Assessment of Evidence for COVID-19-Related Treatments: Updated 10/1/2020

The information contained in this evidence table is emerging and rapidly evolving because of ongoing research and is subject to the professional judgment and interpretation of the practitioner due to the uniqueness of each medical facility’s approach to the care of patients with COVID-19 and the needs of individual patients. ASHP provides this evidence table to help practitioners better understand current approaches related to treatment and care. ASHP has made reasonable efforts to ensure the accuracy and appropriateness of the information presented. However, any reader of this information is advised ASHP is not responsible for the continued currency of the information, for any errors or omissions, and/or for any consequences arising from the use of the information in the evidence table in any and all practice settings. Any reader of this document is cautioned that ASHP makes no representation, guarantee, or warranty, express or implied, as to the accuracy and appropriateness of the information contained in this evidence table and will bear no responsibility or liability for the results or consequences of its use.

ASHP’s patient medication information is available at [http://www.safemedication.com/](http://www.safemedication.com/). Visit our website for the latest information on current drug shortages.

Selected entries were updated 10/1/20; these can be identified by the date that appears in the Drug(s) column. Within updated entries, select revisions that include the most important new information (e.g., new clinical trial data, new or revised guidance) are marked by **.

### TABLE OF CONTENTS

#### ANTIVIRAL AGENTS
- **UPDATED** BALOXAVIR
- **UPDATED** CHLOROQUINE PHOSPHATE
- **UPDATED** FAVIPIRAVIR (Avigan®, Avifavir®, Favilavir)
- **UPDATED** HIV PROTEASE INHIBITORS (e.g., LPV/RTV, Kaletra®)
- **UPDATED** HYDROXYCHLOROQUINE (Plaquenil®)
- **UPDATED** NEURAMINIDASE INHIBITORS (e.g., oseltamivir)
- **UPDATED** REMDESIVIR (Veklury®)
- **UPDATED** UMIFENOVIR (Arbidol®)

#### SUPPORTING AGENTS
- **UPDATED** ANAKINRA (Kineret®)
- **UPDATED** ASCORBIC ACID
- **UPDATED** AZITHROMYCIN
- **UPDATED** BARICITINIB (Olumiant®)
- **UPDATED** COLCHICINE
- **UPDATED** CORTICOSTEROIDS (systemic)
- **UPDATED** CORTICOSTEROIDS (inhaled)
- **UPDATED** INHALED PROSTACYCLINS
- **UPDATED** INTERFERONS
- **UPDATED** NITRIC OXIDE (inhaled)
- **UPDATED** RUXOLITINIB (Jakafi®)
- **UPDATED** SARILUMAB (Kevzara®)
- **UPDATED** SILTUXIMAB (Sylvant®)
- **UPDATED** SIROLIMUS (Rapamune®)
- **UPDATED** TOCILIZUMAB (Actemra®)
- **UPDATED** VITAMIN D
- **UPDATED** ZINC

#### OTHER
- **UPDATED** ACE INHIBITORS, ANGIOTENSIN II RECEPTOR BLOCKERS (ARBs)
- **UPDATED** ANTICOAGULANTS
- **UPDATED** COVID-19 CONVALESCENT PLASMA
- **UPDATED** FAMOTIDINE
- **UPDATED** HMG-CoA REDUCTASE INHIBITORS (statins)
- **UPDATED** IMMUNE GLOBULIN
- **UPDATED** IVERMECTIN
- **UPDATED** NEBULIZED DRUGS
- **UPDATED** NICLOSAMIDE
- **UPDATED** NITAZOXANIDE
- **UPDATED** NONSTEROIDAL ANTI-INFLAMMATORY AGENTS (NSAIDs)
- **UPDATED** THROMBOLYTIC AGENTS (t-PA [alteplase], tenecteplase)
### ANTIVIRAL AGENTS

<td>Baloxavir</td>
<td>8:18.92</td>
<td>Antiviral</td>
<td><strong>Only very limited data available</strong> regarding use of baloxavir for treatment of COVID-19&lt;br&gt;Exploratory, open-label, randomized controlled study at a single center in China (ChiCTR2000029544): 29 adults hospitalized with COVID-19 receiving antiviral treatment with lopinavir/ritonavir, darunavir/cobicistat, or umifenovir (Arbidol®), in combination with inhaled interferon-α, were randomized to treatment with baloxavir marboxil (80 mg orally on day 1 and on day 4, and 80 mg orally on day 7 as needed) (n=10), favipiravir (1600 or 2200 mg orally on day 1, followed by 600 mg three times daily for up to 14 days) (n=9), or control (standard antiviral treatment) (n=10). Percentage of pts with viral conversion (2 consecutive tests with undetectable viral RNA results) after 14 days of treatment was 70, 77, and 100% in the baloxavir, favipiravir, and control groups, respectively, with median time to clinical improvement of 14, 14, and 15 days, respectively. ¹&lt;br&gt;There are no clinical trials registered at clinicaltrials.gov to evaluate baloxavir for treatment of COVID-19.</td>
<td>A baloxavir marboxil dosage of 80 mg on day 1 and on day 4, and another dose of 80 mg on day 7 (as needed; not to exceed 3 total doses) was used in one open-label COVID-19 study in adults in China. ²</td>
<td>No data support use of baloxavir in the treatment of COVID-19</td>

<tr>
<td>Known pharmacokinetics and toxicity profile based on use for other indications 13, 17</td>
<td></td>
<td></td>
<td><strong>Double-blind, randomized, phase 2b study in Brazil</strong> (Borba et al; NCT04323527): Efficacy and safety of two different chloroquine dosages were evaluated for adjunctive therapy in hospitalized adults with severe COVID-19. According to the initial study protocol, pts were randomized 1:1 to receive high-dose chloroquine (600 mg twice daily for 10 days) or lower-dose chloroquine (450 mg twice daily on day 1, then 450 mg once daily on days 2-5); all pts also received azithromycin and ceftriaxone and some also received oseltamivir. An unplanned interim analysis was performed and the high-dose arm of the study was halted because of toxicity concerns, particularly QTc prolongation and ventricular tachycardia, and because more deaths were reported in this arm. Analysis of data available for the first 81 enrolled pts indicated that, by day 13, 16/41 pts (39%) treated with the high-dose regimen had died vs 6/40 (15%) treated with the lower-dose regimen. QTc &gt;500 msec occurred more frequently in the high-dose group (18.9%) than in the lower-dose group (11.1%). <strong>Note:</strong> The high-dose arm included more pts prone to cardiac complications than the lower-dose arm. Data at the time of the interim analysis were insufficient to evaluate efficacy. 37</td>

**Updated 10/1/20**

In vitro evidence of activity against SARS-CoV-2 in infected Vero E6 cells reported with high concentrations of the drug 1, 5, 16

Licensed in Japan and China for treatment of influenza 7, 4, 6

**Open-label, prospective, randomized, multicenter study** in 236 adults with COVID-19 pneumonia in China (ChiCTR2000030254): Favipiravir (1600 mg orally twice daily on day 1, then 600 mg orally twice daily thereafter for 7–10 days) was associated with greater clinical recovery rate at 7 days (61 vs 52%) compared with the control group treated with umifenovir (Arbidol®; 200 mg 3 times daily for 7–10 days). Stratified by disease severity, clinical recovery rate at day 7 in pts with moderate COVID-19 pneumonia was 71% in the favipiravir group vs 56% in the umifenovir group; clinical recovery rate in those with severe to critical COVID-19 pneumonia was 6% vs 0%, respectively. Twice as many pts in the favipiravir group had severe to critical disease compared with the group receiving umifenovir. 6

**Open-label, prospective, randomized, multicenter study** in 60 hospitalized adults with moderate COVID-19 pneumonia in Russia (NCT04434248): Favipiravir (1600 mg orally twice daily on day 1, then 600 mg twice daily on days 2–14 or 1800 mg twice daily on day 1, then 800 mg twice daily on days 2–14) was associated with higher rate of viral clearance at 10 days (92.5 vs 80%) compared with the control group receiving the standard of care. Favipiravir also was associated with decreased median time to normalization of body temperature (2 vs 4 days) and higher improvement rate on chest CT imaging on day 15 (90 vs 80%)

Given the lack of pharmacokinetic and safety data for the high favipiravir dosages proposed for treatment of COVID-19, the drug should be used with caution at such dosages. 12, 20 Favipiravir is associated with QT prolongation. 21 Some have suggested close cardiac and hepatic monitoring during treatment, as well as monitoring of plasma and tissue concentrations of the drug and, if possible, the active metabolite. 19, 20, 21 Some data suggest that favipiravir exposure may be greater in Asian populations. 17, 19

Early embryonic deaths and teratogenicity observed in animal studies. Favipiravir is contraindicated in women with known or suspected pregnancy and precautions should be taken to avoid pregnancy during treatment with the drug. 14

If favipiravir is used in pts receiving acetaminophen, the maximum recommended daily dosage of acetaminophen is 3 g. 17, 18

<td>Lopinavir (LPV)</td>
<td>8:18.08.08</td>
<td>Some evidence of in vitro activity against SARS-CoV-2 in Vero E6 cells; evidence of in vitro activity against SARS-CoV-1 and MERS-CoV; evidence of benefit in animal studies for treatment of MERS-CoV 4,7,9,11</td>
<td>Lopinavir and Ritonavir (LPV/RTV; Kaletra®) randomized, open-label trial in China [Cao et al] in hospitalized adults with severe COVID-19 compared LPV/RTV in conjunction with standard care (99 pts) vs standard care alone (100 pts). Primary end point was time to clinical improvement (time from randomization to improvement of two points on a seven-category ordinal scale or hospital discharge, whichever came first). In ITT population, time to clinical improvement was not shorter with LPV/RTV compared with standard care (median time to clinical improvement 16 days in both groups); in modified ITT population, median time to clinical improvement 15 days in LPV/RTV group and 16 days in standard care only group. The 28-day mortality rate was numerically lower in LPV/RTV group (19.2% vs 25% in ITT population; 16.7% vs 25% in modified ITT population). Some evidence that LPV/RTV initiation within 12 days after symptom onset is associated with shorter time to clinical improvement. No significant differences in reduction of viral RNA load, duration of viral RNA detectability, duration of oxygen therapy, duration of hospitalization, or time from randomization to death. LPV/RTV stopped early in 13 pts because of adverse effects. 3</td>

<td><strong>LPV/RTV with ribavirin and interferon β-1b vs LPV/RTV alone in open-label, randomized trial in adults with mild to moderate COVID-19 in Hong Kong (Hung et al; NCT04276688):</strong> 127 pts were randomized 2:1 to receive LPV/RTV (LPV 400 mg/RTV 100 mg) twice daily for 14 days) with ribavirin (400 mg twice daily) and interferon β-1b (8 million IU sub-Q on alternate days for up to 3 doses depending on how soon treatment initiated after symptom onset) or a 14-day regimen of LPV/RTV alone. Median time to negative RT-PCR results for SARS-CoV-2 in nasopharyngeal samples was 7 days in pts treated with the 3-drug regimen vs 12 days in those treated with LPV/RTV alone; median duration of hospitalization was 9 or 14.5 days, respectively. Adverse effects reported in 48% of those treated with the 3-drug regimen and in 49% of those treated with LPV/RTV alone. <strong>Note:</strong> Results indicate a 3-drug regimen that included LPV/RTV, ribavirin, and interferon β-1b was more effective than LPV/RTV alone in pts with mild to moderate COVID-19, especially when treatment was initiated within 7 days of symptom onset. 25</td>

<td><strong>treatment alone</strong> (control group). Exclusion criteria included severe and critical illness. Pts assessed at baseline and 5 days after treatment initiation for time to clinical recovery (TTCR; defined as normalization of fever and cough relief maintained for &gt;72 hours), clinical characteristics, and changes on chest CT. It was concluded that hydroxychloroquine was associated with symptom relief since time to fever normalization was shorter in hydroxychloroquine group (2.2 days) vs control group (3.2 days), time to cough remission was shorter in hydroxychloroquine group, and pneumonia improved in 25/31 pts (80.6%) in hydroxychloroquine group vs 17/31 pts (54.8%) in control group. Total of 4 pts progressed to severe illness (all in the control group).**&lt;sup&gt;31&lt;/sup&gt; <strong>Note:</strong> This study did not include pts with severe disease and pts received other anti-infectives in addition to hydroxychloroquine. At study entry, 9 pts without fever and 9 pts without cough were included in hydroxychloroquine group and 14 pts without fever and 16 pts without cough were included in control group; unclear how these pts were addressed in TTCR calculations. Although initial registered study protocol specified 2 different hydroxychloroquine treatment groups and a placebo group (each with 100 pts) and primary end points of time to negative nucleic acid and T-cell recovery,&lt;sup&gt;32&lt;/sup&gt; data provided only for certain clinical symptoms in 62 pts without severe disease and PCR results not reported.&lt;sup&gt;31&lt;/sup&gt; <strong>Hydroxychloroquine randomized, parallel-group, open-label study in hospitalized adults with mild to moderate COVID-19 in China (ChiCTR2000029868):</strong> 150 pts (148 with mild to moderate disease and 2 with severe disease) were randomized 1:1 to receive hydroxychloroquine (1200 mg daily for 3 days, then 800 mg daily for total treatment duration of 2-3 weeks) with standard of care or standard of care alone. Mean time from onset of symptoms to randomization was 16.6 days (range: 3-41 days). Standard of care included IV fluids, O&lt;sub&gt;2&lt;/sub&gt;, various antivirals (e.g., umifenovir, LPV/RTV), antibiotics, and/or glucocorticoid therapy. <strong>against use of hydroxychloroquine with azithromycin for the treatment of COVID-19, except in a clinical trial.&lt;sup&gt;35&lt;/sup&gt;</strong> <strong>IDSA recommends against use of hydroxychloroquine for the treatment of COVID-19 in hospitalized pts and also recommends against use of a combined regimen of hydroxychloroquine and azithromycin for the treatment of COVID-19 in hospitalized pts.</strong>&lt;sup&gt;38&lt;/sup&gt; <strong>NIH COVID-19 Treatment Guidelines Panel recommends against the use of any agents, including hydroxychloroquine, for preexposure prophylaxis (PrEP) or postexposure prophylaxis (PEP) for prevention of SARS-CoV-2 infection, except in a clinical trial.</strong>&lt;sup&gt;35&lt;/sup&gt; The panel states that, to date, no agent is known to be effective for preventing SARS-CoV-2 infection when given before or after an exposure. Because 4-aminoquinolines (hydroxychloroquine, chloroquine) and azithromycin are independently associated with QT prolongation and because concomitant use of the drugs may further increase the risk of QT prolongation, caution is advised if considering use of hydroxychloroquine (with or without azithromycin) in pts with COVID-19, especially in outpatients who may not receive close monitoring and in those at risk for QT prolongation or receiving other drugs associated with arrhythmias.&lt;sup&gt;35, 36, 38, 39, 41-44&lt;/sup&gt; <strong>NIH panel states that 4-aminoquinolines (hydroxychloroquine, chloroquine) should be used concomitantly with drugs that pose a moderate to high risk for QT prolongation (e.g., antiarrhythmics, antidepressants, antifungals, fluoroquinolones, macrolides [including azithromycin]) only if necessary. In addition, because of the long half-lives of both hydroxychloroquine (up to 40 days) and azithromycin (up to 72 hours), caution is warranted even when these drugs are used sequentially.</strong>&lt;sup&gt;35, 39, 39, 41-44&lt;/sup&gt;</td>

