Assessment of Evidence for COVID-19-Related Treatments: Updated 5/21/2020

The information contained in this evidence table is emerging and rapidly evolving because of ongoing research and is subject to the professional judgment and interpretation of the practitioner due to the uniqueness of each medical facility’s approach to the care of patients with COVID-19 and the needs of individual patients. ASHP provides this evidence table to help practitioners better understand current approaches related to treatment and care. ASHP has made reasonable efforts to ensure the accuracy and appropriateness of the information presented. However, any reader of this information is advised ASHP is not responsible for the continued currency of the information, for any errors or omissions, and/or for any consequences arising from the use of the information in the evidence table in any and all practice settings. Any reader of this document is cautioned that ASHP makes no representation, guarantee, or warranty, express or implied, as to the accuracy and appropriateness of the information contained in this evidence table and will bear no responsibility or liability for the results or consequences of its use.

Public access is currently available to AHFS Drug Information® (https://www.ahfscdi.com/login) with the username "ahfs@ashp.org" and password "covid-19." ASHP’s patient medication information is available at http://www.safemedication.com/.

</tbody>
</table>
| and 5 with severe COVID-19) received LPV/RTV (lopinavir 400 mg/ritonavir 100 mg twice daily for 10 days). All 10 pts treated with chloroquine had negative RT-PCR results for SARS-CoV-2 by day 13 and were discharged from the hospital by day 14; 11/12 pts (92%) treated with LPV/RTV were negative for SARS-CoV-2 at day 14 and only 6/12 (50%) were discharged from the hospital by day 14. **Note:** Results suggest that chloroquine was associated with shorter time to RT-PCR conversion and quicker recovery than LPV/RTV; however, this study included a limited number of pts and the median time from onset of symptoms to initiation of treatment was shorter in those treated with chloroquine than in those treated with LPV/RTV (2.5 vs 6.5 days, respectively).<sup>20</sup>  
**Double-blind randomized phase 2b study in Brazil (Borba et al) to evaluate two different chloroquine dosages as adjunctive therapy in hospitalized adults with severe COVID-19 (NCT04323527):** The first 81 enrolled pts were randomized 1:1 to receive high-dose chloroquine (600 mg twice daily for 10 days) or lower-dose chloroquine (450 mg twice daily on day 1, then 450 mg once daily on days 2-5); all pts also received azithromycin and ceftriaxone and some also received oseltamivir. An unplanned interim analysis was performed and the high-dose arm of the study was halted because of toxicity concerns, particularly QTc prolongation and ventricular tachycardia, and because more deaths were reported in this arm. By day 13, 16/41 pts (39%) treated with the high-dose regimen had died vs 6/40 (15%) treated with the lower-dose regimen. QTc >500 msec occurred more frequently in the high-dose group (18.9%) than in the lower-dose group (11.1%). The high-dose arm included more pts prone to cardiac complications than the lower-dose arm. Data were insufficient to evaluate efficacy. Study continuing using only the lower dosage. <sup>27</sup>  
Multiple clinical trials to evaluate chloroquine for the treatment of COVID-19 are total treatment based on clinical evaluation. <sup>25</sup>  
**Oral chloroquine phosphate dosage in Chinese guidelines:** 500 mg twice daily for 7 days (adults 18-65 years weighing >50 kg); 500 mg twice daily on days 1 and 2, then 500 mg once daily on days 3-7 (adults weighing <50 kg). <sup>11</sup>  
**Oral chloroquine phosphate:** Initial dose of 600 mg (of chloroquine) followed by 300 mg (of chloroquine) 12 hours later on day 1, then 300 mg (of chloroquine) twice daily on days 2-5. <sup>4</sup>  
Chloroquine suggested as possible option and included in Chinese guidelines for treatment of COVID-19. <sup>17</sup>  
**NIH COVID-19 Treatment Guidelines** Panel states that clinical data are insufficient to recommend either for or against the use of chloroquine for the treatment of COVID-19; the panel recommends against use of high-dose chloroquine (i.e., 600 mg twice daily for 10 days) because such dosage has been associated with more severe toxicities compared with lower-dose chloroquine. <sup>35</sup>  
**IDSA recommends that chloroquine be used for the treatment of COVID-19 in the context of a clinical trial.** <sup>38</sup> IDSA recommends that a combined regimen of chloroquine and azithromycin be used for the treatment of COVID-19 only in the context of a clinical trial. <sup>38</sup>  
**NIH COVID-19 Treatment Guidelines** Panel does not recommend the use of any agents, including chloroquine, for preexposure prophylaxis (PrEP) or postexposure prophylaxis (PEP) for prevention of SARS-CoV-2 infection outside of clinical trials. <sup>35</sup>  
Because chloroquine is associated with QT prolongation, caution is advised in pts at risk for QT prolongation or receiving other drugs associated with arrhythmias; <sup>13, 17, 36, 39</sup> diagnostic testing and monitoring recommended to minimize risk of adverse effects, including drug-induced cardiac effects. <sup>35, 36, 39</sup> (See Hydroxychloroquine in this Evidence Table.)  
**FDA issued a safety alert regarding adverse cardiac effects (e.g., prolonged QT interval, ventricular tachycardia, ventricular fibrillation) reported with use of chloroquine or hydroxychloroquine (either alone or in conjunction with azithromycin or other drugs known to prolong QT interval) in hospital and**

| Favipiravir (Avigan®, Favilavir) | 8:18.32 Antiviral | Broad-spectrum antiviral with in vitro activity against various viruses, including coronaviruses 1-5 | Registered at clinicaltrials.gov (some listed below): 10  
NCT04323527  
NCT04328493  
NCT04331600  
NCT04333628  
NCT04353336  
NCT04360759  
NCT04362332  
Several clinical trials to evaluate chloroquine for prevention of COVID-19 in the healthcare setting are registered at clinicaltrials.gov: 10  
NCT04303507  
NCT04333732  
NCT04349371  
In vitro evidence of activity against SARS-CoV-2 in infected Vero E6 cells reported with high concentrations of the drug 1,5,16  
Licensed in Japan and China for treatment of influenza 1,4,6  
Only very limited clinical trial data available to date to evaluate use of favipiravir in the treatment of COVID-19  
Open-label, prospective, randomized, multicenter study in 236 adults with COVID-19 pneumonia in China (ChiCTR2000030254): Favipiravir (1600 mg orally twice daily on day 1, then 600 mg orally twice daily thereafter for 7–10 days) was associated with greater clinical recovery rate at 7 days (61 vs 52%) compared with the control group treated with umifenovir (Arbidol®; 200 mg 3 times daily)  
A favipiravir dosage of 1600 mg twice daily on day 1, then 600 mg twice daily thereafter for 7–10 days was used in one open-label COVID-19 study 6  
A favipiravir dosage of 1600 mg twice daily on day 1, then 600 mg twice daily thereafter for 14 days was used in one open-label COVID-19 study 15  
Protocol in one ongoing trial (NCT04336904) for treatment of moderate COVID-19 specifies a dosage of 1600 mg twice daily for 5 days  
A favipiravir dosage of 1600 mg twice daily for 7 days was used in an ongoing trial (NCT04363038)  
Not commercially available in the US  
Efficacy and safety of favipiravir for treatment of COVID-19 not established  
Additional data needed to substantiate initial reports of efficacy for treatment of COVID-19 and identify optimal dosage and treatment duration  
Given the lack of pharmacokinetic and safety data for the high favipiravir dosages proposed for treatment of COVID-19, the drug should be used with caution | Outpatient settings; FDA cautions against use of chloroquine or hydroxychloroquine outside of a clinical trial or hospital setting and urges healthcare professionals and pts to report adverse effects involving these drugs to FDA MedWatch. 39  
Emergency use authorization (EUA) for chloroquine: FDA issued an EUA that permits distribution of the drug from the strategic national stockpile (SNS) for use only in adults and adolescents weighing 50 kg or more hospitalized with COVID-19 for whom a clinical trial is not available or participation not feasible. 24,25  
To request the drug, healthcare providers should contact local or state health departments; distribution to states will be managed by the Office of the Assistant Secretary for Preparedness and Response (ASPR) and FEMA. 29  
To mitigate risks of this unapproved use, the EUA includes certain mandatory requirements (including adverse event reporting to FDA MedWatch). 24,25  
FDA states that, based on the totality of scientific evidence available, it is reasonable to believe that the drug may be effective in treating COVID-19 and that, when used under the EUA conditions, known and potential benefits outweigh known and potential risks. 24  
Consult the EUA, 24 EUA fact sheet for healthcare providers, 25 and EUA fact sheet for patients and parent/caregivers for additional information. 27

