Assessment of Evidence for COVID-19-Related Treatments: Updated 9/17/2020

The information contained in this evidence table is emerging and rapidly evolving because of ongoing research and is subject to the professional judgment and interpretation of the practitioner due to the uniqueness of each medical facility’s approach to the care of patients with COVID-19 and the needs of individual patients. ASHP provides this evidence table to help practitioners better understand current approaches related to treatment and care. ASHP has made reasonable efforts to ensure the accuracy and appropriateness of the information presented. However, any reader of this information is advised ASHP is not responsible for the continued currency of the information, for any errors or omissions, and/or for any consequences arising from the use of the information in the evidence table in any and all practice settings. Any reader of this document is cautioned that ASHP makes no representation, guarantee, or warranty, express or implied, as to the accuracy and appropriateness of the information contained in this evidence table and will bear no responsibility or liability for the results or consequences of its use.

ASHP’s patient medication information is available at [http://www.safemedication.com/](http://www.safemedication.com/). Visit our [website](http://www.ashp.org) for the latest information on current drug shortages.

Selected entries were updated 9/17/20; these can be identified by the date that appears in the Drug(s) column. Within updated entries, select revisions that include the most important new information (e.g., new clinical trial data, new or revised guidance) are marked by **.

**TABLE OF CONTENTS**

**ANTIVIRAL AGENTS**
- **BALOXAVIR**
- **CHLOROQUINE PHOSPHATE**
- **FAVIPIRAVIR** (Avigan®, Avifavir®, Favilavir)
- **HIV PROTEASE INHIBITORS** (e.g., LPV/RTV, Kaletra®)
- **HYDROXYCHLOROQUINE** (Plaquenil®)
- **NEURAMINIDASE INHIBITORS** (e.g., oseltamivir)
- **REMDESVIR** (Veklury®)
- **UMIFENOVIR** (Arbidol®)

**SUPPORTING AGENTS**
- **ANAKINRA** (Kineret®)
- **ASCORBIC ACID**
- **AZITHROMYCIN**
- **BARICITINIB** (Olumiant®)
- **COLCHICINE**
- **CORTICOSTEROIDS** (systemic)
- **CORTICOSTEROIDS** (inhaled)
- **INHALED PROSTACYCLINS**
- **INTERFERONS**
- **NITRIC OXIDE** (inhaled)
- **RUXOLITINIB** (Jakafi®)
- **SARILUMAB** (Kevzara®)
- **SILTUXIMAB** (Sylvant®)
- **SIROLIMUS** (Rapamune®)
- **TOCILIZUMAB** (Actemra®)
- **VITAMIN D**
- **ZINC**

**OTHER**
- **ACE INHIBITORS, ANGIOTENSIN II RECEPTOR BLOCKERS (ARBs)**
- **ANTICOAGULANTS**
- **COVID-19 CONVALESCENT PLASMA**
- **FAMOTIDINE**
- **HMG-CoA REDUCTASE INHIBITORS** (statins)
- **IMMUNE GLOBULIN**
- **IVERMECTIN**
- **NEBULIZED DRUGS**
- **NICLOSAMIDE**
- **NITAZOXANIDE**
- **NONSTEROIDAL ANTI-INFLAMMATORY AGENTS (NSAIAs)**
- **TISSUE PLASMINOGEN ACTIVATOR** (t-PA; alteplase)