<td>Hydroxychloroquine with azithromycin</td>
<td></td>
<td></td>
<td>By day 28, 73% of pts (53 treated with hydroxychloroquine with standard of care and 56 treated with standard of care alone) had converted to negative for SARS-CoV-2. The probability of negative conversion by day 28 in those treated with hydroxychloroquine was similar to that in those treated with standard of care alone; the median time to negative seroconversion (6 and 7 days) also was similar in both groups. Adverse effects reported in 30% of those treated with hydroxychloroquine and 9% of those treated with standard of care alone. Note: Results indicate that use of hydroxychloroquine in pts with mild to moderate COVID-19 did not provide additional benefits compared with use of standard of care alone.</td>
<td>of azithromycin) should be considered for empiric therapy of atypical pneumonia in COVID-19 pts receiving hydroxychloroquine (or chloroquine). 35 The benefits and risks of hydroxychloroquine (with or without azithromycin) should be carefully assessed; diagnostic testing and monitoring are recommended to minimize risk of adverse effects, including drug-induced cardiac effects. 35, 36, 38, 39, 41-44 FDA issued a safety alert regarding adverse cardiac effects (e.g., prolonged QT interval, ventricular tachycardia, ventricular fibrillation) reported with use of chloroquine or hydroxychloroquine (either alone or in conjunction with azithromycin or other drugs known to prolong QT interval) in hospital and outpatient settings; FDA cautions against use of chloroquine or hydroxychloroquine outside of a clinical trial or hospital setting and urges healthcare professionals and pts to report adverse effects involving these drugs to FDA MedWatch. 39 Emergency use authorization (EUA) for hydroxychloroquine (now revoked): Effective June 15, 2020, FDA has revoked the EUA for hydroxychloroquine and chloroquine 57 previously issued on March 28, 2020 that permitted distribution of the drugs from the strategic national stockpile (SNS) for use in adults and adolescents weighing 50 kg or more hospitalized with COVID-19 for whom a clinical trial was not available or participation not feasible. 24, 57 Based on a review of new information and reevaluation of information available at the time the EUA was issued, FDA concluded that the original criteria for issuance of the EUA for these drugs are no longer met. Based on the totality of scientific evidence available, FDA concluded that it is unlikely that hydroxychloroquine and chloroquine may be effective in treating COVID-19 and, in light of ongoing reports of serious cardiac adverse events and several newly observed cardiac effects, FDA has revoked the EUA.</td>

<tr>
<td>Hydroxychloroquine</td>
<td></td>
<td></td>
<td>Hydroxychloroquine with azithromycin open-label, nonrandomized study in France (Gautret et al): Preliminary data from an ongoing study in hospitalized pts with confirmed COVID-19 was used to assess efficacy of hydroxychloroquine used alone or with azithromycin; untreated pts were used as a negative control. The primary end point was negative PCR results in nasopharyngeal samples at day 6. Data from 14 pts treated with hydroxychloroquine sulfate (200 mg 3 times daily for 10 days), 6 pts treated with hydroxychloroquine and azithromycin (500 mg on day 1, then 250 mg daily on days 2-5), and 16 pts in the control group were analyzed. At day 6, 8/14 (57%) in the hydroxychloroquine group, 6/6 (100%) in the hydroxychloroquine and azithromycin group, and 2/16 (12.5%) in the control group had negative PCR results. At day 8, a positive PCR was reported in a pt treated with both drugs who had tested negative at day 6. Note: This was a small nonrandomized study that didn’t appear to be designed to compare hydroxychloroquine vs hydroxychloroquine and azithromycin (pts received antibiotics to prevent bacterial superinfection based on clinical judgment). Data on disease severity were unclear (some asymptomatic pts were included when study initiated) and information on disease progression and clinical outcomes was not presented.</td>

<td>Hydroxychloroquine with azithromycin open-label, uncontrolled study in France (Molina et al): 11 adults hospitalized with COVID-19 received hydroxychloroquine (600 mg daily for 10 days) and azithromycin (500 mg on day 1, then 250 mg daily on days 2-5). At time of treatment initiation, 8/11 pts had significant comorbidities associated with poor outcomes and 10/11 had fever and received O₂. Within 5 days, 1 pt died and 2 transferred to ICU; the regimen was discontinued in 1 pt after 4 days because of prolonged QT interval. Nasopharyngeal samples were still PCR positive at days 5 and 6 in 8/10 pts tested. Note: In this small uncontrolled study, hydroxychloroquine and azithromycin regimen did not result in rapid viral clearance or provide clinical benefit.</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Hydroxychloroquine with azithromycin uncontrolled, retrospective, observational study in France (Gautret et al): 80 adults with confirmed COVID-19 (including 6 pts included in a previous study by the same group) were treated with hydroxychloroquine sulfate (200 mg 3 times daily for 10 days) and azithromycin (500 mg on day 1, then 250 mg daily on days 2-5). Majority (92%) were considered low risk for clinical deterioration (low national early warning score for COVID-19 based on age, respiratory rate, O₂ saturation, temperature, BP, pulse, level of consciousness); only 15% had fever; 4 pts were asymptomatic carriers; mean time from onset of symptoms to treatment initiation was 4.9 days. Clinical outcome, contagiousness as assessed by nasopharyngeal PCR assay and culture, and length of stay in infectious disease (ID) unit were evaluated in pts who were treated for at least 3 days and followed for at least 6 days. Favorable outcome was reported for 81.3%; 15% required O₂; 3 pts transferred to ICU; 1 pt died; mean time to discharge from ID unit was 4.1 days. At day 8, PCR results were negative in 93% of those tested; at day 5, viral cultures were negative in 97.5% of those tested. Note: Almost all pts were considered low risk for clinical deterioration (including 4 pts described as asymptomatic carriers) and it is unclear reported cases of methemoglobinemia in COVID-19 patients, the known and potential benefits of hydroxychloroquine and chloroquine do not outweigh the known and potential risks associated with the use authorized by the EUA.</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

57 The basis for the FDA decision to revoke the EUA for hydroxychloroquine and chloroquine is summarized below:

1) Suggested hydroxychloroquine and chloroquine dosage regimens as detailed in the EUA fact sheets for healthcare providers are unlikely to produce an antiviral effect. 57

2) Earlier observations of decreased viral shedding with hydroxychloroquine or chloroquine treatment have not been consistently replicated and recent data from a randomized controlled trial assessing probability of negative conversion showed no difference between hydroxychloroquine and standard of care alone. 57

3) Current US treatment guidelines do not recommend the use of chloroquine or hydroxychloroquine in hospitalized patients with COVID-19 outside of a clinical trial and the NIH guidelines now recommend against such use outside of a clinical trial. 57

4) Recent data from a large, randomized, controlled trial showed no evidence of benefit in mortality or other outcomes such as hospital length of stay or need for mechanical ventilation for hydroxychloroquine treatment in hospitalized patients with COVID-19. 57

Consult the FDA letter regarding the revocation of the EUA for hydroxychloroquine and chloroquine and the FDA memorandum explaining the basis for the revocation for additional information. 57
how many would have had spontaneous conversion to negative nasopharyngeal samples during same time frame. Although 80 pts were enrolled, PCR results available for fewer pts beginning on day 3 and only 60 pts represented in day 6 data. This was an uncontrolled study and data presented cannot be used to determine whether a regimen of hydroxychloroquine with azithromycin provides benefits in terms of disease progression or decreased infectiousness, especially for pts with more severe disease.

**Hydroxychloroquine with azithromycin**

*uncontrolled, observational, retrospective analysis in France (Million et al):* Data for 1061 pts with PCR-documented SARS-CoV-2 RNA who were treated with a regimen of hydroxychloroquine sulfate (200 mg 3 times daily for 10 days) and azithromycin (500 mg on day 1, then 250 mg daily on days 2-5) were analyzed for clinical outcomes and persistence of viral shedding. Pts were included in the analysis if they received the combined regimen for at least 3 days and were clinically assessable at day 9. There were 56 asymptomatic and 1005 symptomatic pts; the majority (95%) had relatively mild disease and were considered low risk for clinical deterioration; median age was 43.6 years (range: 14-95 years) and mean time between onset of symptoms and initiation of treatment was 6.4 days. Within 10 days of treatment, good clinical outcome reported in 973 pts (91.7%) and poor clinical outcome reported in 46 pts (4.3%). Persistent nasal carriage of SARS-CoV-2 reported at completion of treatment in 47 pts (4.4%); 8 pts died. 

**Hydroxychloroquine (with or without azithromycin) in a retrospective analysis of patients hospitalized with COVID-19 in US Veterans Health Administration medical centers (Magagnoli et al):** Data for 368 males (median age >65 years) treated with hydroxychloroquine in addition to standard supportive management were analyzed for death rate and need for mechanical ventilation. Death rate was 27.8% (27/97) in those treated with hydroxychloroquine, 22.1%...

</table>
| (25/113) in those treated with hydroxychloroquine and azithromycin, and 11.4% (18/158) in those not treated with hydroxychloroquine; rate of ventilation was 13.3, 6.9, and 14.1%, respectively. Use of hydroxychloroquine alone (but not use of hydroxychloroquine and azithromycin) was associated with increased overall mortality compared with no hydroxychloroquine; use of hydroxychloroquine with or without azithromycin did not reduce the risk of mechanical ventilation. **Note:** The pt population included only elderly males 59-75 years of age, many with significant comorbidities. This analysis did not look at efficacy measures. **Two different retrospective studies analyzed outcome data for hospitalized pts with confirmed COVID-19 in New York to assess the effects of treatment with hydroxychloroquine with or without azithromycin (Rosenberg et al, Geleris et al):** Results of these studies suggest that use of hydroxychloroquine with or without azithromycin is **not** associated with decreased in-hospital mortality. **Rosenberg et al** analyzed data for 1438 hospitalized pts (735 received hydroxychloroquine with azithromycin, 271 received hydroxychloroquine alone, 211 received azithromycin alone, 221 received neither drug) and assessed in-hospital mortality (primary outcome). Overall, in-hospital mortality was 20.3%; in-hospital mortality was 25.7, 19.9, 10, or 12.7% in those treated with hydroxychloroquine with azithromycin, hydroxychloroquine alone, azithromycin alone, or neither drug, respectively. **Geleris et al** analyzed data for 1376 hospitalized pts (811 received hydroxychloroquine [486 of these also received azithromycin] and 565 did not receive hydroxychloroquine [127 of these received azithromycin]) and assessed the primary end point of time from study baseline to intubation or death. Overall, 346 pts (25.1%) progressed to a primary end point of intubation and/or death and the

<td><strong>Large, randomized, controlled, adaptive trial evaluating efficacy of 6 different treatments for prevention of death in hospitalized pts with COVID-19 compared with usual care alone (NCT04381936; RECOVERY):</strong> Study protocol included a treatment arm to evaluate efficacy of hydroxychloroquine sulfate (two 800-mg doses given 6 hours apart followed by two 400-mg doses given 12 and 24 hours after the initial dose on day 1, then 400 mg every 12 hours thereafter for 9 days). The investigators announced preliminary results for the hydroxychloroquine treatment arm. A total of 1542 pts were randomized to receive hydroxychloroquine with usual care and 3132 pts were randomized to usual care alone. Data for these pts indicate that hydroxychloroquine did not provide a significant difference in the primary end point of 28-day mortality (25.7% in those treated with hydroxychloroquine with usual care compared with 23.5% in those treated with usual care alone). In addition, there was no evidence of beneficial effects on duration of hospitalization or other outcomes. <strong>Note:</strong> Data regarding pt demographics and clinical characteristics (e.g., age, disease severity, comorbidities) and time from diagnosis to study enrollment have not been provided to date.</td>

</tbody>
</table>
greater and many had various other comorbidities: 68% received corticosteroid treatment and 4.5% received tocilizumab; mSOFA scores were not available for 25% of pts and data were not available regarding duration of symptoms prior to hospitalization; and the median length of hospitalization was 6 days. The primary end point was inpatient mortality; median follow-up was 28.5 days. Results indicated that crude mortality rates were 18.1% in the entire group, 13.5% in the hydroxychloroquine group, 20.1% in the hydroxychloroquine with azithromycin group, 22.4% in the azithromycin group, and 26.4% in those not treated with hydroxychloroquine and/or azithromycin. The primary causes of mortality were respiratory failure (88%), cardiac arrest (4%), and cardiopulmonary arrest and multi-organ failure (8%). Note: Only selected pts with minimal cardiac risk factors received hydroxychloroquine with azithromycin and all pts treated with hydroxychloroquine were monitored closely with telemetry and serial QTc evaluations. If

Open-label, randomized study in hospitalized pts with mild to moderate COVID-19 (Cavalcanti et al; Brazil; NCT04322123): Adults hospitalized with COVID-19 were randomized 1:1:1 to receive standard care (control group), hydroxychloroquine (400 mg twice daily for 7 days) with standard care, or hydroxychloroquine (same dosage) plus azithromycin (500 mg once daily for 7 days) with standard care. Pts not requiring supplemental oxygen or only requiring supplemental oxygen at a rate of 4 L/min or less at baseline were enrolled; pts with a history of severe ventricular tachycardia or with QTc of 480 msec or greater at baseline were excluded. The median time from onset of symptoms to randomization was 7 days. The primary outcome was clinical status at day 15 evaluated using a 7-point ordinal scale. Data for the 504 pts in the modified intention-to-treat population with laboratory-confirmed COVID-19 (173 pts in the control group, 159 pts in the hydroxychloroquine group, 172 pts in the hydroxychloroquine and azithromycin group) indicated there was no significant

**Open-label, randomized study in outpatients with mild COVID-19 (Mitja et al; Spain):** Total of 293 adults with laboratory-confirmed COVID-19 who did not require hospitalization and had mild symptoms (i.e., fever, acute cough, shortness of breath, sudden olfactory or gustatory loss, influenza-like illness) for less than 5 days before study enrollment were randomized 1:1 to receive hydroxychloroquine (800 mg on day 1, then 400 mg once daily for 6 days) or usual care only. The primary outcome was reduction of viral RNA load in nasopharyngeal swabs at days 3 and 7 after treatment initiation. Median age of pts was 41.6 years, 53% reported chronic health conditions, and 87% were healthcare workers. The median time from symptom onset to randomization was 3 days, and the mean viral load at baseline was 7.9 log10 copies/mL. Results indicated that a 7-day hydroxychloroquine regimen did not provide any clinical benefits compared with usual care alone in these outpatients with mild COVID-19. There was no significant reduction in viral load at day 3 or 7 in those treated with hydroxychloroquine vs those treated with usual care only and there was no decrease in median time to resolution of COVID-19 symptoms (10 and 12 days, respectively) and no decrease in risk of hospitalization (7 and 6%, respectively). 59

**Double-blind, randomized, placebo-controlled study in outpatients with confirmed or probable early COVID-19 (Skipper et al; US and Canada; NCT04308668):** A total of 423 symptomatic adults with laboratory-confirmed COVID-19 or with symptoms compatible with COVID-19 and a high-risk exposure to a contact with laboratory-confirmed...
COVID-19 were randomized 1:1 to receive hydroxychloroquine (initial dose of 800 mg, 600 mg given 6-8 hours later, then 600 mg once daily for the next 4 days) or placebo. Enrolled pts had been symptomatic for no more than 4 days and did not require hospitalization at the time of enrollment. The primary efficacy end point specified in the initial study protocol was subsequently changed to overall symptom severity over 14 days; symptoms and severity were self-reported by the pts at days 3, 5, 10, and 14 using a survey with a 10-point visual analog scale. Median age of pts was 40 years, 68% reported no chronic medical conditions, 57% were healthcare workers, 25% had been exposed to COVID-19 through household contacts, and 56% of pts had enrolled within 1 day of symptom onset. Results indicated that a 5-day hydroxychloroquine regimen did not provide any substantial improvement in symptom severity in these outpatients with confirmed or probable COVID-19. At day 5, 54% of pts in the hydroxychloroquine group and 56% in the placebo group reported symptoms. At day 14, 24% of those treated with hydroxychloroquine had ongoing symptoms compared with 30% of those treated with placebo. Overall, the decrease in prevalence of symptoms and the reduction in symptom severity score over 14 days were not significantly different between the two groups (symptom severity in the 10-point scale decreased 2.6 points in those treated with hydroxychloroquine and 2.3 points in those treated with placebo). In addition, there was no difference between the groups in the incidence of hospitalization or death.

Large, multinational, retrospective study analyzed outcome data for hospitalized pts with confirmed COVID-19 to assess the effects of hydroxychloroquine or chloroquine used with or without a macrolide (Mehra et al; now retracted): Original publication included data obtained worldwide for 96,032 pts hospitalized with COVID-19 between Dec 20, 2019 and Apr 14, 2020, including 14,888 pts who received chloroquine or hydroxychloroquine with or without a macrolide (azithromycin...