<tr>
<td>Favipiravir</td>
<td></td>
<td></td>
<td>for 7–10 days. Stratifed by disease severity, clinical recovery rate at day 7 in pts with moderate COVID-19 pneumonia was 71% in the favipiravir group vs 56% in the umifenovir group; clinical recovery rate in those with severe to critical COVID-19 pneumonia was 6% vs 0%, respectively. Twice as many pts in the favipiravir group had severe to critical disease compared with the group receiving umifenovir.</td>
<td>Favipiravir dosage of 1800 mg twice daily on day 1, then 600 mg three times daily thereafter for up to 14 days</td>
<td>caution at such dosages.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>In a small, open-label, nonrandomized study in patients with non-severe COVID-19 in China (ChiCTR2000029600), favipiravir (1600 mg orally twice daily on day 1, then 600 mg orally twice daily on days 2–14 (n=35) was associated with decreased median time to viral clearance (4 vs 11 days) and higher improvement rate on chest CT imaging on day 14 (91 vs 62%) compared with the control group receiving lopinavir/ritonavir (n=45); both groups also received aerosolized interferon α-1b.</td>
<td>Protocol in one ongoing trial (NCT04346628) for treatment of mild COVID-19 specifies a favipiravir dosage of 1800 mg on day 1, then 800 mg twice daily on days 2–10.</td>
<td>Some have suggested close cardiac and hepatic monitoring during treatment, as well as monitoring of plasma and tissue concentrations of the drug and, if possible, the active metabolite. Some data suggest favipiravir exposure may be greater in Asian populations.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Italy: Randomized, placebo-controlled multicenter trial (NCT04336904) to evaluate efficacy and safety of favipiravir in pts with moderate COVID-19.</td>
<td>Protocol in one ongoing trial (NCT04349241) for treatment of non-severe COVID-19 specifies a favipiravir dosage of 1600 mg every 12 hours on day 1, then 600 mg every 12 hours on days 2–10.</td>
<td>Early embryonic deaths and teratogenicity observed in animal studies. Favipiravir is contraindicated in women with known or suspected pregnancy and precautions should be taken to avoid pregnancy during treatment with the drug.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>US: Randomized, controlled open-label proof-of-concept trial (NCT04358549) of favipiravir for the treatment of COVID-19.</td>
<td>Protocol in one ongoing trial (NCT04358549) for treatment of COVID-19 specifies a favipiravir dosage of 1800 mg twice daily on day 1, then 1000 mg twice daily on days 2–14.</td>
<td>If favipiravir is used in pts receiving acetaminophen, the maximum recommended daily dosage of acetaminophen is 3 g.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>US: Randomized, open-label trial (NCT04346628) to evaluate efficacy of favipiravir in pts with mild, uncomplicated COVID-19.</td>
<td>Protocol in one ongoing trial (NCT04373733; PIONEER) for early treatment of suspected or confirmed COVID-19 specified a favipiravir dosage of 1800 mg twice daily on day 1, followed by 800 mg twice daily on days 2–10.</td>
<td>Because high favipiravir concentrations are required for in vitro activity against SARS-CoV-2, it has been suggested that high favipiravir dosages, like those used in the treatment of Ebola virus disease, should be considered for the treatment of COVID-19.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Multiple clinical trials initiated in pts with COVID-19 in China, Japan, and other countries to evaluate favipiravir alone or in conjunction with other antivirals or other agents (some listed below):</td>
<td>One such favipiravir regimen used in the treatment of Ebola virus disease includes a loading dosage of 6000 mg (doses of 2400 mg, 2400 mg, and 1200 mg given 8 hours apart on day 1), then a maintenance dosage of 1200 mg every 12 hours on days 2–10.</td>
<td>One pharmacokinetic simulation model suggested that a dosage of 2400 mg twice daily on day 1, followed by 1600 mg twice daily on days 2–10.</td>

Updated 5-21-20. The current version of this document can be found on the ASHP COVID-19 Resource Center. This work is licensed under a Creative Commons Attribution-NonCommercial 4.0 International License.
and 5 with severe disease) received LPV/RTV (lopinavir 400 mg/ritonavir 100 mg twice daily for 10 days). All 10 pts treated with chloroquine had negative RT-PCR results for SARS-CoV-2 by day 13 and were discharged from the hospital by day 14; 11/12 pts (92%) treated with LPV/RTV were negative for SARS-CoV-2 at day 14 and only 6/12 (50%) were discharged from the hospital by day 14. **Note:** Results suggest that chloroquine was associated with shorter time to RT-PCR conversion and quicker recovery than LPV/RTV; however, this study included a limited number of pts and the median time from onset of symptoms to initiation of treatment was shorter in those treated with chloroquine than in those treated with LPV/RTV (2.5 vs 6.5 days, respectively).  

**LPV/RTV with ribavirin and interferon β-1b vs LPV/RTV alone in open-label, randomized trial in adults with mild to moderate COVID-19 in Hong Kong (Hung et al; NCT04276688):** 127 pts were randomized 2:1 to receive LPV/RTV (LPV 400 mg/RTV 100 mg) twice daily for 14 days) with ribavirin (400 mg twice daily) and interferon β-1b (8 million IU sub-Q on alternate days for up to 3 doses depending on how soon treatment initiated after symptom onset) or a 14-day regimen of LPV/RTV alone. Median time to negative RT-PCR results for SARS-CoV-2 in nasopharyngeal samples was 7 days in pts treated with the 3-drug regimen vs 12 days in those treated with LPV/RTV alone; median duration of hospitalization was 9 or 14.5 days, respectively. Adverse effects reported in 48% of those treated with the 3-drug regimen and in 49% of those treated with LPV/RTV alone. **Note:** Results indicate a 3-drug regimen that included LPV/RTV, ribavirin, and interferon β-1b was more effective than LPV/RTV alone in pts with mild to moderate COVID-19, especially when treatment was initiated within 7 days of symptom onset.  

**LPV/RTV retrospective cohort study in China (Deng et al) evaluated use of LPV/RTV with or without umifenovir (Arbidol®) in adults. Primary end point was negative**

<td></td>
</tr>
<tr>
<td>Hydroxychloroquine randomized, parallel-group, open-label study in hospitalized adults with mild to moderate COVID-19 in China (ChiCTR2000029868): 150 pts (148 with mild to moderate disease and 2 with severe disease) were randomized 1:1 to receive hydroxychloroquine (1200 mg daily for 3 days, then 800 mg daily for total treatment duration of 2-3 weeks) with standard of care or standard of care alone. Mean time from onset of symptoms to randomization was 16.6 days (range: 3-41 days). Standard of care included IV fluids, O₂, various antivirals (e.g., umifenovir, LPV/RTV), antibiotics, and/or glucocorticoid therapy. By day 28, 73% of pts (53 treated with hydroxychloroquine with standard of care and 56 treated with standard of care alone) had converted to negative for SARS-CoV-2. The probability of negative conversion by day 28 in those treated with hydroxychloroquine was similar to that in those treated with standard of care alone; the median time to negative seroconversion (6 and 7 days) also was similar in both groups. Adverse effects reported in 30% of those treated with hydroxychloroquine and 9% of those treated with standard of care alone. Note: Results indicate that use of hydroxychloroquine in pts with mild to moderate COVID-19 did not provide additional benefits compared with use of standard of care alone. 32</td>

| Hydroxychloroquine with azithromycin open-label, nonrandomized study in France (Gautret et al): |            | Preliminary data from an ongoing study in hospitalized pts with confirmed COVID-19 was used to assess efficacy of hydroxychloroquine used alone or with azithromycin; untreated pts were used as a negative control. The primary end point was negative PCR results in nasopharyngeal samples at day 6. Data from 14 pts treated with hydroxychloroquine sulfate (200 mg 3 times daily for 10 days), 6 pts treated with hydroxychloroquine and azithromycin (500 mg on day 1, then 250 mg daily on days 2-5), and 16 pts in the control group were analyzed. At day 6, 8/14 (57%) in the hydroxychloroquine group, 6/6 (100%) in the hydroxychloroquine and azithromycin group, and 2/16 (12.5%) in the control group had negative PCR results. At day 8, a positive PCR was reported in a pt treated with both drugs who had tested negative at day 6.  
**Note:** This was a small nonrandomized study that didn’t appear to be designed to compare hydroxychloroquine vs hydroxychloroquine and azithromycin (pts received antibiotics to prevent bacterial superinfection based on clinical judgment). Data on disease severity were unclear (some asymptomatic pts were included when study initiated) and information on disease progression and clinical outcomes was not presented. |                                                                                                                                  |                                                                                                                                  | conditions, known and potential benefits outweigh known and potential risks.  
24 Consult the EUA, EUA fact sheet for healthcare providers, and EUA fact sheet for patients and parent/caregivers for additional information.                                                                                                    |
| Hydroxychloroquine with azithromycin open-label, uncontrolled study in France (Molina et al): |            | 11 adults hospitalized with COVID-19 received hydroxychloroquine (600 mg daily for 10 days) and azithromycin (500 mg on day 1, then 250 mg daily on days 2-5). At time of treatment initiation, 8/11 pts had significant comorbidities associated with poor outcomes and 10/11 had fever and received O₂. Within 5 days, 1 pt died and 2 transferred to ICU; the regimen was discontinued in 1 pt after 4 days because of prolonged QT interval. Nasopharyngeal samples were still PCR positive at days 5 and 6 in 8/10 pts tested.  
**Note:** In this small uncontrolled study, hydroxychloroquine and azithromycin regimen did not result in rapid viral clearance or provide clinical benefit.                                                                 |                                                                                                                                  |                                                                                                                                  |

