number of intravenous doses given, use of both order sets, if patient fit any protocol exclusion criteria, readmission within 30 days of discharge, and subsequent TSH levels within three months of discharge.

Results: A total of 412 intravenous levothyroxine orders were evaluated, producing 279 orders received by patients. Forty-two orders were excluded per protocol, resulting in 120 following and 117 not following protocol. The 237 included orders per protocol for final evaluation displayed an overall protocol compliance of 50.6%.The largest area of protocol noncompliance (n=98) was due to receipt of the intravenous dose within 72 hours of stopping oral levothyroxine.. Additional reasons for noncompliance were incorrect order set use (n=15) and intravenous dose (n=4). Twenty orders (16%) that followed the protocol were readmitted within 30 days compared to 14 orders (12%) that did not follow the protocol. In examining TSH levels 3 months after discharge, 14 (12%) and 19 (16%) patients had a follow up TSH in the protocol and non-protocol groups respectively. There were low rates of abnormal follow up TSH, 1 patient in the protocol group and 5 in the non-protocol group; however none of these patients had a baseline TSH to determine any significant changes due to the alternative dosing strategy.

Conclusion: Intravenous levothyroxine protocol evaluation identified areas for continued improvement and education. Overall, protocol compliance was lacking, therefore cost reduction could be further refined. Clinical outcomes were not significantly different between the groups however, this study is not powered or designed to determine significance. This highlights the importance of future studies evaluating clinical outcomes with alternative dosing strategies.

Poster Title: Impact of pharmacy student-led teaching during a short-term medical mission trip to the Dominican Republic

Primary Author: Jasmine Coatie, Butler University College of Pharmacy, Indiana; **Email:** jcoatie@butler.edu

Additional Author (s):
Bethany Feitshans
Andrea Baker
Ryan Barton
Thomas Muma

Purpose: Opportunities for student involvement in global health initiatives and student participation on short-term medical mission trips have been increasing over the past years. There is not literature to support the use of student-led education on medical mission trips, however this teaching technique has proven to be effective in other settings. Because pharmacy students are trained and well-equipped to provide impactful teaching, they present an opportunity to bridge the education gap on medical mission trips. The objective of this study was to assess if pharmacy student-led education improves health professional knowledge on medical mission trips.