<td>or clarithromycin</td>
<td></td>
<td></td>
<td>initiated within 48 hours of diagnosis (treatment group) and 81,144 pts who did not receive these drugs (control group). Based on those data, inhospital mortality rate in the control group was 9.3% compared with 18% in those treated with hydroxychloroquine alone (n=3016), 23.8% in those treated with hydroxychloroquine and a macrolide (n=6221), 16.4% in those treated with chloroquine alone (n=1868), and 22.2% in those treated with chloroquine and a macrolide (n=3783). Note: This published study has now been retracted by the publisher at the request of 3 of the original authors. Concerns were raised with respect to the veracity of the data and analyses conducted by a global healthcare data collaborative. Hydroxychloroquine for postexposure prophylaxis of COVID-19 randomized, placebo-controlled trial in the US and Canada (NCT04308668): Asymptomatic adults with occupational or household exposure to an individual with COVID-19 were randomly assigned 1:1 to receive postexposure prophylaxis with a 5-day regimen of hydroxychloroquine sulfate (initial 800-mg dose followed by a 600-mg dose given 6-8 hours after first dose on day 1, then 600 mg once daily for 4 additional days) or placebo (folate tablets). A total of 821 asymptomatic adults were enrolled within 4 days after COVID-19 exposure (414 randomized to hydroxychloroquine and 407 randomized to placebo); 66% were healthcare workers. Overall, 88% of participants reported high-risk exposures (occurred at a distance of &lt;6 feet for &gt;10 minutes while not wearing a face mask or eye shield) and the others reported moderate-risk exposures (occurred at a distance of &lt;6 feet for &gt;10 minutes while wearing a face mask but no eye shield). Note: Participants were recruited primarily through social media outreach and traditional media platforms and were enrolled using an internet-based survey. The exposure event and subsequent onset of new symptoms and illness compatible with COVID-19 after enrollment were self-reported using email</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
surveys on days 1, 5, 10, and 14 and at 4-6 weeks. Results of these surveys and information obtained using additional forms of follow-up indicated that confirmed or probable COVID-19 (based on self-reported symptoms or PCR testing) developed in 13% of participants overall (107/821) and did not differ significantly between those who received hydroxychloroquine prophylaxis (11.8%) and those who received placebo (14.3%). Note: The various limitations of the trial design should be considered when interpreting the results. Exposure to someone with confirmed COVID-19, time from the exposure event to initiation of prophylaxis, and all outcome data (including possible COVID-19 symptoms and PCR test results) were self-reported by study participants. COVID-19 was confirmed with PCR testing in only a small percentage (<3%) of participants who self-reported COVID-19 symptoms. Survey results indicated that full adherence to the 5-day prophylaxis regimen was reported by only 75% of patients randomized to hydroxychloroquine and 83% of those randomized to placebo. In addition, a total of 52 participants did not complete any surveys after study enrollment.

Multiple clinical trials to evaluate hydroxychloroquine for treatment of COVID-19 are registered at clinicaltrials.gov (some listed below): 10

<td>Remdesivir</td>
<td>Remdesivir</td>
<td>In Rhesus macaques infected with SARS-CoV-2, treatment with a 6-day regimen of IV remdesivir initiated 12 hours after virus inoculation was associated with some benefits (lower disease severity scores, fewer pulmonary infiltrates, lower virus titers in bronchoalveolar lavage samples) compared with vehicle control; remdesivir treatment did not reduce viral loads or infectious virus titers in nose, throat, or rectal swabs compared with vehicle control. In vitro activity against SARS-CoV and MERS-CoV; active in animal models of SARS and MERS; prevented MERS in Rhesus macaques when given before infection and provided benefits when given after animal already infected. Pharmacokinetic data available from evaluations for Ebola.</td>
<td></td>
<td>IV infusion once daily from day 1. For pts not requiring invasive mechanical ventilation and/or ECMO, recommended total treatment duration is 5 days; if pt does not demonstrate clinical improvement, treatment may be extended for up to 5 additional days (i.e., up to a total treatment duration of 10 days). For those requiring invasive mechanical ventilation and/or ECMO, recommended total treatment duration is 10 days. Emergency use authorization (EUA) remdesivir dosage and duration of treatment recommended for hospitalized children weighing 3.5 to less than 40 kg (using the lyophilized powder formulation only): Loading dose of 5 mg/kg by IV infusion on day 1, followed by maintenance doses of 2.5 mg/kg by IV infusion once daily from day 2. For pts not requiring invasive mechanical ventilation and/or ECMO, recommended total treatment duration is 5 days; if pt does not demonstrate clinical improvement, treatment may be extended for up to 5 additional days (i.e., up to a total treatment duration of 10 days). For those requiring invasive mechanical ventilation and/or ECMO, recommended total treatment duration is 10 days. NIH COVID-19 Treatment Guidelines Panel-recommended duration of remdesivir treatment when supplies are limited: The NIH panel recommends that hospitalized pts who require supplemental oxygen, but are not on high-flow oxygen, noninvasive ventilation, mechanical ventilation, or ECMO, receive remdesivir for a duration of 5 days or until hospital discharge, whichever comes first. If the pt progresses to requiring high-flow oxygen, noninvasive ventilation, mechanical ventilation, or ECMO during such treatment, the panel recommends that the remdesivir course be completed.</td>
<td>May 1, 2020 that permitted use of the drug for the treatment of COVID-19 only in hospitalized adults and children with suspected or laboratory-confirmed COVID-19 and severe disease (defined as oxygen saturation [SpO2] 94% or lower on room air or requiring supplemental oxygen, mechanical ventilation, or ECMO). On August 28, 2020, FDA broadened the EUA for remdesivir to include treatment of all hospitalized adults and pediatric patients with suspected or laboratory-confirmed COVID-19, irrespective of disease severity. The EUA requires that the drug be administered by a healthcare provider in an inpatient hospital setting via IV infusion at dosages recommended in the EUA. Distribution of remdesivir under this EUA is being directed by the HHS Office of the Assistant Secretary for Preparedness and Response (ASPR) in collaboration with state health departments. HHS announced that, beginning October 1, 2020, healthcare providers should contact the sole distributor (AmerisourceBergen) to purchase remdesivir for use under the EUA. The EUA requires that healthcare facilities and healthcare providers administering remdesivir comply with certain mandatory record keeping and reporting requirements (including adverse event reporting to FDA MedWatch). Consult the EUA, EUA fact sheet for healthcare providers, and EUA fact sheet for patients and parents/caregivers for additional information. The NIH COVID-19 Treatment Guidelines Panel issued guidelines regarding prioritizing use of remdesivir when supplies are limited: The panel recommends the drug be prioritized for use in hospitalized pts with COVID-19 who require supplemental oxygen, but are not on high-flow oxygen, noninvasive ventilation, mechanical ventilation, or ECMO, because efficacy in this pt population has been demonstrated. (For recommendations on treatment duration in such pts, see Dosage.) The NIH...</td>

### Drug(s)
- Drug(s): Remdesivir

### AHFS Class
- AHFS Class: 120, 20

### Rationale
- Rationale: The current version of this document can be found on the ASHP COVID-19 Resource Center.

### Trials or Clinical Experience
- **Phase 3 trial in adults and children ≥12 years of age with severe COVID-19 (NCT04292899; SIMPLE-Severe):**
  - 200 mg IV on day 1, then 100 mg IV daily on days 2-5 (arm 1) or 200 mg IV on day 1, then 100 mg IV daily on days 2-10 (arm 2).
  - 200 mg IV on day 1, then 100 mg IV daily on days 2-10 (extension arms that include pts who are not receiving mechanical ventilation or ECMO at baseline). (See Trials or Clinical Experience.)

- **Phase 3 trial in adults and children ≥12 years of age with moderate COVID-19 (NCT04292730; SIMPLE-Moderate):**
  - 200 mg IV on day 1, then 100 mg IV daily on days 2-5 (arm 1) or 200 mg IV on day 1, then 100 mg IV daily on days 2-10 (arm 2).

### Dosage
- **Dosage:**
  - a: 200 mg IV on day 1, then 100 mg IV daily on days 2-5 (arm 1) or 200 mg IV on day 1, then 100 mg IV daily on days 2-10 (arm 2).

### Comments
- **Comments:** The panel states that there are insufficient data on the optimal duration of remdesivir treatment for pts who have not shown clinical improvement after a 5-day regimen; some experts would extend the total duration of remdesivir treatment to up to 10 days in these patients.

- **Concomitant use of remdesivir and chloroquine or hydroxychloroquine is not recommended:**
  - Concomitant use of remdesivir and drugs that are strong inducers of cytochrome P-450 (CYP) isoenzymes (e.g., rifampin) is not recommended; remdesivir plasma concentration may be modestly reduced and the clinical relevance of such decreased concentrations is unknown. Although drug interaction studies have not been performed to date, remdesivir plasma concentrations are unlikely to be substantially altered by concomitant use with drugs that are weak to moderate inducers or strong inhibitors of CYP isoenzymes, P-glycoprotein (P-gp), or organic anion transport polypeptide (OATP).

<tr>
<td></td>
<td></td>
<td></td>
<td><strong>retrospective cohort of patients:</strong> The manufacturer announced results of an analysis that compared data for 312 hospitalized pts with severe COVID-19 who received remdesivir in this randomized, open-label trial with a retrospective cohort of 818 pts with similar baseline characteristics and disease severity who received standard of care treatment (without remdesivir) during the same time period. More than 90% of pts in both groups were enrolled at North American trial sites and the rest were enrolled at European or Asian trial sites. Clinical recovery (improvement in clinical status based on a 7-point ordinal scale) and mortality rate for these 2 groups were compared. By day 14, recovery was reported in 74.4% of pts treated with remdesivir and 59% of pts in the retrospective cohort treated with standard of care and the mortality rate was 7.6 and 12.5%, respectively.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td><strong>Subgroup analyses of data from Phase 3 SIMPLE-Severe trial:</strong> The manufacturer announced results of subgroup analyses of 229 hospitalized pts with severe COVID-19 who received remdesivir in this randomized, open-label trial and were enrolled at US trial sites. Clinical improvement was defined as a 2-point or greater improvement on a 7-point ordinal scale. At day 14, the rate of clinical improvement was 84% in black pts (n=43), 76% in Hispanic white pts (n=17), 67% in Asian pts (n=18), 67% in non-Hispanic white pts (n=119), and 63% in pts who did not identify with any of these groups (n=32). An analysis of 397 pts who were enrolled globally indicated that black race, age less than 65 years, treatment outside of Italy, and requirement of only low-flow oxygen support or room air at baseline were factors significantly associated with clinical improvement of at least 2 points on day 14. Another subgroup analysis was performed to evaluate outcomes in pts who received concomitant therapy with remdesivir and hydroxychloroquine vs those who received only remdesivir. At a median follow-up of 14 days, the rates and likelihood of recovery were lower in those treated with both drugs (57%) compared</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
with those treated with remdesivir alone (69%). Although concomitant hydroxychloroquine was not associated with increased mortality at 14 days, the overall rate of adverse effects was higher and, after adjusting for baseline variables, the incidence of grade 3-4 adverse events was significantly higher in those treated with both drugs.

**Phase 3 randomized, open-label trial in hospitalized pts with moderate COVID-19 (NCT04292730; GS-US-540-5774; SIMPLE-Moderate)** sponsored by the manufacturer (Gilead): Initial study protocol was designed to evaluate safety and antiviral activity of 5- and 10-day regimens of remdesivir (200 mg IV on day 1, followed by 100 mg IV once daily for total of 5 or 10 days) in conjunction with standard of care compared with standard care alone in adults with moderate COVID-19 (i.e., hospitalized with evidence of pulmonary infiltrates and SpO₂ >94% on room air); protocol was subsequently modified to change the primary end point to clinical status on day 11 based on a 7-point ordinal scale, include pts 12 years of age or older, and add an extension phase to include additional pts. Data for the initial group of adults who received a 5-day regimen of remdesivir with standard care (n=191), 10-day regimen of the drug with standard care (n=193), or standard care alone (n=200) have been published. At day 11, 70, 65, or 61% of pts in the 5-day, 10-day, or standard of care alone group, respectively, had clinical improvement based on at least a 2-point improvement from baseline on a 7-point ordinal scale. Pts in the 5-day remdesivir group had statistically significant higher odds of a better clinical status distribution on the 7-point scale on day 11 than those receiving standard care (odds ratio: 1.65) but the difference was of uncertain clinical importance; the difference in clinical status distribution between pts in the 10-day remdesivir group and the standard care group was not statistically significant. At day 11, 4 deaths were reported in the standard care alone group compared with none in the 5-day group and 2 in the...
Phase 3 adaptive, randomized, double-blind, placebo-controlled trial (NCT04280705; NIAID Adaptive COVID-19 Treatment Trial 1 [ACTT-1]) in hospitalized adults with COVID-19: 1063 pts were randomized 1:1 to receive remdesivir (200 mg IV on day 1, then 100 mg IV once daily on days 2-10 or until hospital discharge or death) or placebo. All pts received supportive care according to the standard of care for the trial site hospital. Baseline demographics and clinical characteristics (e.g., age, disease severity, comorbidities at study enrollment, time to initiation of treatment after symptom onset) were similar in both groups. Overall, 88.7% of pts had severe disease at study enrollment and the median time from symptom onset to randomization was 9 days (range: 6-13 days). Preliminary data analysis that included 1059 pts (538 randomized to remdesivir and 521 randomized to placebo) indicated shorter median time to recovery in the remdesivir group (11 days) vs the placebo group (15 days) and suggested that remdesivir treatment may have provided a survival benefit (Kaplan-Meier estimates of mortality by day 14 were 7.1% in the remdesivir group vs 11.9% in the placebo group). Based on preliminary subgroup analyses, the benefit of remdesivir was most apparent in the 421 pts who required 10-day group. There were no significant differences between the 5- or 10-day remdesivir groups and standard care group for any of the exploratory end points at day 11 (time to 2-point or greater improvement in clinical status, time to 1-point or greater improvement in clinical status, time to recovery, time to modified recovery, time to discontinuation of oxygen support). At day 14, the clinical status of pts in the 5-day and 10-day remdesivir groups was significantly different than that of the standard care group. Note: Effect of remdesivir on SARS-CoV-2 viral load was not assessed. Limitations of this study include the open-label design and use of an ordinal scale to evaluate outcomes that was not ideal for detecting differences in pts with moderate COVID-19.

**Data from the manufacturer’s compassionate use program (adults):** Preliminary data are available for a cohort of 53 adults from multiple sites in the US, Italy, Japan, and other countries who were hospitalized with severe COVID-19 and received treatment with remdesivir; 40 pts received the full 10-day regimen (200 mg IV on day 1, then 100 mg IV on days 2-10), 10 pts received 5-9 days and 3 pts received less than 5 days of treatment with the drug. At baseline, 30 pts (57%) were receiving mechanical ventilation and 4 (18%) were receiving extracorporeal membrane oxygenation (ECMO). Over a median follow-up of 18 days after first dose, 36 pts (68%) showed clinical improvement based on oxygen-support status and 8 pts (15%) worsened. There were 7 deaths (13%), including 6 pts receiving invasive ventilation. Adverse effects (e.g., increased hepatic enzymes, diarrhea, rash, renal impairment, hypotension) were reported in 32 pts (60%); 12 pts (23%) had serious adverse effects (e.g., multiple organ dysfunction syndrome, septic shock, acute kidney injury, hypotension); 4 pts (8%) discontinued the drug because of adverse effects. **Note:** Data presented for this small cohort of pts offers only limited information regarding efficacy and safety of remdesivir for treatment of COVID-19. There was no control group and, although supportive therapy could be provided at the discretion of the clinician, it is unclear whether pts at any of the various study sites also received other therapeutic agents being used for treatment of COVID-19. In addition, data were not presented regarding the effects of remdesivir on viral load. |         |          |

**Data from the manufacturer’s compassionate use program (pediatric pts):**
Drug(s) | AHFS Class | Rationale | Trials or Clinical Experience | Dosage | Comments
---|---|---|---|---|---
The manufacturer announced that preliminary data are available for 77 pediatric pts treated with remdesivir in the compassionate use program. Analysis of day-28 data indicated that 73% of these pediatric pts were discharged from the hospital, 12% remained hospitalized but on ambient air, and 4% had died. There were 39 critically ill pediatric pts who required invasive mechanical ventilation at baseline and 80% of these pts recovered; there were 38 pediatric pts who did not require invasive ventilation and 87% of these pts recovered. No new safety signals were identified for remdesivir in this population. 