<td>Hydroxychloroquine with azithromycin</td>
<td></td>
<td></td>
<td>uncontrolled, retrospective, observational study in France (Gautret et al): 80 adults with confirmed COVID-19 (including 6 pts included in a previous study by the same group) were treated with hydroxychloroquine sulfate (200 mg 3 times daily for 10 days) and azithromycin (500 mg on day 1, then 250 mg daily on days 2-5). Majority (92%) were considered low risk for clinical deterioration (low national early warning score for COVID-19 based on age, respiratory rate, O_{2} saturation, temperature, BP, pulse, level of consciousness); only 15% had fever; 4 pts were asymptomatic carriers; mean time from onset of symptoms to treatment initiation was 4.9 days. Clinical outcome, contagiousness as assessed by nasopharyngeal PCR assay and culture, and length of stay in infectious disease (ID) unit were evaluated in pts who were treated for at least 3 days and followed for at least 6 days. Favorable outcome was reported for 81.3%; 15% required O_{2}; 3 pts transferred to ICU; 1 pt died; mean time to discharge from ID unit was 4.1 days. At day 8, PCR results were negative in 93% of those tested; at day 5, viral cultures were negative in 97.5% of those tested. Note: Almost all pts were considered low risk for clinical deterioration (including 4 pts described as asymptomatic carriers) and it is unclear how many would have had spontaneous conversion to negative nasopharyngeal samples during same time frame. Although 80 pts were enrolled, PCR results available for fewer pts beginning on day 3 and only 60 pts represented in day 6 data. This was an uncontrolled study and data presented cannot be used to determine whether a regimen of hydroxychloroquine with azithromycin provides benefits in terms of disease progression or decreased infectiousness, especially for pts with more severe disease.</td>

</tbody>
</table>
times daily for 10 days) and azithromycin (500 mg on day 1, then 250 mg daily on days 2-5) were analyzed for clinical outcomes and persistence of viral shedding. Pts were included in the analysis if they received the combined regimen for at least 3 days and were clinically assessable at day 9. There were 56 asymptomatic and 1005 symptomatic pts; the majority (95%) had relatively mild disease and were considered low risk for clinical deterioration; median age was 43.6 years (range: 14-95 years) and mean time between onset of symptoms and initiation of treatment was 6.4 days. Within 10 days of treatment, good clinical outcome reported in 973 pts (91.7%) and poor clinical outcome reported in 46 pts (4.3%). Persistent nasal carriage of SARS-CoV-2 reported at completion of treatment in 47 pts (4.4%); 8 pts died.47

Hydroxychloroquine (with or without azithromycin) in a retrospective analysis of patients hospitalized with COVID-19 in US Veterans Health Administration medical centers (Magagnoli et al): Data for 368 males (median age >65 years) treated with hydroxychloroquine in addition to standard supportive management were analyzed for death rate and need for mechanical ventilation. Death rate was 27.8% (27/97) in those treated with hydroxychloroquine, 22.1% (25/113) in those treated with hydroxychloroquine and azithromycin, and 11.4% (18/158) in those not treated with hydroxychloroquine; rate of ventilation was 13.3, 6.9, and 14.1%, respectively. Use of hydroxychloroquine alone (but not use of hydroxychloroquine and azithromycin) was associated with increased overall mortality compared with no hydroxychloroquine; use of hydroxychloroquine with or without azithromycin did not reduce the risk of mechanical ventilation.40 Note: The pt population included only elderly males 59-75 years of age, many with significant comorbidities. This analysis did not look at efficacy measures. Two different retrospective studies analyzed outcome data for hospitalized pts
with confirmed COVID-19 in New York to assess the effects of treatment with hydroxychloroquine with or without azithromycin: Rosenberg et al analyzed data for 1438 pts (735 received hydroxychloroquine with azithromycin, 271 received hydroxychloroquine alone, 211 received azithromycin alone, 221 received neither drug) and assessed in-hospital mortality (primary outcome). Overall, in-hospital mortality was 20.3%; in-hospital mortality was 25.7, 19.9, 10, or 12.7% in those treated with hydroxychloroquine with azithromycin, hydroxychloroquine alone, azithromycin alone, or neither drug, respectively. Geleris et al analyzed data for 1376 pts (811 received hydroxychloroquine [486 of these also received azithromycin] and 565 did not receive hydroxychloroquine [127 of these received azithromycin]) and assessed the primary end point of time from study baseline to intubation or death. Overall, 346 pts (25.1%) progressed to a primary end point of intubation and/or death and the composite end point of intubation or death was not affected by hydroxychloroquine treatment (intubation or death reported in 32.3% of pts treated with hydroxychloroquine and 14.9% of pts not treated with the drug). Note: Results of both studies suggest that use of hydroxychloroquine with or without azithromycin is not associated with decreased in-hospital mortality. 45, 46

**Efficacy measures:** Initial studies evaluating hydroxychloroquine based efficacy of the drug on negative conversion in nasopharyngeal samples at day 6 or 7. RT-PCR tests using upper and lower respiratory specimens (including nasopharyngeal and oropharyngeal swabs) are recommended for diagnosis of COVID-19; however, dynamics of SARS-CoV-2 in infected patients (untreated or treated) and presence of the virus at various body sites over the course of infection have not been fully determined. 22, 23

**Hydroxychloroquine with azithromycin** randomized, double-blind, placebo-controlled trial sponsored by NIAID

Broad-spectrum antiviral (nucleotide analog prodrug) with activity against various viruses, including coronaviruses<sup>24</sup>

In vitro evidence of activity against SARS-CoV-2 in Vero E6 cells<sup>1,18</sup>

In Rhesus macaques infected with SARS-CoV-2, treatment with a 6-day regimen of IV remdesivir initiated 12 hours after virus inoculation was associated with some benefits (lower disease severity scores, fewer pulmonary infiltrates, lower virus titers in bronchoalveolar lavage samples) compared with vehicle control; remdesivir treatment did not reduce viral loads or infectious virus titers in nose, throat, or rectal swabs compared with vehicle control<sup>19</sup>

In vitro activity against SARS-CoV and MERS-CoV; active in animal models of SARS and MERS; prevented MERS in Rhesus macaques when given before infection and provided benefits when given after animal already infected<sup>1,8</sup>

Oseltamivir is effective in the treatment of COVID-19.<sup>2</sup>

Neither oseltamivir nor zanamivir has demonstrated inhibition of cytopathic effect against SARS-CoV in vitro cell culture.<sup>4</sup>

Clinicaltrials.gov trials for COVID-19 that include oseltamivir:<nCT04303299
NCT04261270
NCT04255017
NCT04383698

Randomized, double-blind, placebo-controlled trial in hospitalized adults with severe COVID-19 in China (NCT04257656; Wang et al): Pts were randomized 2:1 to receive remdesivir (200 mg IV on day 1, then 100 mg IV once daily on days 2-10) or placebo initiated within 12 days of symptom onset. Primary outcome was time to clinical improvement within 28 days after randomization or hospital discharge, whichever came first. ITT population included 158 pts treated with remdesivir and 78 pts treated with placebo; 32% of pts also received interferon α-2b, 28% also received LPV/RTV, and 66% also received corticosteroids during hospitalization. Median time to clinical improvement was not significantly different in remdesivir group (21 days) vs placebo group (23 days); 28-day mortality rate was similar in both groups (14 vs 13%). When remdesivir was initiated within 10 days of symptom onset, median time to clinical improvement was numerically shorter (but not statistically significant) compared with placebo group (18 vs 23 days). Duration of invasive mechanical ventilation was numerically shorter (but not statistically significant) in remdesivir group; only a small percentage of pts (0.4%) were on invasive mechanical ventilation at time of enrollment. Remdesivir did not result in significant reduction in SARS-CoV-2 viral load in nasopharyngeal, oropharyngeal, and sputum samples. Remdesivir was discontinued in 18 pts (12%) because