Data from the manufacturer’s compassionate use program (pregnant and postpartum women): The manufacturer announced that preliminary data are available for 86 pregnant and postpartum women treated with remdesivir in the compassionate use program. Analysis of data for these pts (median age 33 years) indicated that 96% of the pregnant women and 89% of the postpartum women achieved improvement in oxygen support levels. Those with more severe illness at baseline achieved similarly high rates of clinical recovery (93 or 89% in those who were pregnant or postpartum, respectively). Pregnant women not on invasive oxygen support at baseline had the shortest median time to recovery (5 days), and both pregnant and postpartum women on invasive ventilation at baseline had similar median times to recovery (13 days). No new safety signals were identified for remdesivir in this population; the most common adverse events were due to underlying disease and most laboratory abnormalities were grades 1–2.

Phase 2/3 single-arm, open-label trial in pediatric patients (NCT04431453; CARAVAN): The manufacturer (Gilead) initiated a trial to evaluate safety, tolerability, pharmacokinetics, and efficacy of remdesivir in pediatric pts (birth to <18 years of age) with laboratory-confirmed COVID-19.

**Updated 8/20/20**

**Umifenovir (Arbidol®)**

**Updated 8/20/20**

8:18.92 Antiviral

Broad-spectrum antiviral with in vitro activity against various viruses, including coronaviruses 4 Although data limited, in vitro activity against SARS-CoV-1 4 and SARS-CoV-2 5 reported

Licensed in China, Russia, Ukraine, and possibly other countries for prophylaxis and treatment of influenza 4

Retrospective cohort study in 50 adults with COVID-19 in China suggests better viral suppression with umifenovir vs LPV/RTV. All pts received conventional therapy, including interferon α-2b. At 7 days after hospital admission, SARS-CoV-2 was undetectable in 50% of pts treated with umifenovir vs 23.5% treated with LPV-RTV; at 14 days, viral load undetectable in all pts treated with umifenovir vs 44.1% treated with LPV/RTV. Duration of positive SARS-CoV-2 RNA positive test was shorter with umifenovir vs LPV-RTV 8

Dosage used or being investigated in COVID-19 clinical trials: 200 mg orally 3 times daily for duration of 7-10 days or longer 2, 3, 6, 8

Dosage recommended for treatment of COVID-19 in China: Adults, 200 mg orally 3 times daily for no more than 10 days 5, 7

Not commercially available in the US Included in some guidelines for treatment of COVID-19 7 Efficacy for the treatment of COVID-19 not established

| Anakinra (Kineret®) *Updated 10/1/20* | 92:36 Disease-modifying Anti-rheumatic Drug | Recombinant human interleukin-1 (IL-1) receptor antagonist ¹  
IL-1 levels are elevated in patients with COVID-19; anakinra may potentially combat cytokine release syndrome (CRS) symptoms in severely ill COVID-19 patients ⁵,¹,³,⁷  
Anakinra has been used off-label for severe chimeric antigen receptor T cell (CAR T-cell)-mediated cytokine release syndrome (CRS) and macrophage activation syndrome (MAS)/secondary hemophagocytic lymphohistocytosis. IL-1 levels are elevated in patients with these conditions. Case reports and series describe a favorable response to anakinra in these syndromes, including survival benefit in sepsis and reversing cytokine storm in adults with MAS after tocilizumab failure.⁷ | There are case study data but no known published prospective clinical trial evidence supporting efficacy or safety of anakinra for treatment of COVID-19 ⁷  
France: A cohort study (Ana-COVID) included a prospective cohort of 52 adults with severe COVID-19 treated with anakinra plus standard of care and a historical comparison group of 44 patients who received standard and supportive care at Groupe Hospitalier Paris Saint-Joseph. Inclusion criteria included severe COVID-19-associated bilateral pneumonia on chest x-ray or lung CT scan, laboratory-confirmed SARS-CoV-2 or typical lung infiltrates on a lung CT scan, and an oxygen saturation of ≤93% under oxygen 2 L/min or deterioration (saturation ≤93% under oxygen 3 L/min with loss of 3% oxygen saturation in ambient air over previous 24 hours). Anakinra was given subcutaneously in a dosage of 100 mg twice daily on days 1–4, then 100 mg once daily from day 4–10. The primary outcome measure was a composite of either ICU admission for invasive mechanical ventilation or death. Admission to the ICU or death occurred in 13 (25%) of anakinra-treated patients and in 32 (73%) of patients in the historical comparison group.⁵  
France: A small case series (9 patients) of open-label anakinra treatment in hospitalized (non-ICU) adults with moderate to severe COVID-19 pneumonia has been published with encouraging results ⁸  
Italy: Retrospective cohort study (part of NCT04318366) with high- or low-dose anakinra in adults with COVID-19, moderate to severe acute respiratory distress syndrome (ARDS), and hyperinflammation (defined as elevated serum C-reactive protein [CRP] and/or ferritin levels) managed with non-invasive ventilation outside of the ICU at a Milan hospital. Patients received standard therapy (hydroxychloroquine and lopinavir/ritonavir) and either high-dose anakinra | Various dosage regimens are being studied ¹,⁸  
Trial protocol in Italy (COVID-19 with hyperinflammation and respiratory distress): 100 mg by IV infusion every 6 hours (total of 400 mg daily) for 15 days ³  
Some studies under way in Europe are evaluating 100 mg given subcutaneously once daily for 10 or 28 days, respectively, or until hospital discharge ³  
In a French case series and a French cohort study, anakinra was given subcutaneously in a dosage of 100 mg twice daily (i.e., every 12 hours) on days 1–3, then 100 mg once daily from day 4–10 ⁸,⁹  
A retrospective cohort study in Italy compared high-dose anakinra by IV infusion (5 mg/kg twice daily) and low-dose anakinra (100 mg twice daily) given subcutaneously ¹⁰  
(Note: Anakinra is approved only for subcutaneous administration in the U.S.) ¹ ⁷ | NIH COVID-19 Treatment Guidelines Panel states that there are insufficient clinical data to recommend either for or against use of anakinra in the treatment of COVID-19 ⁷  
Safety profile: Well established in adults with sepsis and has been studied extensively in severely ill pediatric patients with complications of rheumatologic conditions; pediatric data on use in acute respiratory distress syndrome/sepsis are limited ⁷  
Pregnancy: Limited evidence to date: unintentional first trimester exposure considered unlikely to be harmful ⁷ |

|         |            | effects, including effects on proinflammatory cytokines; precise mechanisms of such effects not fully elucidated 2, 6, 8, 9, 11-14, 17 Has been used as adjunctive therapy to provide antibacterial coverage and potential immunomodulatory and anti-inflammatory effects in the treatment of some viral respiratory tract infections (e.g., influenza) 10, 13 Has been used as adjunctive therapy to provide antibacterial coverage and potential immunomodulatory and anti-inflammatory effects in the management of certain respiratory conditions (e.g., bronchiectasis, bronchiolitis, cystic fibrosis, COPD exacerbations, ARDS) 6, 8, 17 who received macrolide therapy and those who did not. 12 Adjunctive therapy in certain respiratory conditions: Some evidence of beneficial immunomodulatory or anti-inflammatory effects when used in pts with certain respiratory conditions (e.g., ARDS). 8 In a retrospective cohort study in pts with moderate or severe ARDS, a statistically significant improvement in 90-day survival was reported in those who received adjunctive azithromycin. 8 Clinical experience in pts with COVID-19: Has been used for antibacterial coverage in hospitalized pts with COVID-19 15 Use in conjunction with hydroxychloroquine in pts with COVID-19: Azithromycin (500 mg on day 1, then 250 mg daily on days 2-5) has been used in addition to a 10-day regimen of hydroxychloroquine (500 mg daily) in an open-label nonrandomized study in France (6 pts), 7 open-label uncontrolled study in France (11 pts), 26 uncontrolled observational study in France (80 pts), 26 and larger uncontrolled observational study in France (1061 pts). 26 Data presented to date are insufficient to evaluate possible clinical benefits of azithromycin in pts with COVID-19. (See Hydroxychloroquine in this Evidence Table.) Use in conjunction with hydroxychloroquine in hospitalized pts with COVID-19: Data from 2 retrospective studies that analyzed outcome data for hospitalized pts in New York treated with hydroxychloroquine with or without azithromycin indicate that use of the 4-aminoquinoline antimalarial with or without azithromycin is not associated with decreased in-hospital mortality. 30, 31 (See Hydroxychloroquine in this Evidence Table.) Multiple clinical trials to evaluate azithromycin alone or azithromycin with hydroxychloroquine or chloroquine for treatment of COVID-19 are registered at clinicaltrials.gov (some listed below): 23 pneumonia or sepsis is strongly suspected or confirmed, empiric antibacterial treatment should be administered. 21, 32 Although data are limited, bacterial pathogens in COVID-19 pts with community-acquired pneumonia (CAP) are likely the same as those seen in other pts with CAP. Therefore, if antibacterial coverage for CAP is indicated in COVID-19 pts, the usually recommended regimen for empiric treatment of CAP should be used. 32 Antimicrobial stewardship policies should be used to guide appropriate use of antibacterials in COVID-19 pts. 21 Data from randomized, controlled clinical trials are insufficient to date to draw conclusions regarding possible benefits of using a combined regimen of hydroxychloroquine and azithromycin for the treatment of COVID-19; there are data indicating that combined use of azithromycin and chloroquine or hydroxychloroquine may be associated with an increased risk of adverse cardiac effects. 21, 22, 33 NIH COVID-19 Treatment Guidelines Panel recommends against the use of a combined regimen of hydroxychloroquine and azithromycin for the treatment of COVID-19, except in the context of a clinical trial, because of the potential for toxicities. 21 (See Hydroxychloroquine in this Evidence Table.) IDSA recommends against use of a combined regimen of hydroxychloroquine (or chloroquine) and azithromycin for the treatment of COVID-19 in hospitalized pts. 22 Because azithromycin and 4-aminoquinolines (hydroxychloroquine, chloroquine) are independently associated with QT prolongation, caution is advised if considering use of azithromycin with one of these drugs in pts with COVID-19, especially in outpatients who may not receive close monitoring and in those at risk for QT prolongation or

<sup>a</sup>Dosage information is based on the drug’s approved indication in the U.S. and may differ in other countries. It is important to use colchicine cautiously in patients with renal or hepatic impairment, thrombocytopenia, or a history of gout. 

**Notes:**
- Colchicine is typically dosed once daily in patients with normal renal and hepatic function and weight >60 kg.
- There is limited data on the use of colchicine in children, elderly, and those with severe renal impairment.
- Colchicine is not recommended in patients with gout or colchicine hypersensitivity.
- Colchicine use is contraindicated in patients with gout.

**Corticosteroids (systemic)**

**Updated 9/24/20**

68:04 Adrenals

Potent anti-inflammatory and antifibrotic properties; use of corticosteroids may prevent an extended cytokine response and may accelerate resolution of

Observational studies in other respiratory infections (e.g., SARS, MERS, influenza): In these studies, corticosteroid use was associated with no survival benefit and possible harm (e.g., delayed viral clearance, avascular necrosis, psychosis, diabetes).<sup>1,24,25</sup>

The NIH COVID-19 Treatment Guidelines Panel recommends an IV or oral Dexamethasone dosage of 6 mg daily for up to 10 days or until hospital discharge, whichever comes<sup>3,5,7,24,25</sup>

Data on the use of corticosteroids in COVID-19 are limited.<sup>3,5,7,24,25</sup> The benefits and risks of corticosteroid therapy should be carefully weighed before use in patients with COVID-19.<sup>1,7</sup>
### Drug(s) | AHFS Class | Rationale | Trials or Clinical Experience | Dosage | Comments
--- | --- | --- | --- | --- | ---
Dexamethasone | | **Pulmonary and systemic inflammation in pneumonia** 1, 9 Evidence suggests that cytokine storm, a hyperinflammatory state resembling secondary hemophagocytic lymphohistiocytosis (HLH), is a contributing factor in COVID-19-associated mortality. 8, 18 Immunosuppression from corticosteroids has been proposed as a treatment option for such hyperinflammation. 18 May improve dysregulated immune response caused by sepsis (possible complications from pulmonary and systemic infection with COVID-19) and increase BP when low 4, 11 | Randomized controlled studies in acute respiratory distress syndrome (ARDS): Systemic corticosteroid therapy has been studied in several randomized controlled studies for the treatment of ARDS; overall evidence is low to moderate in quality and most studies were performed prior to widespread implementation of lung protection strategies. 5, 6, 9, 14, 17 Randomized, controlled, open-label, adaptive trial with a Dexamethasone arm (NCT04381936; RECOVERY): This trial was conducted to evaluate the effect of potential treatments (including low-dose dexamethasone) on all-cause mortality in hospitalized patients with COVID-19. The study enrolled patients with suspected or confirmed COVID-19 from 176 hospitals in the UK. In the dexamethasone treatment arm, 21,042 patients randomized to receive dexamethasone (6 mg once daily orally or IV for up to 10 days) plus standard care and 4321 patients were randomized to receive standard care alone. Preliminary data analysis indicates that overall 28-day mortality was reduced in patients receiving dexamethasone compared with those receiving standard care alone with the greatest benefit observed in patients requiring mechanical ventilation at enrollment. Overall, 22.9% of patients receiving dexamethasone and 25.7% of those receiving standard care died within 28 days of study enrollment. In patients receiving dexamethasone, the incidence of death was lower than that in the standard care group among those receiving invasive mechanical ventilation (29.3 vs 41.4%) and among those receiving supplemental oxygen without invasive mechanical ventilation (23.3 vs 26.2%). However, no survival benefit was observed with dexamethasone and there was a possibility of harm in patients who did not require respiratory support at enrollment; the incidence of death in such patients receiving dexamethasone compared with standard care was 17.8 vs 14%, respectively. Dexamethasone was associated with a reduction in 28-day mortality among patients with symptoms for >7 days | **First**, in COVID-19 patients requiring mechanical ventilation and in patients who require supplemental oxygen but who are not mechanically ventilated. Although the clinical benefits of other corticosteroids (e.g., hydrocortisone, methylprednisolone, prednisone) are not clear, the panel recommends using total daily dosages of these drugs equivalent to dexamethasone 6 mg (IV or oral) as follows: Hydrocortisone 160 mg, Methylprednisolone 32 mg, or Prednisone 40 mg. Based on half-life and duration of action, frequency of administration varies among these corticosteroids. Dexamethasone is long-acting and administered once daily. Methylprednisolone and Prednisone are intermediate-acting and administered once daily or in 2 divided doses daily. Hydrocortisone is short-acting and administered in 2-4 divided doses daily. 24 Regimens used in early cases of COVID-19 in China were typically methylprednisolone 40-80 mg IV daily for a course of 3-6 days. Some experts suggest that equivalent dosages of dexamethasone (i.e., 7-15 mg daily, typically 10 mg daily) may have an advantage of preventing less fluid retention, since dexamethasone has less mineralocorticoid activity. 8 This dosage of dexamethasone is consistent with those used in the DEXA-ARDS trial. 8, 11 However, lower dosages of dexamethasone (i.e., 6 mg once daily for 10 days) were used in the RECOVERY trial. 22, 23 Higher dosages of IV Dexamethasone (i.e., 20 mg once daily for 5 days followed by 10 mg once daily for an additional 5 days or until ICU discharge, whichever came first) were used in the CoDEX trial in patients with COVID-19 and moderate or severe ARDS. 29 | NIH, CDC, WHO, IDSA, and other experts have issued guidelines for the use of corticosteroids in patients with COVID-19 based on the currently available information. Recommendations are made according to the severity of illness, indications, and underlying medical conditions and should be considered on a case-by-case basis. 1, 2, 8, 12, 24, 25, 43 Non-critical patients: Corticosteroids generally should not be used in the treatment of early or mild disease since the drugs can inhibit immune response, reduce pathogen clearance, and increase viral shedding. 3, 8, 24 The WHO Guideline Development Group suggests not using systemic corticosteroids in the treatment of patients with non-severe COVID-19, regardless of hospitalization status. However, if the clinical condition of such non-severe patients worsens (e.g., increased respiratory rate, signs of respiratory distress, or hypoxemia), systemic corticosteroids are recommended for treatment. The WHO Guideline Development Group recommends against discontinuing systemic corticosteroids in patients with non-severe COVID-19 who are receiving systemic corticosteroids for chronic conditions (e.g., COPD, autoimmune diseases). 43 Critically ill patients: The Surviving Sepsis Campaign COVID-19 subcommittee (a joint initiative of the Society of Critical Care Medicine and the European Society of Intensive Care Medicine) recommends against the routine use of systemic corticosteroids in mechanically ventilated adults with COVID-19 and respiratory failure (without ARDS). 12 However, these experts generally support a weak recommendation to use low-dose, short-duration systemic corticosteroids in the sickest patients with COVID-19 and ARDS. 12 Based on preliminary findings from the RECOVERY trial, the NIH COVID-19...

<td>Dexamethasone</td>
<td>ASHP COVID-19</td>
<td>Rationale</td>
<td>Compared with those having more recent symptom onset. Dexamethasone treatment also was associated with a shorter duration of hospitalization and a greater probability of discharge within 28 days with the greatest effect observed among patients receiving invasive mechanical ventilation at baseline. Note: Data regarding potential adverse effects, efficacy in combination with other treatments (e.g., remdesivir), and efficacy in other patient populations (e.g., pediatric patients and pregnant women) not available to date.</td>
<td>Continuous IV infusion of Hydrocortisone 200 mg/day for 7 days, followed by 100 mg/day for 4 days, and then 50 mg/day for 3 days (total of 14 days) was used in the CAPE COVID study. If a patient’s respiratory and general status sufficiently improved by day 4, a shorter treatment regimen of Hydrocortisone was used at a dosage of 200 mg/day for 4 days followed by 100 mg/day for 2 days and then 50 mg/day for 2 days (total of 8 days).</td>
<td></td>
</tr>
<tr>
<td>Hydrocortisone</td>
<td>ASHP COVID-19</td>
<td>Dosage</td>
<td>A fixed dosage of IV Hydrocortisone (50 or 100 mg every 6 hours for 7 days) or a shock-dependent regimen of IV hydrocortisone (50 mg every 6 hours for up to 28 days in the presence of clinically evident shock) was used in the REMAP-CAP study.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Dexamethasone randomized, controlled, open-label, multicenter study (NCT04327401; CoDEX):** This trial was conducted to determine whether IV dexamethasone increases the number of ventilator-free days among patients with COVID-19-associated ARDS. The study enrolled adults with COVID-19 and moderate or severe ARDS who were receiving mechanical ventilation from 41 ICUs in Brazil. In the dexamethasone treatment arm, 151 patients were randomized to receive dexamethasone (20 mg IV once daily for 5 days followed by 10 mg IV once daily for another 5 days or until ICU discharge) plus standard care; 148 patients were randomized to receive standard care alone. The primary study end point was ventilator-free days (defined as number of days alive and free from mechanical ventilation) during the first 28 days. Preliminary data analysis indicates that use of IV dexamethasone plus standard care was associated with a higher mean number of ventilator-free days (6.6 days) compared with those receiving standard care alone (4 days). Although there were no significant differences in all-cause mortality at 28 days between the treatment groups, the trial was terminated early after results of the RECOVERY trial became available and, therefore, likely underpowered to determine secondary outcomes such as mortality. Dexamethasone was not associated with an increased risk of adverse effects in this study population of critically ill COVID-19 patients. |

**Note:** The NIH guidelines panel also states that prolonged use of systemic corticosteroids in patients with COVID-19 may increase the risk of reactivation of latent infections (e.g., hepatitis B virus [HBV], herpesvirus, strongyloidiasis, tuberculosis). The risk of reactivation of latent infections following a 10-day course of dexamethasone (6 mg once daily) is not well established. When initiating dexamethasone in patients with COVID-19, appropriate screening and treatment to reduce the risk of *Strongyloides* hyperinfection in those at high risk of strongyloidiasis (e.g., patients from tropical, subtropical, or warm, temperate regions or those engaged in agricultural activities) or fulminant reactivations of HBV should be considered. Dexamethasone in COVID-19 patients who do not require supplemental oxygen. |

The NIH guidelines panel also states that it is not known at this time whether other corticosteroids will have a similar benefit as dexamethasone. However, if dexamethasone is not available, the panel recommends using alternative corticosteroids (e.g., hydrocortisone, methylprednisolone, prednisone) |

IDSA suggests the use of corticosteroids over no corticosteroid therapy in hospitalized patients with severe COVID-19 (i.e., defined as patients with SpO2 ≤94% on room air and those who require supplemental oxygen, mechanical ventilation, or ECMO). These experts suggest the use of dexamethasone 6 mg orally or IV daily for 10 days or until hospital discharge, whichever comes first, or

| Hydrocortisone randomized, double-blind sequential trial (NCT02517489; CAPE COVID): This trial was conducted to evaluate the effect of low-dose hydrocortisone compared with placebo on treatment failure in critically ill patients with COVID-19-related acute respiratory failure. The study enrolled adults with COVID-19-associated acute respiratory failure from 9 ICUs in France. In the hydrocortisone treatment arm, 76 patients received a continuous IV infusion of hydrocortisone at an initial dosage of 200 mg/day for 7 days followed by 100 mg/day for 4 days, and then 50 mg/day for 3 days (total of 14 days; some patients received a shorter regimen); 73 patients received placebo. The primary study end point was treatment failure (defined as death or persistent dependency on mechanical ventilation or high-flow oxygen therapy) on day 21. Treatment failure on day 21 occurred in 42.1% of patients in the hydrocortisone group compared with 50.7% of patients in the placebo group. The difference between the treatment groups was not statistically significant; however, the study was discontinued early after results of the RECOVERY trial were announced and, therefore, likely underpowered to determine a statistically and clinically important difference in the primary outcome.  

Hydrocortisone multicenter, ongoing, international open-label trial using a randomized, embedded multifactorial adaptive platform (NCT02735707; REMAP-CAP):  
This trial randomized patients to multiple interventions within multiple domains. In the COVID-19 corticosteroid domain, adults from 8 countries with suspected or confirmed COVID-19 following admission to an ICU for respiratory or cardiovascular organ support were randomized to receive a fixed 7-day regimen of IV hydrocortisone (50 or 100 mg every 6 hours), a shock-dependent regimen of IV hydrocortisone (50 mg every 6 hours when shock was clinically evident), or no hydrocortisone or other corticosteroid. The primary study end point was organ support-free days (defined as days alive and free of ICU-based respiratory or substitution of equivalent daily dosages of other corticosteroids (e.g., methylprednisolone 32 mg, prednisone 40 mg) if dexamethasone is unavailable. However, IDSA suggests against using corticosteroids in hospitalized patients with COVID-19 without hypoxemia requiring supplemental oxygen.  

The WHO Guideline Development Group strongly recommends the use of systemic corticosteroids (e.g., dexamethasone 6 mg orally or IV daily or hydrocortisone 50 mg IV every 8 hours for 7-10 days) over no systemic corticosteroid therapy for the treatment of patients with severe and/or critical COVID-19, regardless of hospitalization status. This treatment recommendation includes critically ill patients with COVID-19 who could not be hospitalized or receive oxygen supplementation because of resource limitations. This treatment recommendation is less clear for populations under-represented in recent clinical trials (e.g., children, patients with tuberculosis, immunocompromised individuals); however, the risk of not using systemic corticosteroids and depriving such patients of potentially life-saving therapy should be considered. The WHO treatment recommendation does not apply to the following uses of corticosteroids: transdermal or inhaled administration, high-dose or long-term dosage regimens, or prophylaxis.  

Cytokine storm: There is no well-established or evidence-based treatment for cytokine storm in patients with COVID-19. However, some experts suggest that use of more potent immunosuppression with corticosteroids may be beneficial in such patients. These experts suggest higher dosages of corticosteroids (e.g., IV methylprednisolone 60-125 mg every 6 hours for up to 3 days) followed by tapering of the dose when inflammatory markers (e.g., C-reactive protein levels) begin to decrease. |

<td></td>
<td>Prospective meta-analysis of studies using systemic corticosteroids (i.e., dexamethasone, hydrocortisone, or methylprednisolone) from the WHO Rapid Evidence Appraisal for COVID-19 Therapies (REACT) Working Group: This meta-analysis pooled data from 7 randomized clinical trials in 12 countries that evaluated the efficacy of corticosteroids in 1703 critically ill patients with COVID-19. The primary outcome was all-cause mortality up to 30 days after randomization to treatment. Administration of systemic corticosteroids was associated with lower all-cause mortality at 28 days compared with usual care or placebo (222 deaths among 678 patients who received corticosteroids and 425 deaths among 1025 patients who received usual care or placebo). The effect of corticosteroids on reduced mortality was observed in critically ill patients who were and were not receiving mechanical ventilation at randomization and also in patients from the RECOVERY trial who required supplemental oxygen with or without noninvasive ventilation but who were not receiving invasive mechanical ventilation at the time of randomization. The odds ratios for the association between corticosteroids and mortality were similar for dexamethasone and hydrocortisone. The optimal dosage and duration of corticosteroid treatment could not be determined from this analysis; however, there was no evidence suggesting that a</td>

<tr>
<td></td>
<td></td>
<td></td>
<td>Septic shock: The effect of corticosteroids in COVID-19 patients with sepsis or septic shock may be different than the effects seen in those with ARDS. The Surviving Sepsis Campaign and NIH suggest the use of low-dose corticosteroid therapy (e.g., hydrocortisone 200 mg daily as an IV infusion or intermittent doses) over no corticosteroid therapy in adults with COVID-19 and refractory shock. Randomized controlled studies evaluating use of corticosteroids (e.g., hydrocortisone, dexamethasone, methylprednisolone, prednisolone) in septic shock suggest a small, but uncertain mortality reduction. Clinicians considering corticosteroids for such patients with COVID-19 should balance the potential small reduction in mortality with potential effects of prolonged coronavirus shedding. If corticosteroids are prescribed, monitor and treat adverse effects including hyperglycemia, hypernatremia, and hypokalemia. Patients receiving corticosteroid therapy for chronic conditions: NIH states that oral corticosteroids used for the treatment of an underlying condition prior to COVID-19 infection (e.g., primary or secondary adrenal insufficiency, rheumatologic diseases) should not be discontinued. Supplemental or stress dosages of corticosteroids may be indicated on an individual basis in patients with such conditions. Clinicians (injected) in this Evidence Table for recommendations for use of inhaled corticosteroids in COVID-19 patients with asthma or COPD.) Rheumatology experts, including members of the American College of Rheumatology COVID-19 Clinical Guidance Task Force, state that abrupt discontinuance of corticosteroid therapy in patients with rheumatologic diseases should be avoided regardless of COVID-19 exposure or infection status. These experts also state that if indicated,</td>

<td>Higher dosage of corticosteroids was associated with greater benefit than a lower dosage. The authors also concluded that there was no suggestion of an increased risk of serious adverse effects associated with corticosteroid use. &lt;sup&gt;42&lt;/sup&gt;</td>
<td><strong>Methylprednisolone open-label, multicenter, randomized, controlled study (NCT04244591):</strong> This recently completed trial compared use of methylprednisolone in conjunction with standard care in patients with confirmed COVID-19 infection that progressed to acute respiratory failure; results have not yet been posted. &lt;sup&gt;23&lt;/sup&gt;</td>
<td><strong>Retrospective, observational study of systemic corticosteroid use in patients with COVID-19 from a New York hospital (Keller et al):</strong> Data are available for 1806 patients hospitalized with COVID-19 between Mar 11 and Apr 13, 2020. Patients included in the analysis were those treated with systemic corticosteroids (e.g., dexamethasone, hydrocortisone, methylprednisolone, prednisone) within the first 48 hours of hospital admission (140 patients) and those not treated with corticosteroids (1666 patients) as the control group. Treatment and control groups were similar except that corticosteroid-treated patients were more likely to have a history of COPD, asthma, rheumatoid arthritis, or lupus, or to have received corticosteroids in the year prior to admission. Primary goal of the study was to determine whether early systemic corticosteroid treatment was associated with reduced mortality or need for mechanical ventilation. Overall, early use of systemic corticosteroids was not associated with in-hospital mortality or mechanical ventilation. However, there was a significant treatment effect based on C-reactive protein (CRP) levels. Early use of corticosteroids in patients with initial CRP levels of ≥20 mg/dL was associated with a significantly reduced risk of mortality or need for mechanical ventilation (odds ratio: 0.23). Conversely, such treatment in patients with initial CRP levels of &lt;10 mg/dL was associated with a significantly increased risk of mortality or need for mechanical ventilation.</td>
<td>Corticosteroids should be used at the lowest effective dosage to control manifestations, but also acknowledge that higher dosages may be necessary in the context of severe, vital organ-threatening rheumatologic disease even following COVID-19 exposure. &lt;sup&gt;28-30&lt;/sup&gt; Endocrinology experts state that patients with primary or secondary adrenal insufficiency who are receiving prolonged corticosteroid therapy should follow usual steroid “sick day rules” since these individuals may not be able to mount a normal stress response in the event of COVID-19 infection. &lt;sup&gt;19, 26&lt;/sup&gt; If such individuals develop symptoms such as fever and a dry continuous cough, they should immediately double their daily oral corticosteroid dosage and continue with this regimen until the fever subsides. &lt;sup&gt;19&lt;/sup&gt; These guidelines also apply to patients who are receiving prolonged therapy (&gt; 3 months) with corticosteroids for underlying inflammatory conditions, including asthma, allergy, and rheumatoid arthritis. &lt;sup&gt;19&lt;/sup&gt; In such patients whose condition worsens or in those experiencing vomiting or diarrhea, treatment with parenteral corticosteroids may be necessary. &lt;sup&gt;19, 26&lt;/sup&gt; Administration of physiologic stress doses of corticosteroids (e.g., IV hydrocortisone 50-100 mg 3 times daily) and not pharmacologic doses should be considered in all cases to avoid potentially fatal adrenal failure. &lt;sup&gt;19, 20&lt;/sup&gt; Additional study is needed to determine the optimum corticosteroid stress dosage regimens in patients with COVID-19. &lt;sup&gt;26, 27&lt;/sup&gt; There is some evidence suggesting that continuous IV infusion of hydrocortisone (following an initial IV bolus dose) may provide more stable circulating cortisol concentrations in patients with adrenal insufficiency and reduce the potentially harmful effects of peak and trough concentrations of cortisol on the immune system. &lt;sup&gt;26, 27&lt;/sup&gt; <strong>Pregnancy considerations:</strong> For pregnant women with COVID-19, the NIH...</td>

<td></td>
<td></td>
<td></td>
<td>ventilation (odds ratio: 2.64). The authors state that these findings suggest that appropriate selection of COVID-19 patients for systemic corticosteroid treatment is critical to maximize the likelihood of benefit and minimize the risk of harm. <strong>Note:</strong> The limitations of the observational study design should be considered when interpreting these results. Corticosteroid dosages used in patients included in this study not provided. Further study is needed to determine the role of CRP levels in guiding the use of corticosteroid treatment in patients with COVID-19. (^{36})</td>
<td></td>
<td>COVID-19 Treatment Guidelines Panel states that a short course of corticosteroids that cross the placenta (i.e., betamethasone, dexamethasone) is routinely used for fetal benefit (e.g., to hasten fetal lung maturity). Given the potential benefit of decreased maternal mortality and the low risk of fetal adverse effects for this short course of corticosteroid therapy, the panel recommends the use of dexamethasone in pregnant women with COVID-19 who are receiving mechanical ventilation or in those who require supplemental oxygen but are not on mechanical ventilation. (^{24})</td>