Optimal dosage and duration of treatment not known<sup>25,26</sup>

Phase 3 trial protocol (severe COVID-19): 200 mg IV on day 1, then 100 mg IV daily on days 2-5 (arm 1) or 200 mg IV on day 1, then 100 mg IV daily on days 2-10 (arm 2);<sup>10</sup> 200 mg IV on day 1, then 100 mg IV daily on days 2-10 (extension arms that include pts who are or are not receiving mechanical ventilation)<sup>10</sup>

Phase 3 trial protocol (moderate COVID-19): 200 mg IV on day 1, then 100 mg IV on days 2-5 (arm 1) or 200 mg IV on day 1, then 100 mg IV daily on days 2-10 (arm 2)<sup>11</sup>

NIAD adaptive study protocol: 200 mg IV on day 1, then 100 mg IV for duration of hospitalization up to 10 days total<sup>13</sup>

Compassionate use access protocol: 200 mg IV on day 1, then 100 mg IV on days 2-10<sup>16</sup>

Emergency use authorization (EUA) for remdesivir: FDA issued an EUA on May 1, 2020 that permits use of the drug for the treatment of COVID-19 only in hospitalized adults and children with suspected or laboratory-confirmed COVID-19 who have severe disease (defined as oxygen saturation [SpO₂] 94% or lower on room air or requiring supplemental oxygen, mechanical ventilation, or ECMO) and requires that the drug be administered by a healthcare provider in an inpatient hospital setting via IV infusion at dosages recommended in the EUA.<sup>25,26</sup> Distribution of remdesivir under this EUA is controlled by the US government for use consistent with the terms and conditions of the EUA.<sup>25,26</sup> The manufacturer (Gilead) donated remdesivir for use under the EUA; distribution to hospitals and other healthcare facilities is being directed by the HHS.

Updated 5-21-20. The current version of this document can be found on the [ASHP COVID-19 Resource Center](https://ashp.covid19.resourcecenter.org/). This work is licensed under a [Creative Commons Attribution-NonCommercial 4.0 International License](https://creativecommons.org/licenses/by-nc/4.0/).
Phase 3 adaptive, randomized, placebo-controlled trial (NCT04280705; ACTT) in hospitalized adults sponsored by NIAID: Pts received remdesivir (200 mg IV on day 1, then 100 mg once daily for duration of hospitalization up to 10 days total) or placebo. Sponsor announced that preliminary data analysis (total of 1063 pts) indicated shorter median time to recovery in remdesivir group (11 days) vs placebo group (15 days) and suggested that remdesivir treatment may have provided a survival benefit (mortality rate 8% in remdesivir group vs 11.6% in placebo group). Note: Data regarding the pt population (e.g., disease severity and comorbidities at study enrollment, time to initiation of treatment after symptom onset, additional supportive treatment received) not provided to date.

Expanded access IND protocol (NCT04323761): The manufacturer (Gilead) established a protocol for emergency access to remdesivir for the treatment of severe acute COVID-19 in hospitalized adults and children 12 years of age or older.

Compassionate use access: The manufacturer (Gilead) is transitioning from individual compassionate use requests to an expanded access program for emergency access to the drug for severely ill pts with confirmed COVID-19. New individual compassionate use requests cannot be accepted, with the possible exception of requests for pregnant women and children <18 years of age with confirmed infections and severe manifestations of the disease.

https://rdvcu.gilead.com/

Compassionate use access (NCT04302766): May be available for DoD personnel through treatment IND protocol sponsored by US Army Medical Research and Development Command.

Data from the manufacturer’s compassionate use program: Preliminary data are available for a cohort of 53 adults from multiple sites in the US, Italy, Japan, and
other countries who were hospitalized with severe COVID-19 and received treatment with remdesivir; 40 pts received the full 10-day regimen (200 mg IV on day 1, then 100 mg IV on days 2-10), 10 pts received 5-9 days and 3 pts received less than 5 days of treatment with the drug. At baseline, 30 pts (57%) were receiving mechanical ventilation and 4 (18%) were receiving extracorporeal membrane oxygenation (ECMO). Over a median follow-up of 18 days after first dose, 36 pts (68%) showed clinical improvement based on oxygen-support status and 8 pts (15%) worsened. There were 7 deaths (13%), including 6 pts receiving invasive ventilation. Adverse effects (e.g., increased hepatic enzymes, diarrhea, rash, renal impairment, hypotension) were reported in 32 pts (60%); 12 pts (23%) had serious adverse effects (e.g., multiple organ dysfunction syndrome, septic shock, acute kidney injury, hypotension); 4 pts (8%) discontinued the drug because of adverse effects. Note: Data presented for this small cohort of pts offers only limited information regarding efficacy and safety of remdesivir for treatment of COVID-19. There was no control group and, although supportive therapy could be provided at the discretion of the clinician, it is unclear whether pts at any of the various study sites also received other therapeutic agents being used for treatment of COVID-19. In addition, data were not presented regarding the effects of remdesivir on viral load.

<td>Colchicine</td>
<td>92:16</td>
<td>Exerts broad anti-inflammatory and immunomodulatory effects through multiple mechanisms, including inhibition of NOD-like receptor protein 3 (NLRP3) inflammasome assembly and disruption of cytoskeletal functions through inhibition of microtubule polymerization$^2,3,5,6$. May combat the hyper-inflammatory state of COVID-19 (e.g., cytokine storm) by suppressing pro-inflammatory cytokines and chemokines$^2$. NLRP3 inflammasome activation results in release of interleukins, including IL-1β$^3,5,8,11$. In experimental models of acute respiratory distress syndrome/acute lung injury (ARDS/ALI), the NLRP3 inflammasome had a major role in the development of lung injury$^1,11$. Potential to limit COVID-19-related myocardial damage also has been hypothesized$^2,3$ based on the drug’s mechanisms of action and promising results of ongoing trials.</td>
<td>Minimal anecdotal experience and no clinical trial data reported to date in COVID-19$^4$. <strong>Phase 3, randomized, double-blind, placebo-controlled study</strong> (NCT04322682; COL-CORONA) initiated in adults with COVID-19 and at least one high-risk criterion to evaluate effect of colchicine on mortality, hospitalization rate, and need for mechanical ventilation; study excludes enrollment of currently hospitalized patients; enrollment target is approximately 6000 pts$^5$. Other registered randomized, open-label, parallel-group studies (not yet recruiting) will evaluate effects of colchicine plus standard treatment vs standard treatment alone on various outcome measures (e.g., mortality, markers of myocardial damage, clinical status, need for mechanical ventilation, duration of hospitalization) in adults with COVID-19: NCT04326790, NCT04322565, NCT04328480, NCT04350320, NCT04355143$^1,3$.</td>
<td>Dosage in NCT04322682: Colchicine 0.5 mg orally twice daily for 3 days, then 0.5 mg once daily for 27 days$^1$. Consider possible need for colchicine dosage adjustment;$^7$ manufacturer-recommended dosages for labeled indications depend on patient’s age, renal and hepatic function, and concomitant use of interacting drugs, including protease inhibitors (e.g., lopinavir/ritonavir), other moderate or potent CYP3A4 inhibitors, and P-glycoprotein (P-gp) inhibitors$^5$. Use of colchicine in patients with renal or hepatic impairment receiving P-gp inhibitors or potent CYP3A4 inhibitors is contraindicated$^5$.</td>
<td>Safety and efficacy for treatment of COVID-19 not established</td>
</tr>
</tbody>
</table>

$^a$Dosage based on patient’s age, renal and hepatic function, and concomitant use of interacting drugs, including protease inhibitors (e.g., lopinavir/ritonavir), other moderate or potent CYP3A4 inhibitors, and P-glycoprotein (P-gp) inhibitors.

<tbody>
<tr>
<td>Corticosteroids (general)</td>
<td>68:04 Adrenals</td>
<td>Potent anti-inflammatory and antifibrotic properties; use of corticosteroids may prevent an extended cytokine response and may accelerate resolution of pulmonary and systemic inflammation in pneumonia. Evidence suggests that cytokine storm, a hyperinflammatory state resembling secondary hemophagocytic lymphohistiocytosis (HLH), is a contributing factor in COVID-19-associated mortality. Immunosuppression from corticosteroids has been proposed as a treatment option for such hyperinflammation. May improve dysregulated immune response caused by sepsis (possible complication of infection with COVID-19) and increase BP when low.</td>
<td><strong>Observational studies:</strong> Evidence suggests that corticosteroid use in patients with SARS, MERS, and influenza was associated with no survival benefit and possible harm (e.g., delayed viral clearance, avascular necrosis, psychosis, diabetes). Uncontrolled observational data from the recent COVID-19 outbreak in China suggest a possible treatment benefit of methylprednisolone in COVID-19 patients with acute respiratory distress syndrome (ARDS). (See Methylprednisolone in this Evidence Table.) Pending results of randomized controlled clinical studies specifically evaluating corticosteroids for COVID-19, indirect evidence from studies in patients with community-acquired pneumonia, ARDS, and other viral infections has been used to inform treatment decisions for COVID-19 patients. Systemic corticosteroid therapy has been studied in several randomized controlled studies for the treatment of ARDS; overall evidence is low to moderate in quality and most studies were performed prior to the prelung protection strategy era. In a recent multicenter, unblinded, randomized controlled study (DEXA-ARDS trial), the effects of dexamethasone in conjunction with conventional care were evaluated in hospitalized patients with moderate-to-severe ARDS receiving lung-protective mechanical ventilation.</td>
<td>In general, low to moderate dosages of corticosteroids are recommended in intubated patients with ARDS. Regimens used in China were typically methylprednisolone 40-80 mg IV daily for a course of 3-6 days. Some experts suggest that equivalent dosages of dexamethasone (i.e., 7-15 mg daily, typically 10 mg daily) may have an advantage of producing less fluid retention, since dexamethasone has less mineralocorticoid activity. This dosage of dexamethasone is consistent with those used in the DEXA-ARDS trial. Higher dosages have been suggested for cytokine storm. (See Comments column.)</td>
<td>Data on the use of corticosteroids in COVID-19 are limited. The benefits and risks of corticosteroid therapy should be carefully weighed before use in patients with COVID-19. NIH, CDC, WHO, IDSA, and other experts have issued guidelines for the use of corticosteroids in patients with COVID-19 based on the currently available information. Recommendations are made according to the severity of illness, indications, and underlying medical conditions and should be considered on a case-by-case basis. General recommendations: WHO, CDC, NIH, and IDSA generally recommend against the routine use of corticosteroids for the treatment of COVID-19 unless indicated for another reason (e.g., asthma or COPD exacerbation, refractory septic shock). Non-critical patients: Corticosteroids generally should not be used in the treatment of early or mild disease since the drugs can inhibit immune response, reduce pathogen clearance, and increase viral shedding.</td>
</tr>
</tbody>
</table>
**Drug(s)** | **AHFS Class** | **Rationale** | **Trials or Clinical Experience** | **Dosage** | **Comments**
--- | --- | --- | --- | --- | ---

**Treatment with IV dexamethasone at a dosage of 20 mg once daily on days 1-5, followed by 10 mg once daily on days 6-10 resulted in reduced duration of mechanical ventilation and reduced overall mortality (i.e., 15% increase in 60-day survival) compared with conventional treatment alone.** Based on results of this study, a clinical trial (NCT04325061) has been initiated to specifically evaluate the use of dexamethasone in patients with ARDS due to COVID-19. 21

Other clinical trials have been initiated in various countries to evaluate use of IV corticosteroids (e.g., dexamethasone, hydrocortisone), oral corticosteroids (e.g., prednisone), or inhaled corticosteroids (e.g., budesonide, ciclesonide) for treatment of COVID-19 pneumonia or ARDS, including the following trials registered at clinicaltrials.gov: 22

- NCT04327401
- NCT04344288
- NCT04344730
- NCT04348305
- NCT04355637
- NCT04359511
- NCT04360876
- NCT04381364

(For registered clinical trials evaluating use of methylprednisolone, see Methylprednisolone in this Evidence Table.)

Randomized controlled studies evaluating use of corticosteroids (e.g., hydrocortisone, dexamethasone, methylprednisolone, prednisolone) in septic shock suggest a small, but uncertain mortality reduction. 3, 4

**Critically ill patients:** The Surviving Sepsis Campaign COVID-19 subcommittee (a joint initiative of the Society of Critical Care Medicine and the European Society of Intensive Care Medicine) recommends against the routine use of systemic corticosteroids in mechanically ventilated adults with COVID-19 and respiratory failure (without ARDS). However, these experts generally support a weak recommendation to use low-dose, short-duration systemic corticosteroids in the sickest patients with COVID-19 and ARDS. 12

NIH also recommends against the routine use of systemic corticosteroids for the treatment of mechanically ventilated COVID-19 patients without ARDS. However, the NIH panel states that there is insufficient evidence for or against the use of systemic corticosteroids in mechanically ventilated patients with COVID-19 and ARDS. 24

IDSA suggests against using corticosteroids in hospitalized patients with COVID-19 pneumonia; however, in those with ARDS due to COVID-19, systemic corticosteroids may be used in the context of a clinical trial. 25

**Cytokine storm:** There is no well-established or evidence-based treatment for cytokine storm in patients with COVID-19. 8 However, some experts suggest that use of more potent immunosuppression with corticosteroids may be beneficial in such patients. 8 These experts suggest higher dosages of corticosteroids (e.g., IV methylprednisolone 60-125 mg every 6 hours for up to 3 days) followed by tapering of the dose when inflammatory markers (e.g., C-reactive protein levels) begin to decrease. 8 The decision to use corticosteroids in patients with early signs of cytokine storm should be balanced with the known adverse effects. 24

<td></td>
<td></td>
<td></td>
<td><strong>Septic shock:</strong> The effect of corticosteroids in COVID-19 patients with sepsis or septic shock may be different than the effects seen in those with ARDS. The Surviving Sepsis Campaign and NIH suggest the use of low-dose corticosteroid therapy (e.g., hydrocortisone 200 mg daily as an IV infusion or intermittent doses) over no corticosteroid therapy in adults with COVID-19 and refractory shock. Clinicians considering corticosteroids for such patients with COVID-19 should balance the potential small reduction in mortality with potential effects of prolonged coronavirus shedding. If corticosteroids are prescribed, monitor and treat adverse effects including hyperglycemia, hypernatremia, and hypokalemia. Patients receiving corticosteroid therapy for chronic conditions: NIH states that oral corticosteroids used for the treatment of an underlying condition prior to COVID-19 infection (e.g., primary or secondary adrenal insufficiency, rheumatologic diseases) should not be discontinued. Supplemental or stress dosages of corticosteroids may be indicated on an individual basis in patients with such conditions. The guidelines also recommend that inhaled corticosteroids used daily for the management of asthma and COPD to control airway inflammation should not be discontinued in patients with COVID-19. Rheumatology experts, including members of the American College of Rheumatology COVID-19 Clinical Guidance Task Force, state that abrupt discontinuance of corticosteroid therapy in patients with rheumatologic diseases should be avoided regardless of COVID-19 exposure or infection status. These experts also state that if indicated, corticosteroids should be used at the lowest effective dosage to control manifestations, but also acknowledge that higher dosages may be necessary in the context of severe, vital organ-threatening...</td>
</tr>
</tbody>
</table>
Although patients with COVID-19 may require treatment with corticosteroids for inflammatory processes associated with this illness, especially for patients with severe disease, guidelines for patients with adrenal insufficiency are needed. Studies of patients with primary or secondary adrenal insufficiency who have been exposed to COVID-19 have shown that up to 20% of patients develop symptoms following infection. Rheumatologic disease even following COVID-19 exposure.

Endocrinology experts state that patients with primary or secondary adrenal insufficiency who are receiving prolonged corticosteroid therapy should follow usual steroid “sick day rules” since these individuals may not be able to mount a normal stress response in the event of COVID-19 infection. If such individuals develop symptoms such as fever and a dry continuous cough, they should immediately double their daily oral corticosteroid dosage and continue with this regimen until the fever subsides. These guidelines also apply to patients who are receiving prolonged therapy (> 3 months) with corticosteroids for underlying inflammatory conditions, including asthma, allergy, and rheumatoid arthritis. In such patients whose condition worsens or in those experiencing vomiting or diarrhea, treatment with parenteral corticosteroids may be necessary. Administration of physiologic stress doses of corticosteroids (e.g., IV hydrocortisone 50-100 mg 3 times daily) and not pharmacologic doses should be considered in all cases to avoid potentially fatal adrenal failure.