<td><strong>Nitric oxide (inhaled)</strong></td>
<td>48:48 Vasodilating Agent</td>
<td>Selective pulmonary vasodilator with bronchodilatory and vasodilatory effects in addition to other systemic effects mediated through cGMP-dependent or independent mechanisms; may be useful for supportive treatment of acute respiratory distress syndrome (ARDS), a complication of COVID-19. Also has been shown to have antiviral effects.</td>
<td>Randomized controlled studies of inhaled nitric oxide in ARDS patients have generally demonstrated modest improvements in oxygenation, but no effect on mortality and possible harm (e.g., renal impairment). Experience with inhaled nitric oxide specifically in COVID-19 patients is limited. In a published case report, improvement in PaO₂ and oxygen saturations was observed after administration of inhaled nitric oxide in a 12-year-old patient with COVID-19 and severe thrombocytopenia who required mechanical ventilation; the dose of nitric oxide was not reported and the patient was in the Chen et al. study in severe SARS patients, inhaled nitric oxide therapy was given for ≥3 days (30 ppm on day 1, followed by 20 and 10 ppm on days 2 and 3, respectively, then weaned on day 4; therapy was resumed at 10 ppm if deteriorating oxygenation occurred). Various dosing protocols using different methods of delivery are being evaluated in ongoing studies in COVID-19 patients.</td>
<td>In the Chen et al. study in severe SARS patients, inhaled nitric oxide therapy was given for ≥3 days (30 ppm on day 1, followed by 20 and 10 ppm on days 2 and 3, respectively, then weaned on day 4; therapy was resumed at 10 ppm if deteriorating oxygenation occurred). Various dosing protocols using different methods of delivery are being evaluated in ongoing studies in COVID-19 patients.</td>
<td>The NIH COVID-19 Treatment Guidelines Panel and the Surviving Sepsis Campaign recommend against the routine use of inhaled nitric oxide in mechanically ventilated adults with COVID-19 and ARDS. These experts state that a trial of inhaled pulmonary vasodilator may be considered as rescue therapy in mechanically ventilated adults with COVID-19, severe ARDS, and hypoxemia; however, if no rapid improvement in oxygenation is observed, the patient should be tapered off treatment.</td>

<tr>
<td>Sarilumab (Kevzara&lt;sup&gt;®&lt;/sup&gt;) Updated 9/10/20</td>
<td>92:36 Disease-modifying Anti-rheumatic Drug</td>
<td>Recombinant humanized monoclonal antibody specific for the interleukin-6 (IL-6) receptor; IL-6 is a proinflammatory cytokine. Sarilumab may potentially combat cytokine release syndrome (CRS) and pulmonary symptoms in severely ill patients&lt;sup&gt;1,2,5,7&lt;/sup&gt;</td>
<td>Preliminary unpublished data from randomized clinical trials have not demonstrated efficacy in treatment of patients with COVID-19&lt;sup&gt;7,11,12&lt;/sup&gt; However, based on encouraging results in China with a similar drug, tocilizumab, a large, U.S.-based, phase 2/3, randomized, double-blind, placebo-controlled, adaptively designed study (NCT04315298) evaluating efficacy and safety of sarilumab in patients hospitalized with severe COVID-19 was performed&lt;sup&gt;3,4,7,9,10,12&lt;/sup&gt; Patients in this study were randomized (2:2:1) to receive sarilumab 400 mg, sarilumab 200 mg, or placebo. Randomization was stratified by severity of illness (e.g., severe, critical, multisystem organ dysfunction) and use of systemic corticosteroids&lt;sup&gt;7,12&lt;/sup&gt;. In the phase 2 part of the study, sarilumab at both doses reduced C-reactive protein (CRP) levels. The primary efficacy outcome measure in phase 3 was the change on a 7-point scale; this phase was modified to focus on the 400-mg dose of sarilumab in the critically ill patient group. During the course of the trial, there were many amendments that increased the sample size and modified the dosing strategies, and multiple interim analyses were performed. The results did not demonstrate a clinical benefit of sarilumab for any of the disease severity subgroups or dosing strategies studied&lt;sup&gt;7,9,12&lt;/sup&gt;. A second manufacturer-sponsored phase 3 clinical trial was conducted in countries outside the U.S. (Argentina, Brazil, Canada, Chile, France, Germany, Israel, Italy, Japan, Spain) in 420 severely or critically ill patients hospitalized with COVID-19 did not meet its primary endpoint and key secondary endpoint when sarilumab was compared with placebo in addition to usual hospital care. Although not statistically significant, trends were observed toward a decrease in duration of hospital stay, an acceleration in time to improved clinical outcomes, reduced mortality in the critically ill patient group not seen in the severely ill group, and a shortened time to discharge&lt;sup&gt;1,11&lt;/sup&gt;.</td>
<td>Large US-based controlled study (NCT04315298): Dosage of 400 mg IV as a single dose or multiple doses (based on protocol criteria); the lower-dose (200-mg) treatment arm was discontinued following a preliminary analysis of study results&lt;sup&gt;9,10&lt;/sup&gt; (see Trials or Clinical Experience) Note: IV formulation not commercially available in the U.S., but was studied in the above-mentioned clinical trial. The sub-Q formulation is not FDA-labeled to treat cytokine release syndrome (CRS) in the U.S.&lt;sup&gt;7&lt;/sup&gt;</td>

| Siltuximab (Sylvant®) | 10:00 Antineoplastic agents | Recombinant chimeric monoclonal antibody specific for the interleukin-6 (IL-6) receptor; may potentially combat cytokine release syndrome (CRS) symptoms (e.g., fever, organ failure, death) in severely ill patients | **Italian case series (Benucci et al.)** describes 8 patients hospitalized with COVID-19 pneumonia at one hospital in Florence treated with sarilumab (initial 400-mg IV dose followed by 200-mg IV doses after 48 and 96 hours) in addition to standard therapy (hydroxychloroquine, azithromycin, darunavir, cobicistat, enoxaparin). Treatment was started within 24 hours of hospitalization. Sarilumab was used in these patients because of a lack of tocilizumab at this institution. Seven of the patients demonstrated an improvement in oxygenation and lung echo score and were discharged within 14 days; the remaining patient died in 13 days.  

**Multiple clinical trials to evaluate sarilumab for treatment of COVID-19** are registered at clinicaltrials.gov.  

**For compassionate use access or investigator-sponsored clinical studies, contact the manufacturer (Sanofi Genzyme) for further information (1-800-633-1610).**  

In the SISCO study in Italy, patients received an initial dose of siltuximab 11 mg/kg by IV infusion over 1 hour; a second dose could be administered at the physician’s discretion.  

Other clinical studies under way are evaluating a single siltuximab dose of 11 mg/kg by IV infusion.  

Efficacy and safety of siltuximab in the treatment of COVID-19 not established.

Zinc

Updated 8/6/20

Despite some anecdotal claims in the media that zinc is effective in treating COVID-19, 6 unclear whether zinc supplementation is beneficial in the prophylaxis and/or treatment of COVID-19; further study is needed 1, 3, 6

NIH COVID-19 Treatment Guidelines Panel states that there are insufficient clinical data to recommend either for or against use of zinc in the treatment of COVID-19 9

NIH COVID-19 Treatment Guidelines Panel recommends against using zinc supplementation above the RDA for the prevention of COVID-19, except in a clinical trial 9

Zinc concentrations are difficult to measure accurately since it is distributed as a component of various proteins and amino acids 9

Adverse effects may include nausea (possibly dose dependent), vomiting, and changes in taste 1, 6, 7, 8

Updated 10-1-20. The current version of this document can be found on the ASHP COVID-19 Resource Center. This work is licensed under a Creative Commons Attribution-NonCommercial 4.0 International License.

|        |            |           | Matched to 30,759 controls based on sex, age, and place of residence. Information about use of selected drugs and clinical profiles was obtained from regional healthcare databases. Use of ACE inhibitors or ARBs was more frequent in patients with COVID-19 than among controls because of their higher prevalence of cardiovascular disease. Percentage of patients receiving ACE inhibitors was 23.9% for case pts and 21.4% for controls. Percentage of patients receiving ARBs was 22.2% and 19.2% for case and control pts, respectively. The authors concluded that there was no evidence that treatment with ACE inhibitors or ARBs significantly affected the risk of COVID-19 or altered the course of infection or resulted in more severe disease.  

Large, multinational, retrospective study analyzed outcome data for hospitalized pts with confirmed COVID-19 to evaluate the relationship between cardiovascular disease and preexisting treatment with ACE inhibitors or ARBs with COVID-19 (Mehra et al; now retracted): Original publication included multinational data for 8910 pts hospitalized with COVID-19 between Dec 20, 2019 and Mar 15, 2020 that were obtained from a global healthcare data collaborative. The authors concluded that those data confirmed previous observations suggesting that underlying cardiovascular disease is independently associated with an increased risk of death in hospitalized pts with COVID-19. They also stated that they were not able to confirm previous concerns regarding a potential harmful association of ACE inhibitors or ARBs with in-hospital mortality.  

Note: This published study has now been retracted by the publisher at the request of the original authors. Concerns were raised with respect to the veracity of the data and analyses that were the basis of the authors’ conclusions.  

Clinical trials underway (losartan): Initiation of losartan in adults with COVID-19 requiring hospitalization; primary outcome measure: sequential organ failure assessment (SOFA) respiratory score. (NCT04312009). | | |

<td>Anti-coagulants</td>
<td><strong>Initiation of the drug in adults with COVID-19 not requiring hospitalization; primary outcome measure: treatment failure resulting in hospital admission (NCT04311177).</strong> Other clinical trials have been initiated in various countries to evaluate the effect of continuing or discontinuing treatment with ACE inhibitors or ARBs on clinical outcomes in patients with COVID-19, including the following trials registered at clinicaltrials.gov: NCT04329195, NCT04331574, NCT04338009, NCT04351581, NCT04353596, NCT04357535.</td>
<td>See Comments column for available dosage-related information.</td>
<td>Additional study is needed to understand the anticoagulant needs of COVID-19 patients. WHO recommends pharmacologic prophylaxis (e.g., LMWH) according to local and international standards for prevention of VTE in adults and adolescents hospitalized with COVID-19 unless contraindicated. The NIH COVID-19 Treatment Guidelines Panel recommends VTE prophylaxis according to the usual standard of care in all hospitalized adults with COVID-19 unless contraindicated. Several organizations have published interim guidance for the management of COVID-19-associated coagulopathy. The International Society for Thrombosis and Haemostasis and American Society of Hematology recommend that all hospitalized COVID-19 patients receive prophylactic-dose LMWH unless contraindicated (e.g., active bleeding, severe thrombocytopenia, fibrinogen &lt;0.5 g/L).</td>
</tr>
</tbody>
</table>

Patients with COVID-19, particularly those with severe disease, may develop a hypercoagulable state, which has been associated with poor outcomes (e.g., progressive respiratory failure, acute respiratory distress syndrome [ARDS], death). Most common pattern of coagulopathy in hospitalized COVID-19 patients is characterized by elevated D-dimer levels, high fibrinogen levels, minimal prolongation of aPTT and/or PT, and mild thrombocytopenia; microvascular and macrovascular thrombosis also have been reported. In addition, high rates of VTE have been observed in critically ill patients with COVID-19. Pathogenesis of COVID-19-related coagulopathy not completely known, but may be related to an... |

<td>uncontrolled immuno-thrombotic response to viral infection.</td>
<td>from the same health system, use of prophylactic or therapeutic anticoagulation was associated with lower in-hospital mortality compared with no anticoagulant therapy (adjusted hazard reductions of 50 and 47%, respectively). In addition, the risk of intubation was about 30% lower in patients treated with either prophylactic or therapeutic anticoagulation. Overall bleeding rates were low, but higher in the therapeutic anticoagulation group (3%) compared with the prophylactic anticoagulation (1.7%) and no anticoagulation (1.9%) groups. Among 26 autopsies performed in this cohort of patients, 42% had evidence of thromboembolic disease not otherwise suspected premortem; the majority of these patients were not treated with therapeutic anticoagulation. Because a variety of anticoagulants were used in these patients including LMWH, UFH, and direct oral anticoagulants, no conclusions can be drawn regarding optimal choice of anticoagulant. The study is limited by its observational design; randomized controlled studies are needed to confirm findings.</td>

<td>Additional clinical trials have been initiated or currently are underway to evaluate anticoagulant strategies in patients with COVID-19, including the following: NCT04512079 (FREEDOM), NCT04406389 (IMPACT), NCT04362085,</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>LMWH or UFH may be preferred over oral anticoagulants in critically ill hospitalized patients with COVID-19 because of their shorter half-lives, ability to be administered parenterally, and fewer drug-drug interactions. Patient-specific factors (e.g., renal function) and practical concerns (e.g., need for frequent monitoring, convenience of administration, risk of medical staff exposure) may influence choice of anticoagulant. Because of the severity of coagulopathy in critically ill COVID-19 patients and reports of high rates of VTE despite routine prophylaxis, some clinicians have used (or suggested the use of) higher prophylactic doses or even therapeutic doses of anticoagulants to prevent thromboembolic complications in such patients; however, prospective studies are needed to evaluate these approaches. Pending additional data, use of higher-intensity nonstandard VTE prophylaxis or therapeutic-dose anticoagulation should ideally be done in the context of a clinical trial. Based on expert opinion, the Anticoagulation Forum suggests increased doses of VTE prophylaxis (e.g., enoxaparin 40 mg BID, enoxaparin 0.5 mg/kg BID, heparin 7500 units sub-Q 3 times daily, or low-intensity heparin infusion) for critically ill patients (e.g., in the ICU) with confirmed or suspected COVID-19. NIH and other experts state that the current data are insufficient to recommend for or against the use of therapeutic anticoagulants in COVID-19 patients in the absence of confirmed or suspected thrombosis. The efficacy of intermediate or full-dose therapeutic anticoagulation for critically ill COVID-19 patients without documented VTE is currently being evaluated. Patients who are already on anticoagulant therapy for an existing condition (e.g., VTE, atrial fibrillation) should</td>

Drug(s): convalescent plasma

AHFS Class: Rationale

Trials or Clinical Experience: but not in the small cohort of intubated patients (hazard ratio: 1.24). No significant transfusion-related morbidity or mortality was observed in patients receiving convalescent plasma.32

Uncontrolled pilot study in China (Duan et al): 10 adults with severe COVID-19 received a single transfusion of COVID-19 convalescent plasma (containing SARS-CoV-2 neutralizing antibody titers of 1:640 or greater) with standard care; all patients received antiviral therapy (e.g., umifenovir [Arbidol®], ribavirin, oseltamivir, peramivir, interferon α) and 6 patients also received methylprednisolone. The median time from onset of symptoms to transfusion of convalescent plasma was 16.5 days. COVID-19 symptoms (fever, cough, shortness of breath, chest pain) improved in all patients within 1-3 days after the transfusion and all patients showed radiologic improvement in pulmonary lesions. Titers of neutralizing antibody increased in 5 patients after the transfusion, but remained the same in 4 patients. Prior to the transfusion, RT-PCR tests for SARS-CoV-2 RNA were positive in 7 patients and negative in 3 patients; after transfusion, SARS-CoV-2 RNA was undetectable in 3 patients on day 2, 3 patients on day 3, and 1 patient on day 6. 39

Uncontrolled case series in China (Shen et al): 5 critically ill adults with rapidly progressing severe COVID-19 and acute respiratory distress syndrome (ARDS) requiring mechanical ventilation who had high viral loads despite antiviral treatment received 2 transfusions of COVID-19 convalescent plasma (containing SARS-CoV-2 neutralizing antibody end point dilution titers of 80-480 depending on the donor); patients continued to receive antiviral treatments (e.g., LPV/RTV, favipiravir, umifenovir [Arbidol®], darunavir, interferon α-1b) and methylprednisolone. Patients received the convalescent plasma transfusions 10-22 days after hospital admission. Following the transfusions, body temperature normalized within 3 days in 4/5 patients, sequential organ failure assessment (SOFA) scores improved in all patients (decreased from the significant known and potential risks and benefits of emergency use of COVID-19 convalescent plasma.37, 38 Healthcare facilities and healthcare providers administering COVID-19 convalescent plasma must comply with certain mandatory record keeping and reporting requirements (including adverse event reporting). 38 Consult the EUA,37 EUA fact sheet for healthcare providers,36 and EUA fact sheet for patients and parents/caregivers41 for additional information.