Additional study is needed to determine the optimum corticosteroid stress dosage regimens in patients with COVID-19. There is some evidence suggesting that continuous IV infusion of hydrocortisone (following an initial IV bolus dose) may provide more stable circulating cortisol concentrations in patients with adrenal insufficiency and reduce the potentially harmful effects of peak and trough concentrations of cortisol on the immune system.

Pregnancy considerations: For pregnant women with COVID-19, NIH guidelines state that the antenatal use of corticosteroids that cross the placenta (i.e., betamethasone, dexamethasone) is generally reserved for when administration is required for fetal benefit. Other

</table>
| Epoprostenol (inhaled)              | 48:48      | Selective pulmonary vasodilator; may be useful in the adjunctive treatment of acute respiratory distress syndrome (ARDS), a potential complication of COVID-19<sup>1,9</sup>  
Inhaled epoprostenol has been suggested as an alternative to inhaled nitric oxide due to its similar efficacy, lower potential for systemic adverse effects, lower cost, and ease of delivery<sup>1,2,9</sup>                                                                 | No studies evaluating use specifically in COVID-19 patients<sup>10</sup>  
Experience in patients with ARDS indicates that inhaled epoprostenol can substantially reduce mean pulmonary artery pressure and improve oxygenation in such patients; however, data demonstrating clinical benefit are lacking<sup>3,6-9</sup> | Various dosages of inhaled epoprostenol have been used in ARDS studies<sup>2,9</sup>  
Dosages up to 50 ng/kg per minute have been used (titrated to response)<sup>1,4,6,9</sup>  
To provide a clinically important increase in PaO<sub>2</sub> and reduction in pulmonary artery pressure, data from these studies suggest that the most effective and safe dosage appears to be 20-30 ng/kg per minute in adults and 30 ng/kg per minute in pediatric patients<sup>9</sup> | Additional studies are needed to evaluate the potential role of inhaled epoprostenol in the treatment of ARDS<sup>6,9</sup>  
The Surviving Sepsis Campaign states that due to the lack of adequately powered randomized controlled studies, a recommendation cannot be made for or against use of inhaled prostacyclins in COVID-19 patients with severe ARDS<sup>10</sup> |
| Methylprednisolone (DEPO-Medrol®, SOLU-Medrol<sup>®</sup>) | 68:04      | Potent anti-inflammatory and antifibrotic properties; use of corticosteroids may prevent an extended cytokine response and may accelerate resolution of pulmonary and systemic inflammation in pneumonia<sup>3,9</sup>  
(See Corticosteroids in this Evidence Table.)                                                                                                                     | Retrospective, observational, single-center study: In 201 patients with confirmed COVID-19 pneumonia who developed ARDS, methylprednisolone appeared to reduce the risk of death<sup>8</sup>  
Among patients with ARDS, of those who received methylprednisolone treatment, 23 of 50 (46%) patients died, while of those who did not receive methylprednisolone, 21 of 34 (61.8%) died<sup>6</sup> | Dosage used in the retrospective study (Wu et al) not provided<sup>6</sup>  
Dosage used in the retrospective study (Wang et al) was 1-2 mg/kg daily IV for 5-7 days<sup>11</sup>  
Dosage used in the randomized, controlled study (NCT04244591) was 40 mg IV every 12 hours for 5 days<sup>23</sup> | Findings from observational studies suggest that for patients with COVID-19 pneumonia who progress to ARDS, methylprednisolone treatment may be beneficial. However, results should be interpreted with caution because of potential bias (drug used in sickest patients) and small sample size. Confirmation from randomized controlled studies is needed.<sup>6,13</sup>  
(See Corticosteroids in this Evidence Table for general recommendations on corticosteroid use in patients with COVID-19.) |

### Drug(s) | AHFS Class | Rationale | Trials or Clinical Experience | Dosage | Comments
--- | --- | --- | --- | --- | ---
Nitric oxide (inhaled) | 48:48 Vasodilating Agent | Selective pulmonary vasodilator; may be useful in the adjunctive treatment of acute respiratory distress syndrome (ARDS), a potential complication of COVID-19 | Death occurred in 3 patients during hospitalization; 2 of these patients received methylprednisolone. 

**Open-label, multicenter, randomized controlled study** (NCT04244591) was recently completed in China that compared use of methylprednisolone in conjunction with standard care in patients with confirmed COVID-19 infection that progressed to acute respiratory failure; results have not yet been posted.

Multiple clinical trials have been initiated in various countries to evaluate use of methylprednisolone for treatment of COVID-19 pneumonia or severe acute respiratory syndrome, including the following trials registered at clinicaltrials.gov: NCT03852537, NCT04263402, NCT04273321, NCT04323592, NCT04329650, NCT04343729, NCT04374071.

A non-randomized pilot study registered at clinicaltrials.gov (NCT04355247) has been initiated to evaluate use of methylprednisolone for the prevention of COVID-19 cytokine storm and progression to respiratory failure.

No studies evaluating use specifically in COVID-19 patients.

In a small pilot study (Chen et al.) conducted in China during the 2003 SARS-CoV outbreak, treatment with inhaled nitric oxide in ICU patients with SARS reversed pulmonary hypertension, improved severe hypoxia, and shortened the duration of ventilatory support.

Randomized controlled studies of inhaled nitric oxide in ARDS patients generally demonstrated modest improvements in oxygenation, but no effect on mortality and possible harm (e.g., renal impairment).

In the Chen et al. study in severe SARS patients, inhaled nitric oxide therapy was given for ≥3 days (30 ppm on day 1, followed by 20 and 10 ppm on days 2 and 3, respectively, then weaned on day 4; therapy was resumed at 10 ppm if deteriorating oxygenation occurred).

Phase 2 clinical trial protocol (NCT04306393) for treatment of mechanically ventilated COVID-19 patients: 80 ppm for the first 48 hours, followed by 40 ppm and then subsequently wean.

Therapeutic guidelines for the treatment of ARDS state that inhaled nitric oxide may be considered in patients with severe hypoxemia not responsive to conventional ventilation strategies; however, routine use not recommended.

The Surviving Sepsis Campaign suggests a trial of inhaled pulmonary vasodilator therapy as rescue therapy in mechanically ventilated adults with COVID-19, severe ARDS, and hypoxemia despite optimized ventilation and other rescue strategies; if rapid improvement in oxygenation is not observed, treatment should be tapered off.

</table>
| ACE Inhibitors, Angiotensin II Receptor Blockers (ARBs) | 24:32 Renin-Angiotensin-Aldosterone System Inhibitor (ACEIs) | **Hypothetical harm:** Human pathogenic coronaviruses bind to their target cells through angiotensin-converting enzyme 2 (ACE2).\(^1,4,7\) Expression of ACE2 may be increased in patients treated with ACE inhibitors or ARBs.\(^1,4,8\) Increased expression of ACE2 may potentially facilitate COVID-19 infections.\(^1\) 
**Hypothetical benefit:** ACE inhibitors or ARBs may have a protective effect against lung damage or may have paradoxical effect in terms of virus binding.\(^1,2,6\) | Data are lacking; no evidence of harm or benefit with regards to COVID-19 infection.\(^2,3\) Clinical trial underway: Initiation of losartan in adult patients with COVID-19 requiring hospitalization; primary outcome measure: sequential organ failure assessment (SOFA) respiratory score. (NCT04312009)\(^9\) |  | American Heart Association (AHA), American College of Cardiology (ACC), Heart Failure Society of America (HFSA), European Society of Cardiology (ESC) recommend to continue treatment with renin-angiotensin-alderosterone system (RAAS) antagonists in those patients who are currently prescribed such agents.\(^2,3\) NIH COVID-19 Treatment Guidelines Panel states patients who are receiving an ACE inhibitor or ARB for cardiovascular disease (or other indications) should continue receiving these drugs; recommends against use of ACE inhibitors or ARBs for the treatment of COVID-19 except in the context of a clinical trial.\(^9\) 
Patients with cardiovascular disease are at an increased risk of serious COVID-19 infections.\(^3,8\) 
Abrupt withdrawal of RAAS inhibitors in high-risk patients (e.g., heart failure patients, patients with prior myocardial infarction) may lead to clinical instability and adverse health outcomes.\(^8\) |
| Anticoagulants (low molecular weight heparin [LMWH], unfractionated heparin [UFH]) | 20:12.04.16 Heparins | Patients with COVID-19, particularly those with severe disease, may develop a hypercoagulable state, which has been associated with poor outcomes (e.g., progressive respiratory failure, acute respiratory distress syndrome [ARDS], death).\(^1,6,14,16,26,29\) 
Coagulation abnormalities observed include prothrombotic disseminated intravascular coagulation (DIC), VTE, elevated D-dimer levels, high fibrinogen levels, and microvascular and macrovascular thrombosis.\(^1,6,8,11,16,28\) 
True incidence of these complications not known, | Limited data from a retrospective study in China showed reduced mortality in COVID-19 patients with severe sepsis-induced coagulopathy or markedly elevated D-dimer levels (>6 x ULN) who received prophylactic anticoagulation (LMWH or UFH).\(^4,19\) 
Several prospective, randomized open-label studies (NCT04373707, NCT04372589, NCT04345848) are being conducted to evaluate prophylactic- and therapeutic-dose anticoagulation in hospitalized adults with severe COVID-19 infection.\(^12\) |  | Additional study is needed to understand the anticoagulant needs of COVID-19 patients.\(^6,11,27,28,29\) 
Several organizations have published interim guidance for the management of COVID-19-associated coagulopathy.\(^4,5,9,25,27,28,30\) 
The NIH COVID-19 Treatment Guideline Panel states that all hospitalized adults with COVID-19 should receive VTE prophylaxis according to the usual standard of care in patients without COVID-19 unless contraindicated.\(^28\) 
The International Society for Thrombosis and Haemostasis, American College of Cardiology, and American Society of Hematology recommend that all hospitalized COVID-19 patients receive prophylactic-dose LMWH unless contraindicated. |
### Drug(s) | AHFS Class | Rationale | Trials or Clinical Experience | Dosage<sup>a</sup> | Comments
---|---|---|---|---|---
but have varied in patients with different severities of disease.<sup>28</sup>

Pathogenesis of COVID-19-related coagulopathy not completely known, but may be related to inflammatory response to viral infection.<sup>16, 17, 27-29</sup>

Anticoagulant therapy may reduce the risk of thrombotic complications and improve clinical outcomes.<sup>2, 4, 5, 14, 25, 27</sup>

An additional benefit of heparins is their anti-inflammatory effects.<sup>5, 7, 8, 17</sup>

e.g., active bleeding, severe thrombocytopenia, fibrinogen <0.5 g/L).<sup>4, 5, 30</sup> Abnormal PT or aPTT is not a contraindication for prophylaxis.<sup>4, 5</sup>

WHO recommends pharmacologic prophylaxis with LMWH (preferred) or UFH (5000 units sub-Q twice daily) in adults and adolescents with COVID-19 who do not have contraindications.<sup>25</sup>

LMWH or UFH may be preferred over oral anticoagulants in critically ill hospitalized patients with COVID-19 because of their shorter half-lives, ability to be administered parenterally, and fewer drug-drug interactions.<sup>28</sup> Practical concerns (e.g., need for frequent monitoring, convenience of administration, risk of medical staff exposure) may influence institutional choice of anticoagulant.<sup>8, 9, 14, 20, 27</sup>

Because of the severity of coagulopathy in critically ill COVID-19 patients and reports of high rates of VTE despite standard prophylaxis, some clinicians have suggested the use of higher prophylactic doses or even therapeutic doses of anticoagulants to prevent thrombotic events in patients with COVID-19; however, high-quality prospective studies are needed to evaluate these approaches.<sup>11, 14, 17, 20-24, 26, 27, 28, 30</sup> Pending additional data, it is recommended that use of higher-intensity nonstandard VTE prophylaxis or therapeutic anticoagulation should ideally be done in the context of a clinical trial.<sup>28, 30</sup>

The NIH COVID-19 Treatment Panel and other experts state that the current data are insufficient to recommend for or against the use of therapeutic anticoagulation in COVID-19 patients in the absence of confirmed or suspected thrombosis.<sup>4, 28, 30</sup> The efficacy of intermediate or full therapeutic anticoagulation for critically ill COVID-19 patients without documented VTE is currently being evaluated.<sup>4, 12</sup> Patients who are...

antibody testing, and minimum titers of SARS-CoV-2 antibody in convalescent plasma that may be associated with clinical benefits in pts with COVID-19 not determined. 1,5 

Logistics of obtaining, processing, storing, and distributing COVID-19 convalescent plasma evolving. 1,5,11,14,15 FDA does not collect COVID-19 convalescent plasma and does not provide such plasma; healthcare providers and acute care facilities obtain COVID-19 convalescent plasma from FDA-registered establishments. 51

Potential risks associated with COVID-19 convalescent plasma therapy (e.g., inadvertent transmission of other infectious agents, allergic reactions, thrombotic complications, transfusion-associated circulatory overload, transfusion-related acute lung injury [TRALI], antibody-dependent enhancement of infection) and steps to mitigate such risks not fully determined and require further evaluation. 1,5,9,23,24,25

FDA issued a guidance for industry to provide recommendations to healthcare providers and investigators regarding administration and study of investigational COVID-19 convalescent plasma. This guidance document includes recommendations regarding pathways for access to COVID-19 convalescent plasma, patient eligibility to receive such plasma, collection of such plasma (including donor eligibility and qualifications), product labeling, and recordkeeping. 52

There are no convalescent blood products currently licensed by the FDA. 25 COVID-19 convalescent plasma is regulated as an investigational product. 51 FDA states that there are 3 available pathways for administering or studying the use of such plasma:

1) **Clinical Trials:** Requests to study use of COVID-19 convalescent plasma. 11

<tr>
<td>Multiple clinical trials have been initiated in the US and other countries to evaluate use of COVID-19 convalescent plasma in various settings (e.g., postexposure prophylaxis, treatment of different stages of the disease). Some of the trials that are currently recruiting are listed below. For additional trials, see clinicaltrials.gov:</td>
<td>should be submitted to FDA under the traditional investigational new drug (IND) regulatory pathway.</td>
<td>11</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

2. **Expanded Access IND:** For patients with serious or immediately life-threatening COVID-19 who are not eligible or are unable to participate in randomized clinical trials, an expanded access IND can be used. A National Expanded Access Treatment Protocol has been established to facilitate access through participation of acute care facilities under an IND that is already in place. Information on a protocol that is currently in place is available at [https://www.uscovidplasma.org](https://www.uscovidplasma.org). 11

3. **Single Patient Emergency IND (eIND):** Licensed physicians seeking to administer COVID-19 convalescent plasma to individual patients with serious or life-threatening disease may request an eIND from the FDA. Consult the FDA guidance document for specific information on applying for an eIND. 11

**Donor eligibility:** FDA guidance suggests that COVID-19 convalescent plasma be collected from individuals with laboratory-confirmed evidence of COVID-19 infection and complete resolution of symptoms for at least 14 days before donation (a negative result for COVID-19 by a diagnostic test is not necessary to qualify the donor). 11

**Antibody titers in donor plasma:** If measurement of antibody titers is available, FDA recommends a neutralizing antibody titer of at least 1:160 (a titer of 1:80 may be considered acceptable if an alternative matched unit of plasma is not available). 11

**Patient eligibility:** For healthcare providers seeking an eIND for the treatment of patients with severe or life-threatening disease, consideration should be given to following the patient eligibility criteria used in the National Expanded Access Treatment Protocol [https://www.uscovidplasma.org](https://www.uscovidplasma.org). 11

<td>Famotidine</td>
<td>56:28.12</td>
<td>Computer-aided, structure-based, virtual screening of libraries of compounds against SARS-CoV-2 proteins suggested potential for famotidine to interact with viral proteases involved in coronavirus replication$^1$.</td>
<td>Currently no known published prospective clinical trial evidence supporting efficacy or safety for treatment of COVID-19. Randomized, double-blind, historical-controlled, comparative trial (NCT04370262) initiated in New York in hospitalized adults with moderate to severe COVID-19; trial includes 2 active treatment groups (high-dose IV famotidine with oral hydroxychloroquine, IV placebo with oral hydroxychloroquine) and a historical control group receiving neither of these drugs (patients treated during early stages of the COVID-19 pandemic in New York); targeted enrollment is 600 patients in each active treatment group; 2 interim analyses planned$^5$.</td>
<td>Dosage in NCT04370262: Famotidine is being given IV in 120-mg doses (proposed total daily dosage of 360 mg) for maximum of 14 days or until hospital discharge, whichever comes first$^5$. Proposed daily dosage in NCT04370262 is 9 times the usual manufacturer-recommended IV adult dosage; the study excludes patients with creatinine clearance (C\text{\text{cr}}) ≤50 mL/minute, including dialysis patients; renally impaired patients may be at increased risk of adverse CNS effects since drug half-life is closely related to C\text{\text{cr}}$^6$.</td>
<td>Safety and efficacy for treatment of COVID-19 not established.</td>
</tr>
</tbody>
</table>