The EUA states that COVID-19 convalescent plasma should not be considered a new standard of care for the treatment of patients with COVID-19. FDA states that adequate and well-controlled randomized trials remain necessary to determine optimal product attributes and to identify appropriate subpopulations for its use and that ongoing clinical trials of COVID-19 convalescent plasma should not be amended based on issuance of the EUA. 37

The NIH COVID-19 Treatment Guidelines Panel states that there are insufficient data to recommend for or against the use of convalescent plasma in patients with COVID-19 and that COVID-19 convalescent plasma should not be considered a standard of care for the treatment of patients with COVID-19. 25

The Surviving Sepsis Campaign COVID-19 subcommittee suggests that convalescent plasma not be used routinely in critically ill adults with COVID-19 because efficacy and safety not established and uncertainty surrounding optimal preparation of convalescent plasma. 10

Appropriate criteria for selection of patients to receive investigational COVID-19 convalescent plasma, optimal time during the course of the disease to receive such therapy, and appropriate dosage (e.g., volume, number of doses)

---|---|---|---|---|---

Convalescent plasma in addition to multiple other treatments (e.g., antivirals, anti-inflammatory agents). The median time from symptom onset to plasma transfusion was 10 days and 24/25 patients received a single transfusion. Convalescent plasma was well tolerated and no transfusion-related adverse events were reported. At day 7 post-transfusion, 9 patients (36%) had clinical improvement (defined as at least a 1-point improvement based on a 6-point ordinal scale); by day 14 post-transfusion, 19 patients (76%) had clinical improvement or were discharged. The contribution of convalescent plasma to clinical improvement in these patients is unclear since there was no control group and patients also received other treatments.

**Cochrane systematic review:** Analysis of 20 published studies (1 RCT, 3 controlled non-randomized studies of interventions [NRSIs], 16 non-controlled NRSIs) evaluating convalescent plasma in adults with COVID-19 (total of 5443 study participants, of whom 5211 received COVID-19 convalescent plasma) found very low confidence in the efficacy and safety of this treatment approach. There was a high risk of bias within and across the studies and great variability in terms of study design, donor and recipient characteristics, and other previous or concurrent treatments.

**Systematic review (Joyner et al; non-peer-reviewed):** Analysis of pooled data (total of 804 COVID-19 patient outcomes) from 12 studies (3 RCT, 5 matched-control, 4 case series) evaluating convalescent plasma in hospitalized adults with severe or life-threatening COVID-19 found evidence favoring efficacy of this therapeutic approach. The risk of death was substantially reduced in hospitalized COVID-19 patients transfused with convalescent plasma compared to matched patients receiving standard therapy (OR: 0.43, p <0.001). **Note:** There were several limitations to this analysis including aggregating mortality data across study populations that varied by dose and timing of convalescent plasma administration, geographic region, and duration of follow-up.

Decision to use COVID-19 convalescent plasma in patients <18 years of age should be based on an individualized assessment of risks and benefits.

FDA issued a guidance for industry to provide recommendations to healthcare providers and investigators regarding administration and study of investigational COVID-19 convalescent plasma. This guidance document includes recommendations regarding pathways for access to COVID-19 convalescent plasma, collection of such plasma (including donor eligibility and qualifications), product labeling, and record-keeping.

**Additional pathways (outside of the EUA) for administering or studying the use of investigational COVID-19 convalescent plasma:**

1. **Clinical Trials:** Requests to study use of COVID-19 convalescent plasma should be submitted to FDA under the traditional investigational new drug (IND) regulatory pathway.

2. **Expanded Access IND:** FDA is accepting requests for expanded access INDs for use of COVID-19 convalescent plasma in patients with serious or immediately life-threatening COVID-19 who are not eligible or are unable to participate in randomized clinical trials. Consult the FDA guidance document for specific information on applying for an expanded access IND for more than a single patient.

3. **Single Patient Emergency IND (eIND):** Licensed physicians seeking to administer COVID-19 convalescent plasma to individual patients with serious or life-threatening disease may request an eIND from the FDA. Consult the FDA guidance document for specific information on applying for an eIND.

**Donor eligibility:** FDA guidance suggests that COVID-19 convalescent plasma be collected from individuals with laboratory-confirmed evidence of

|         |            |           | **Open-label, randomized, controlled study in Netherlands (Gharbharan et al; Con-COVID study):** Preliminary (non-peer-reviewed) data from a study of 86 hospitalized adults with COVID-19 found no significant difference in mortality, duration of hospital stay, or disease severity on day 15 in patients treated with convalescent plasma (300 mL of convalescent plasma containing anti-SARS-CoV-2 neutralizing antibody titers of ≥1:80) compared with standard of care. **Note:** Anti-SARS-CoV-2 antibodies were detected at baseline in 53/66 patients who had been symptomatic for 10 days prior to study enrollment. Neutralizing antibodies were detected in 44/56 (79%) patients tested with median titers comparable to the donors (1:160). These findings raised concerns about the potential benefit of convalescent plasma in the study population and the study was terminated.  
**Open-label, randomized, controlled study in China (Li et al):** Results of this study in 103 adults with severe or life-threatening COVID-19 found no significant difference in time to clinical improvement within 28 days, mortality, or time to hospital discharge in patients treated with convalescent plasma (containing a high titer of antibody to SARS-CoV-2) plus standard of care compared with standard of care alone. Convalescent plasma therapy was well tolerated by the majority of patients; 2 cases of transfusion-associated adverse events were reported. There was a signal of possible benefit in the subgroup of patients with severe COVID-19 disease. However, the study had several limitations that preclude any definite conclusions, including the possibility of being underpowered as the result of early termination because of the lack of available patients. In addition, most patients received convalescent plasma treatment at least 14 days after symptom onset and it is unclear whether earlier treatment would have resulted in greater benefit.  
**Open-label, single-arm, phase 2 study (Ibrahim et al):** Preliminary (non-peer-reviewed) data from a study of 38 severely ill COVID-19 infection and complete resolution of symptoms for at least 14 days before donation (a negative result for COVID-19 by a diagnostic test is not necessary to qualify the donor). Antibody titers in donor plasma: According to the EUA, COVID-19 convalescent plasma with an S/Co value of ≥12 (as determined by the Ortho VITROS SARS-CoV-2 IgG test) qualifies as high-titer COVID-19 convalescent plasma. Low-titer COVID-19 convalescent plasma must be labeled accordingly and may be considered for use following assessment of the potential benefits and risks of convalescent plasma therapy for the individual patient. | COVID-19 infection and complete resolution of symptoms for at least 14 days before donation (a negative result for COVID-19 by a diagnostic test is not necessary to qualify the donor). difference in composite outcome of death, mechanical ventilation, or prolonged hospital admission (>14 days) in patients who received convalescent plasma (up to two transfusions of 200 mL) immediately following hospital admission compared with those who received convalescent plasma at clinical deterioration. Two patients developed severe respiratory deterioration within 6 hours after transfusion of convalescent plasma and were categorized as possible transfusion-associated acute lung injury (TRALI) type II. 47

**Expanded access IND protocol (Joyner et al):** Analysis of 35,322 adults hospitalized with laboratory-confirmed SARS-CoV-2 infection who had or were considered at high risk of progression to severe or life-threatening COVID-19 who participated in a US FDA Expanded Access Program (NCT04338360) suggests that 7- and 30-day mortality rates are substantially reduced in patients transfused with convalescent plasma within 3 days of COVID-19 diagnosis. Patients received at least one unit (approximately 200 mL) of ABO-compatible COVID-19 convalescent plasma IV according to institutional transfusion guidelines. A statistically significant difference in crude 7-day mortality was observed between patients transfused with convalescent plasma within 3 days of COVID-19 diagnosis compared with those transfused with convalescent plasma 4 or more days after COVID-19 diagnosis (8.7 vs 11.9%). Similar findings were observed for 30-day mortality rate (21.6 vs 26.7%). A reduction in 7- and 30-day mortality rate also was observed in patients transfused with convalescent plasma containing higher IgG antibody levels (>18.45 signal-to-cut-off [S/Co] ratio) compared with those transfused with convalescent plasma containing IgG antibody levels ≤18.45 S/Co. 36 Analysis of key safety indicators in 20,000 adults who participated in this Expanded Access Program suggests that IV transfusion of convalescent plasma is safe in hospitalized patients with COVID-19. Within the first 4 hours after transfusion, 146 serious adverse events (i.e., transfusion-associated circulatory overload,

<td></td>
<td>Open-label, prospective study (Madariaga et al; non-peer-reviewed): The relationship between clinical and serologic parameters in a group of COVID-19 convalescent plasma donors and antibody responses in recipients of convalescent plasma was evaluated. SARS-CoV-2 anti-receptor binding domain (anti-RBD) and anti-spike antibody titers ranged from 0 to 1:3892 and 0 to 1:3289, respectively, in 103 convalescent plasma donors; mean duration of COVID-19 symptoms in the plasma donors was 11.9 days and mean interval between symptom onset and convalescent plasma donation was 45.1 days; predictors of higher antibody titers in the donors included advanced age, fever, absence of myalgia, fatigue, ABO blood type, and previous hospitalization. In this study, 10 hospitalized adults with severe or life-threatening COVID-19 received 1 or 2 units (approximately 300 mL per unit administered IV over 4 hours) of ABO-compatible COVID-19 convalescent plasma (units had SARS-CoV-2 anti-RBD antibody titers of 1:73 to 1:3892 and anti-spike antibody titers of 1:69 to 1:2921) within 21 days after symptom onset and 80% of these patients had a significant increase in SARS-CoV-2 anti-spike and anti-RBD antibody titer by post-transfusion day 3 and were discharged after clinical improvement; antibody titers in the convalescent plasma recipients were independent of donor antibody titer. SARS-CoV-2 antibody titers</td>

<td>Famotidine</td>
<td>56.28.12</td>
<td>Histamine H₂ Antagonists</td>
<td>Currently no known published prospective clinical trial evidence supporting efficacy or safety for treatment of COVID-19. Randomized, double-blind, placebo-controlled, comparative trial (NCT04370262) is evaluating high-dose IV famotidine plus standard care vs placebo plus standard care in hospitalized adults with moderate to severe COVID-19; targeted enrollment is at least 942 patients. Other randomized clinical trials also evaluating famotidine for treatment of COVID-19, including NCT04504240. Retrospective cohort study of 10 outpatients self-medicating with high-dose famotidine following onset of symptoms consistent with COVID-19: No hospitalizations reported; all patients reported symptomatic improvement within 1-2 days, with continued improvement over 14-day period. Patients were symptomatic for 2-26 days before initiating famotidine. Total of 7 patients had PCR-confirmed COVID-19,</td>
<td>Dosage in NCT04370262: Famotidine is being given IV in 120-mg doses (proposed total daily dosage of 360 mg) for maximum of 14 days or until hospital discharge, whichever comes first. Proposed daily dosage in NCT04370262 is 9 times the usual manufacturer-recommended IV adult dosage; the study excludes patients with creatinine clearance (Clₖ) ≤50 mL/minute, including dialysis patients; renally impaired patients may be at increased risk of adverse CNS effects since drug half-life is closely related to Clₖ.</td>
<td>Safety and efficacy for treatment of COVID-19 not established. IDSA suggests against using famotidine for the sole purpose of treating COVID-19 in hospitalized patients with severe COVID-19 outside of the context of a clinical trial.</td>

mediating clinical manifestations of COVID-19 has been postulated; it is further postulated that the principal action of famotidine in COVID-19 may relate to activity at H₂ receptors. Anecdotal observations: Observations based on retrospective medical record review indicated that many Chinese COVID-19 survivors had received famotidine for chronic heartburn; mortality rate appeared to be lower in hospitalized COVID-19 patients receiving famotidine than in patients not receiving the drug (14 vs 27%); observations did not control for possible confounding (e.g., socioeconomic) factors. Retrospective matched cohort study of COVID-19 patients hospitalized, but not requiring intubation within the first 48 hrs, at a single New York medical center indicated that the risk for the composite outcome of death or intubation was reduced (mainly due to difference in mortality) in patients who received famotidine within 24 hours of hospital admission (n = 84) vs those who did not receive the drug (n = 1536); overall, 21% of patients met the composite outcome (8.8% were intubated and 15% died); the finding appeared to be specific to the H₂ antagonist and to COVID-19, as the investigators reported observing no protective effect with proton-pump inhibitors or in non-COVID-19 patients. Home use of famotidine was documented on admission in 15% of patients who received the drug in hospital vs 1% of those who did not; 28% of all famotidine doses were IV; 47% of doses were 20 mg, 35% were 40 mg, and 17% were 10 mg; the median duration of use was 5.8 days, and the total median dose was 136 mg (63–233 mg). Retrospective, matched, single-center, observational study in hospitalized patients with RT-PCR-confirmed COVID-19: In-hospital mortality (14.5 vs 26%) and the combined end point of death or intubation (7.2 vs 13.8%) were reduced in patients who received famotidine (n = 83) compared with a propensity score-matched...

<td>HMG-CoA Reductase Inhibitors (statins)</td>
<td>24:06 Antilipemic Agents</td>
<td>In addition to lipid-lowering effects, statins have anti-inflammatory and immunomodulatory effects, which may prevent acute lung injury.</td>
<td>Data from randomized controlled trials are lacking on the use of statins in patients with COVID-19. <strong>Retrospective cohort studies in various settings have indicated potential beneficial effects of statin treatment on disease severity, mortality, and/or recovery time in patients with COVID-19.</strong> Meta-analyses conducted using data from retrospective studies have conflicting results. In a retrospective cohort study in 13,981 patients in China hospitalized with COVID-19, statin use during hospitalization was associated with higher rates of intubation and mortality. <strong>Note:</strong> Comparisons were limited to published outcome data from other locales for patients receiving “standard-of-care” regimens.</td>
<td></td>
<td>NIH COVID-19 Treatment Guidelines Panel states patients who are receiving a statin for the treatment or prevention of cardiovascular disease should continue statin therapy. The panel recommends against use of statins for the treatment of COVID-19 except in the context of a clinical trial. Patients with cardiovascular disease are at an increased risk of serious COVID-19 infections.</td>

|          |            |           | associated with lower risk of mortality. The 28-day all-cause mortality was 22% lower in patients who received statins during hospitalization compared with patients who did not receive statins. Among propensity-score-matched patients (861 patients in the statin group vs. 3444 matched patients in the no-statin group), the risk of 28-day all-cause mortality was 42% lower in patients who received statins during hospitalization compared with those who did not receive statins. In addition, lower incidence of invasive mechanical ventilation was observed in the statin-treated patients. The authors note that patients in the statin group were older and had a higher prevalence of comorbidities and more severe symptoms at baseline; matched non-statin patients therefore had more severe baseline symptoms and comorbidities than unmatched patients, which could account for the increased mortality in the non-statin group after propensity score matching.  
In a retrospective cohort study in 154 nursing home residents in Belgium with clinically suspected COVID-19 and/or positive PCR test for SARS-CoV-2, statin use was associated with absence of symptoms (i.e., asymptomatic infection) in this cohort; 45% of the 31 patients receiving statin therapy remained asymptomatic compared with 22% of the 123 patients not receiving statins.  
**In a retrospective cohort study in 170 patients hospitalized for COVID-19 at a single US center, statin use prior to admission was associated with reduced risk of developing severe disease and, among those without severe disease, faster time to recovery. In this study, 27% of pts reported using statins within 30 days prior to hospitalization for COVID-19. Statin use was associated with a 71% lower risk of severe outcome (i.e., death or ICU admission). In addition, rate of recovery in patients without severe disease was higher (hazard ratio for recovery: 2.69) and median time to recovery was shorter for those who received statins. The beneficial effect in patients with active COVID-19 who may develop severe rhabdomyolysis, it may be advisable to withhold statin therapy for a short period of time.**  
Most statins are substrates for the CYP450 system; potential for drug interactions.  
Clinicians should ensure that their high-risk primary prevention (for ASCVD) patients are on guideline-directed statin therapy.  |

<td></td>
<td></td>
<td>of statin use on reduction of severe outcomes in patients with COVID-19 was greater than that observed in a large control cohort of COVID-19-negative patients. 12 <strong>In another retrospective study of 249 patients hospitalized with COVID-19 at multiple US centers, statin use prior to hospitalization was associated with lower risk of invasive mechanical ventilation in some models, but there was no substantial association between statin use and in-hospital death or ICU admission.</strong> 16 <strong>In a retrospective cohort study in 87 patients admitted to the ICU with COVID-19 at a single US center, treatment with atorvastatin (40 mg daily) was associated with a reduced risk of death (adjusted hazard ratio: 0.38).</strong> 13 <strong>Preliminary findings from a meta-analysis (Kow &amp; Hasan) of 4 cohort or case-control studies which included a total of 8990 patients with COVID-19 suggest that statin use is associated with a 30% reduction in risk of severe or fatal outcome in patients with COVID-19.</strong> 14 However, another meta-analysis of 9 cohort or case-control studies (Hariyanto &amp; Kurniawan) did not find an association between statin use and improved severity or mortality outcomes in patients with COVID-19. This meta-analysis included a total of 3449 pts with COVID-19 and included 2 of the same studies used in the Kow &amp; Hasan analysis. 15 Preliminary findings have shown mixed results with other respiratory illnesses; some observational studies suggest statin therapy is associated with a reduction in various cardiovascular outcomes and possibly mortality in patients hospitalized with influenza and/or pneumonia. 3-6 Clinical trials evaluating statin use in COVID-19: Multiple trials registered at clinicaltrials.gov (some listed below): 9 NCT04333407 NCT04343001 NCT04348695 NCT04426084 NCT0440727 (STACOV)</td>

<td>Immune Globulin</td>
<td>80:04</td>
<td>Immune Globulin</td>
<td>SARS Experience: IGIV has been used in the treatment of SARS. Benefits were unclear because of patient comorbidities, differences in stage of illness, and effect of other treatments; IGIV may have contributed to hypercoagulable state and thrombotic complications in some patients. Open-label, prospective, randomized, controlled study in the US (Sakoulas et al; NCT04411667): Preliminary (non-peer-reviewed) data from a study of 33 adults with COVID-19 and moderate to severe hypoxia (defined as SpO2 ≤ 96% requiring ≥ 4 liters O2 by nasal cannula) but not on mechanical ventilation found that IGIV significantly improved hypoxia and reduced hospital length of stay and progression to mechanical ventilation in patients with alveolar-arterial (A-a) gradient ≤ 200 mm Hg treated with IGIV (Octagam® 10% 0.5 g/kg daily for 3 days) plus standard of care compared with standard of care alone. All 16 patients in the IGIV group received premedication with methylprednisolone (40 mg IV) prior to each IGIV dose and 5 of these patients received additional glucocorticoid therapy; 10/17 patients in the standard of care group received some glucocorticoid therapy. COVID-19 case reports in China (Cao et al): Treatment with IGIV at the early stage of clinical deterioration was reported to provide some clinical benefit in 3 adults with severe COVID-19; 2 patients also received antivirals and 1 patient also received short-term steroid treatment. Patients were afebrile within 1-2 days and breathing difficulties gradually improved within 3-5 days of IGIV administration. COVID-19 clinical experience in China: IGIV has been used as an adjunct in the treatment of COVID-19 and has been mentioned in Chinese guidelines as a possible treatment option for severe and critically ill children with COVID-19. Multicenter retrospective study in China: Among a cohort of 325 patients with severe or critical COVID-19 disease, no difference</td>
<td>IGIV dosage of 0.3-0.5 g/kg daily for 3-5 days has been used or is being investigated in patients with COVID-19. Role of commercially available immune globulin (IGIV, IVIG, γ-globulin) and investigational SARS-CoV-2 immune globulin in the treatment of COVID-19 unclear. The NIH COVID-19 Treatment Guidelines Panel recommends against the use of commercially available IGIV (i.e., non-SARS-CoV-2-specific IGIV) for the treatment of COVID-19 except in the context of a clinical trial and states that current IGIV preparations are not likely to contain SARS-CoV-2 antibodies. This does not preclude the use of IGIV when it is otherwise indicated for the treatment of complications arising during the course of COVID-19 disease. NIH states that there are insufficient data to recommend for or against the use of investigational SARS-CoV-2 immune globulin for the treatment of COVID-19. The Surviving Sepsis Campaign COVID-19 subcommittee suggests that IGIV not be used routinely in critically ill adults with COVID-19 because efficacy data not available, currently available IGIV preparations may not contain antibodies against SARS-CoV-2, and IGIV can be associated with increased risk of severe adverse effects (e.g., anaphylaxis, aseptic meningitis, renal failure, thromboembolism, hemolytic reactions, transfusion-related lung injury).</td>

</table>

**Retrospective observational evaluation of COVID-19 pts treated with ivermectin (not peer reviewed):** Outcome data for 173 pts with confirmed COVID-19 who received at least one dose of oral ivermectin (0.2 mg/kg) at any time during hospitalization, at the discretion of the treating physician, in addition to usual care were compared with outcome data for 107 pts who received usual care. The primary outcome measure was all-cause in-hospital mortality. The investigators reported that overall mortality was lower in the ivermectin group (15%) than in the group not treated with ivermectin (25.2%); there was no difference in duration of hospitalization between the groups (median of 7 days for both groups). **Note:** The effect of ivermectin on viral load was not evaluated and the impact of confounding factors in these patients (e.g., time from diagnosis to initiation of treatment, differences in drugs used for standard care and variances in clinical benefits of such drugs) is not known. **Several clinical trials evaluating ivermectin for the treatment of COVID-19 are registered at clinicaltrials.gov \(^{10}\)**
| Drug(s)             | AHFS Class | Rationale                                                                 | Trials or Clinical Experience                                                                                                                                                                                                 | Dosage<sup>a</sup>                                                                                                                                                                                                 | Comments                                                                                                                                                                                                 |
|---------------------|------------|---------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Nebulized drugs     |            | **Potential harm:** Concern that use of nebulized drugs (e.g., albuterol) for the management of respiratory conditions in patients with COVID-19 infection may distribute the virus into the air and expose close contacts.<sup>1,2,4,5</sup> | Nebulizer treatment used in clinical practice to treat influenza and other respiratory infections is thought to generate droplets or aerosols. In one study, nebulized saline delivered droplets in the small- and medium-size aerosol/droplet range. These results may have infection control implications for airborne infections, including severe acute respiratory syndrome and pandemic influenza infection.<sup>3</sup> |                                                                                                                                                                                                                                                                       | American College of Allergy, Asthma & Immunology (ACAAI) recommends that nebulized albuterol should be administered in a location that minimizes exposure to close contacts who do not have COVID-19 infection. In the home, choose a location where air is not recirculated (e.g., porch, patio, or garage) or areas where surfaces can be cleaned easily or may not need cleaning.<sup>2,4</sup> |
| Niclosamide         | 8:08       | **Broad antiviral activity** In vitro evidence of activity against SARS-CoV and MERS-CoV<sup>1,2</sup> | Currently no known published clinical trial data regarding efficacy or safety in the treatment of COVID-19  
In drug repurposing screens, was found to inhibit replication and antigen synthesis of SARS-CoV, did not interfere with virion’s attachment into cells<sup>2,2</sup>  
Randomized, open-label, controlled trial in France (<sup>NCT04372082</sup>; HYdiLIC) to evaluate niclosamide in adults with SARS-CoV-2 infection (asymptomatic or onset of symptoms less than 8 days previously) and comorbidities<sup>3</sup> | Protocol in one ongoing trial (<sup>NCT04372082</sup>) specifies a niclosamide dosage of 2 g on day 1, then 500 mg twice daily for 10 days for treatment of COVID-19 in adults<sup>3</sup>  
Protocol in one ongoing trial (<sup>NCT04399356</sup>) specifies a niclosamide dosage of 2 g orally once daily for 7 days for treatment of mild to moderate COVID-19 in adults<sup>3</sup>  
Protocols in two ongoing trials (<sup>NCT04436458</sup>, <sup>NCT04542434</sup>) specify a 3-times-daily niclosamide regimen (e.g., 400 mg of niclosamide<sup>4</sup>) | Not commercially available in the US  
No data to date support use in treatment of COVID-19  

Updated 10-1-20. The current version of this document can be found on the [ASHP COVID-19 Resource Center](https://www.ashp.org/covid19). This work is licensed under a [Creative Commons Attribution-NonCommercial 4.0 International License](https://creativecommons.org/licenses/by-nc/4.0/).
### Drug(s)
Nitazoxanide

### AHFS Class
8:30.92 Antiprotozoal

### Rationale
- **In vitro activity against various viruses, including coronaviruses:**
  - Structurally similar to niclosamide
  - In vitro evidence of activity against SARS-CoV-2
  - In vitro activity against MERS-CoV
  - Suppresses production of proinflammatory cytokines in peripheral blood mononuclear cells; suppresses IL-6 in mice
  - Some in vitro evidence of potential synergism between nitazoxanide and remdesivir and between nitazoxanide and umifenovir against SARS-CoV-2; additional data needed.

### Trials or Clinical Experience
- **Randomized, double-blind placebo-controlled trial in Boston (NCT04399356) to evaluate niclosamide in adults with mild to moderate COVID-19**
- **Randomized, double-blind placebo-controlled trials (NCT04436458, NCT04542434) to evaluate niclosamide in adults with moderate COVID-19 with GI signs and symptoms**

### Dosage
- Orally 3 times daily for 14 days for treatment of moderate COVID-19 in adults with GI signs and symptoms

### Comments
- **Dosages investigated for treatment of influenza and influenza-like illness or being investigated for other viral infections:** Adults and adolescents (≥12 years of age): 500 or 600 mg orally twice daily for 5 days (NCT04423861) or four times daily for 5-14 days or 1 g twice daily for 7 or 14 days for treatment of COVID-19 in adults.
- Protocol in two ongoing trials sponsored by the manufacturer (NCT04331208, NCT04359680) evaluating postexposure prophylaxis of COVID-19 and other viral respiratory illnesses specifies a nitazoxanide dosage of 600 mg orally twice daily for 6 weeks in adults; another study (NCT04435314) specifies a dosage of 600 mg 3 times daily for 7 days for postexposure prophylaxis in adults.
- Results of a physiologically based pharmacokinetic model predict that nitazoxanide dosages of 1200 mg 4 times daily, 1600 mg 3 times daily, and 2900 mg twice daily in the faeces state and 700 mg 4 times daily, 900 mg 3 times daily, and 1400 mg twice daily in the fed state are capable of maintaining plasma and lung tizoxanide (major metabolite of nitazoxanide) exposures exceeding the EC<sub>90</sub> for SARS-CoV-2.

| **Nonsteroidal Anti-inflammatory Agents (NSAIAs)** | 28:08.04   | *Ibuprofen*: Speculative link between ibuprofen and increased ACE2 expression, which possibly could lead to worse outcomes in COVID-19 patients 1  
*Indomethacin*: In vitro antiviral activity in SARS-CoV-2 pseudovirus-infected Vero E6 cells; 7 also has in vitro activity against other coronaviruses: SARS-CoV-1 (in Vero E6 and human pulmonary epithelial [A549] cells) and canine coronavirus; also has in vivo activity against canine coronavirus in dogs 6, 7 (interferes with viral RNA synthesis) 6, 8  | Multiple other clinical trials planned or initiated to evaluate nitazoxanide in combination with other drugs (e.g., hydroxychloroquine, ivermectin) or alone for treatment of COVID-19 8  |          |

Concerns that anti-inflammatory drugs such as ibuprofen may worsen COVID-19 circulated widely in the early months of the pandemic. 5, 10, 12, 14 These reports were based largely on a letter published in *The Lancet Respir Med* stating that increased expression of ACE2 could facilitate infection with COVID-19 and that ibuprofen can increase ACE2. 1, 4 In addition, there were unconfirmed reports of younger, healthy patients who had used ibuprofen to treat early symptoms of COVID-19 and later experienced severe outcomes. 10, 12, 14

A statement attributed to the WHO recommending paracetamol and avoiding ibuprofen as a self-medication was widely circulated in the media; however, such a position by the WHO has not been substantiated. WHO subsequently performed a rapid review of the literature and concluded that there was no evidence at that time of severe adverse events or effects on acute health care utilization, long-term survival, or quality of life in patients with COVID-19 as a result of the use of NSAIAs. 9

FDA has stated that it is not aware of scientific evidence connecting the use of NSAIAs, such as ibuprofen, with worsening COVID-19 symptoms and will communicate publicly when more information is available. FDA also noted that all prescription NSAIA labels warn that ibuprofen (200 mg) sold over the counter (OTC) in packages of no more than 20 tablets, and such OTC purchases of ibuprofen constituted 15% of total ibuprofen sales and a smaller proportion of total NSAIA sales. This definition of NSAIA use was a major limitation of the study 14

Ibuprofen: *In a retrospective cohort study* of 403 hospitalized patients with COVID-19 at a single center in Israel, use of ibuprofen (1 week prior to diagnosis or during the course of disease) was not associated with increased mortality or the need for respiratory support compared with acetaminophen or no antipyretic drug. 15

*Indomethacin*: In *vivo studies and animal models only*; 6, 7 currently no published studies evaluating use specifically in COVID-19 patients

Although there currently is no compelling evidence to support an association between ibuprofen and negative outcomes in patients with COVID-19, some

</tbody>
</table>

<sup>a</sup> Experts have recommended preferentially using acetaminophen for treatment of fever<sup>2, 3, 4, 10</sup>  

**NIH COVID-19 Treatment Guidelines Panel** states that patients who are receiving NSAIDs for other conditions should continue receiving the drugs; the panel also states that antipyretic strategy (e.g., use of acetaminophen or NSAIDs) should be no different between patients with or without COVID-19.<sup>5</sup>  

The Surviving Sepsis Campaign COVID-19 guidelines state that until more evidence is available, use of acetaminophen over no treatment for fever control is suggested (weak recommendation)<sup>7</sup>  

IDSA makes no specific recommendation for or against the use of NSAIDs in patients with COVID-19<sup>12</sup>

<tr>
<td></td>
<td></td>
<td>A consistent finding in patients with ARDS (regardless of the cause) is fibrin deposition and microthrombi formation in the alveoli and pulmonary vasculature.</td>
<td>Other case series have described the use of t-PA in COVID-19 patients with severe respiratory failure or ARDS who were rapidly deteriorating and were either already on mechanical ventilation or likely to require intubation. Following IV infusion of t-PA (dosages varied), the majority of patients responded with rapid improvement in oxygenation. However, multiple confounding factors limit interpretation of findings from these case reports.</td>
<td>of administration, and duration of treatment remain to be determined.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Dysregulation of the clotting system in ARDS is a result of both enhanced activation of coagulation and suppression of fibrinolysis.</td>
<td>An open-label, randomized trial (NCT04357730) is being conducted to evaluate systemic fibrinolytic therapy with t-PA versus standard of care in mechanically ventilated COVID-19 patients with severe respiratory failure.</td>
<td><strong>Tenecteplase: A low-dose IV bolus of tenecteplase (0.25 mg/kg or 0.5 mg/kg) is being evaluated in the registered NCT04505592 trial.</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Fibrinolysis shutdown, as evidenced by complete failure of clot lysis on thromboelastography, has been observed in critically ill patients with COVID-19.</td>
<td>An open-label, nonrandomized pilot study (NCT04356833) is being conducted to evaluate an inhaled formulation of t-PA (via nebulization) in patients with ARDS due to COVID-19; the inhaled formulation of t-PA is investigational at this time.</td>
<td><strong>The CHEST guideline for the prevention, diagnosis, and treatment of VTE in patients with COVID-19 states that there is a lack of evidence regarding use of thrombolytic therapies in critically ill patients with COVID-19 without objective evidence of VTE or VTE-associated hypotension; based on indirect evidence from other populations, the expert panel recommends against the use of thrombolytic therapy in COVID-19 patients without objectively confirmed PE and PE-induced hypotension.</strong></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>Thrombolytic therapy may restore microvascular patency and limit progression of ARDS in patients with COVID-19.</td>
<td><strong>A phase 3 randomized, double-blind, placebo-controlled study (NCT04453371; AtTAC) has been initiated to evaluate t-PA (alteplase) IV infusion in patients with ARDS due to COVID-19.</strong></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td><strong>Several randomized, double-blind, placebo-controlled trials have been initiated to evaluate low-dose IV bolus tenecteplase in conjunction with anticoagulation for the treatment of COVID-19-associated respiratory failure, including the following trials:</strong></td>
<td><strong>The Anticoagulation Forum recommends against the use of thrombolytic agents in COVID-19 patients outside the setting of a clinical trial unless there is another clinical indication (e.g., STEMI, acute ischemic stroke, high-risk [massive] PE with hemodynamic compromise); in general, thrombolytic therapy is not recommended in the vast majority of patients with PE given limited efficacy data in patients who are hemodynamically stable.</strong></td>
<td></td>