Anecdotal observations:
Observations based on retrospective medical record review indicated that many Chinese COVID-19 survivors had received famotidine for chronic heartburn; mortality rate appeared to be lower in hospitalized COVID-19 patients receiving famotidine than in patients not receiving the drug (14 vs 27%); observations did not control for possible confounding (e.g., socioeconomic factors$^5$. Retrospective matched cohort study of COVID-19 patients initially hospitalized in non-ICU setting at a single New York medical center indicated that the risk for the composite outcome of death or intubation was reduced (mainly due to difference in mortality) in patients who received famotidine within

According to the protocol, **severe disease** is defined as one or more of the following: shortness of breath, respiratory frequency 30/minute or greater, blood oxygen saturation 93% or lower, PaO$_2$/FiO$_2$ ratio less than 300, lung infiltrates greater than 50% within 24-48 hours, and **life-threatening disease** is defined as one or more of the following: respiratory failure, septic shock, multiple organ dysfunction or failure.$^{11}$

<tr>
<td>HMG-CoA Reductase Inhibitors (statins)</td>
<td>24:06 Antilipemic Agents</td>
<td>In addition to lipid-lowering effects, statins have anti-inflammatory and immunomodulatory effects which may prevent acute lung injury. Statins affect ACE2 as part of their function in reducing endothelial dysfunction.</td>
<td>Data are lacking on the use of statins in patients with COVID-19. Preliminary findings have shown mixed results with other respiratory illnesses; some observational studies suggest statin therapy is associated with a reduction in various cardiovascular outcomes and possibly mortality in patients hospitalized with influenza and/or pneumonia. Clinical trials are evaluating the effectiveness of statins (with and without other potential treatment agents) for the treatment of COVID-19. (NCT04348695, NCT04333407)</td>
<td>NIH COVID-19 Treatment Guidelines Panel states patients who are receiving a statin for the treatment or prevention of cardiovascular disease should continue statin therapy; recommends against use of statins for the treatment of COVID-19 except in the context of a clinical trial. Patients with cardiovascular disease are at an increased risk of serious COVID-19 infections. In patients with active COVID-19 who may develop severe rhabdomyolysis, it may be advisable to withhold statin therapy for a short period of time. Most statins are substrates for the CYP450 system; potential for drug interactions. Clinicians should ensure that their high-risk primary prevention (for ASCVD) patients are on guideline-directed statin therapy.</td>
<td></td>
</tr>
<tr>
<td>Immune Globulin</td>
<td>80:04 Immune Globulin</td>
<td>Commericially available immune globulin (IGIV, IVIG, γ-globulin) is derived from pooled plasma and contains many antibodies normally present in adult human blood; used for replacement therapy in patients with primary humoral immunodeficiency who are unable to produce sufficient IgG antibodies and also used to provide passive immunity to certain viral infections in other individuals. Investigational SARS-CoV-2 immune globulin is a concentrated immune globulin preparation containing specific antibody derived from the plasma of individuals.</td>
<td>SARS Experience: IGIV has been used in the treatment of SARS. Benefits were unclear because of patient comorbidities, differences in stage of illness, and effect of other treatments; IGIV may have contributed to hypercoagulable state and thrombotic complications in some patients. COVID-19 case reports in China (Cao et al): Treatment with IGIV at the early stage of clinical deterioration was reported to provide some clinical benefit in 3 adults with severe COVID-19; 2 patients also received antivirals and 1 patient also received short-term steroid treatment. Patients were afebrile within 1-2 days and breathing difficulties gradually improved within 3-5 days of IGIV administration. COVID-19 clinical experience in China: IGIV has been used as an adjunct in the treatment of COVID-19 and has been mentioned in Chinese guidelines as a possible role of commercially available immune globulin (IGIV, IVIG, γ-globulin) and investigational SARS-CoV-2 immune globulin in the treatment of COVID-19 unclear.</td>
<td>IGIV dosage of 0.3-0.5 g/kg daily for 5 days has been used in some patients with COVID-19. The Surviving Sepsis Campaign COVID-19 subcommittee suggests that IGIV not be used routinely in critically ill adults with COVID-19 because efficacy data not available, currently available IGIV preparations may not contain antibodies against SARS-CoV-2, and IGIV can be associated with increased risk of severe adverse effects (e.g., anaphylaxis, aseptic meningitis, renal failure, thromboembolism, hemolytic reactions, transfusion-related lung injury). The NIH COVID-19 Treatment Guideline Panel recommends against the use of commercially available IGIV (i.e., non-commercially available IGIV).</td>

patients who took ibuprofen and suffered severe outcomes with COVID-19. Official case reports are lacking.

On 3/19/20, FDA issued a statement that it is not aware of scientific evidence connecting the use of NSAIDs, such as ibuprofen, with worsening COVID-19 symptoms. FDA stated that it is investigating this issue further and will communicate publicly when more information is available. FDA also noted that all prescription NSAID labels warn that by reducing inflammation, and possibly fever, these drugs may diminish the utility of diagnostic signs in detecting infections. [https://www.fda.gov/drugs/drug-safety-and-availability/fda-advises-patients-use-non-steroidal-anti-inflammatory-drugs-nsaids-covid-19](https://www.fda.gov/drugs/drug-safety-and-availability/fda-advises-patients-use-non-steroidal-anti-inflammatory-drugs-nsaids-covid-19)

Therefore, currently no compelling evidence to support an association between ibuprofen and negative outcomes in patients with COVID-19. However, some experts have recommended preferentially using acetaminophen for treatment of fever.²,³,⁴

NIH COVID-19 Treatment Guidelines Panel states that patients who are receiving NSAIDs for other conditions should continue receiving the drugs; states antipyretic strategy (e.g., use of acetaminophen or NSAIDs) should be no different between patients with or without COVID-19.⁵

The Surviving Sepsis Campaign COVID-19 guidelines state that until more evidence is available, use of acetaminophen over no treatment for fever control is suggested (weak recommendation).²

<td>Tissue Plasminogen Activator (t-PA; alteplase)</td>
<td>20:12.20 Thrombolytic agents</td>
<td>A consistent finding in patients with severe COVID-19 is a hypercoagulable state, which may contribute to their risk of poor outcomes (e.g., progressive respiratory failure, acute respiratory distress syndrome [ARDS], death).</td>
<td>Results of a small phase 1 study conducted in 2001 suggest possible benefit of plasminogen activators for the treatment of ARDS. In this study, 20 patients with ARDS secondary to trauma and/or sepsis who failed to respond to standard ventilator therapy and were not expected to survive were treated with urokinase or streptokinase; such therapy improved PaO&lt;sub&gt;2&lt;/sub&gt; and also appeared to improve survival. A registered open-label randomized trial (NCT04357730) will evaluate systemic fibrinolytic therapy with t-PA versus standard care in mechanically ventilated COVID-19 patients with severe respiratory failure. A registered open-label nonrandomized pilot study (NCT04356833) will evaluate an inhaled formulation of t-PA (via nebulization) in patients with ARDS due to COVID-19, including 2% 9, 14 Patients with ARDS (regardless of the cause), pathologic findings include fibrin deposition in the alveoli and formation of microthrombi in the pulmonary vasculature. Treatment with t-PA may restore microvascular patency and limit progression of ARDS in patients with COVID-19. Results from the first few cases reported an initial, but transient improvement in oxygenation (P/F) ratio. However, there are currently no clinical trial data to inform this practice and a lack of clinical experience with the use of fibrinolytic agents in ARDS patients in general. Several institutions (Beth Israel Deaconess, University of Colorado Anschultz Medical Campus, Denver Health) are currently testing the use of t-PA as salvage therapy in patients with severe COVID-19 under the FDA compassionate use program. Preliminary findings suggest possible benefit of plasminogen activators for the treatment of ARDS. The American Society of Hematology states that treatment of the underlying pathology is paramount in COVID-19 patients with coagulopathies; supportive care should be individualized and standard risk factors for bleeding should be considered.</td>