<td><strong>Baloxavir</strong>&lt;br&gt;Updated 9/10/20</td>
<td>8:18.92 Antiviral</td>
<td>Antiviral active against influenza viruses&lt;br&gt;<strong>In vitro antiviral activity against SARS-CoV-2 demonstrated in one trial</strong>&lt;sup&gt;1&lt;/sup&gt;</td>
<td><strong>Only very limited data available</strong> regarding use of baloxavir for treatment of COVID-19&lt;br&gt;Exploratory, open-label, randomized controlled study at a single center in China (ChiCTR2000029544): 29 adults hospitalized with COVID-19 receiving antiviral treatment with lopinavir/ritonavir, darunavir/cobicistat, or umifenovir (Arbidol®), in combination with inhaled interferon-α, were randomized to treatment with baloxavir marboxil (80 mg orally on day 1 and on day 4, and 80 mg orally on day 7 as needed) (n=10), favipiravir (1600 or 2200 mg orally on day 1, followed by 600 mg three times daily for up to 14 days) (n=9), or control (standard antiviral treatment) (n=10). Percentage of pts with viral conversion (2 consecutive tests with undetectable viral RNA results) after 14 days of treatment was 70, 77, and 100% in the baloxavir, favipiravir, and control groups, respectively, with median time to clinical improvement of 14, 14, and 15 days, respectively.&lt;sup&gt;1&lt;/sup&gt; There are no clinical trials registered at clinicaltrials.gov to evaluate baloxavir for treatment of COVID-19.</td>
<td>A baloxavir marboxil dosage of 80 mg on day 1 and on day 4, and another dose of 80 mg on day 7 (as needed; not to exceed 3 total doses) was used in one open-label COVID-19 study in adults in China.&lt;sup&gt;2&lt;/sup&gt;</td>
<td>No data support use of baloxavir in the treatment of COVID-19</td>
</tr>
<tr>
<td><strong>Chloroquine Phosphate</strong>&lt;br&gt;Updated 9/3/20</td>
<td>8:30.08 Antimalarial (4-aminoquinoline derivative) &lt;br&gt;<strong>Oral chloroquine phosphate dosage</strong>&lt;br&gt;Optimal dosage and duration of treatment not known&lt;sup&gt;25&lt;/sup&gt; &lt;br&gt;Consider: 500 mg of chloroquine phosphate is equivalent to 300 mg of chloroquine base&lt;sup&gt;17&lt;/sup&gt; &lt;br&gt;<strong>Oral chloroquine phosphate dosage suggested in the EUA (now revoked):</strong> For treatment of hospitalized adults and adolescents weighing 50 kg or more, suggested dosage was 1 g on day 1, then 500 mg daily for 4-7 days of total treatment based on clinical evaluation.&lt;sup&gt;25&lt;/sup&gt; FDA now states that this dosage regimen is unlikely to have an antiviral effect in pts with COVID-19 based on a reassessment of in vitro EC&lt;sub&gt;50&lt;/sub&gt;/EC&lt;sub&gt;90&lt;/sub&gt; data and efficacy and safety of chloroquine for treatment or prevention of COVID-19 not established&lt;sup&gt;10, 24, 39&lt;/sup&gt;</td>
<td><strong>Only limited clinical trial data available</strong> to date to evaluate use of chloroquine for treatment or prevention of COVID-19&lt;br&gt;<strong>Clinical experience</strong> in treating pts with COVID-19: Majority of data to date involves use in pts with mild or moderate COVID-19;&lt;sup&gt;35&lt;/sup&gt; only limited clinical data on use in pts with severe and critical disease.&lt;br&gt;<strong>Small, randomized study in hospitalized adults in China compared chloroquine with LPV/RTV (Huang et al):</strong> 10 pts (7 with moderate and 3 with severe COVID-19) received chloroquine (500 mg twice daily for 10 days) and 12 pts (7 with moderate and 5 with severe COVID-19) received LPV/RTV (lopinavir 400 mg/ritonavir 100 mg twice daily for 10 days). All 10 pts treated with clinical efficacy for treatment or prevention of COVID-19 needed to substantiate initial reports of efficacy of 4-aminoquinoline antimalarials for treatment of COVID-19, guide decisions regarding the most appropriate pts for treatment with such drugs, and identify optimal dose and treatment duration</td>
<td>No data to date indicating that in vitro activity against SARS-CoV-2 corresponds with clinical efficacy for treatment or prevention of COVID-19&lt;br&gt;Data from randomized, controlled clinical trials needed to substantiate initial reports of efficacy of 4-aminoquinoline antimalarials for treatment of COVID-19, guide decisions regarding the most appropriate pts for treatment with such drugs, and identify optimal dose and treatment duration</td>

<th>Trials or Clinical Experience</th>
<th>Dosage</th>
<th>Comments</th>
</tr>
</thead>
</table>
| patients with viral infections 13, 15-16 | | | with chloroquine had negative RT-PCR results for SARS-CoV-2 by day 13 and were discharged from the hospital by day 14; 11/12 pts (92%) treated with LPV/RTV were negative for SARS-CoV-2 at day 14 and only 6/12 (50%) were discharged from the hospital by day 14. **Note:** Results suggest that chloroquine was associated with shorter time to RT-PCR conversion and quicker recovery than LPV/RTV; however, this study included a limited number of pts and the median time from onset of symptoms to initiation of treatment was shorter in those treated with chloroquine than in those treated with LPV/RTV (2.5 vs 6.5 days, respectively). 20 | **Double-blind, randomized, phase 2b study in Brazil (Borba et al; NCT04323527): Efficacy and safety of two different chloroquine dosages were evaluated for adjunctive therapy in hospitalized adults with severe COVID-19.** According to the initial study protocol, pts were randomized 1:1 to receive high-dose chloroquine (600 mg twice daily for 10 days) or lower-dose chloroquine (450 mg twice daily on day 1, then 450 mg once daily on days 2-5); all pts also received azithromycin and ceftriaxone and some also received oseltamivir. An unplanned interim analysis was performed and the high-dose arm of the study was halted because of toxicity concerns, particularly QTc prolongation and ventricular tachycardia, and because more deaths were reported in this arm. Analysis of data available for the first 81 enrolled pts indicated that, by day 13, 16/41 pts (39%) treated with the high-dose regimen had died vs 6/40 (15%) treated with the lower-dose regimen. QTc >500 msec occurred more frequently in the high-dose group (18.9%) than in the lower-dose group (11.1%). **Note:** The high-dose arm included more pts prone to cardiac complications than the lower-dose arm. Data at the time of the interim analysis were insufficient to evaluate efficacy. 35 | **Calculated lung concentrations:** it is unclear whether this dosage regimen would provide any beneficial immunomodulatory effects. 57  
**Oral chloroquine phosphate dosage in Chinese guidelines:** 500 mg twice daily for 7 days (adults 18-65 years weighing >50 kg); 500 mg twice daily on days 1 and 2, then 500 mg once daily on days 3-7 (adults weighing <50 kg) 11 | Additional data needed regarding toxicity profile when used in patients with COVID-19  
NIH COVID-19 Treatment Guidelines Panel recommends against use of chloroquine for the treatment of COVID-19 in hospitalized pts and recommends against use of chloroquine for the treatment of COVID-19 in nonhospitalized patients, except in a clinical trial. The panel also recommends against use of high-dose chloroquine (i.e., 600 mg twice daily for 10 days) for the treatment of COVID-19 because such dosage has been associated with more severe toxicities compared with lower-dose chloroquine. 35  
IDSA recommends against use of chloroquine for the treatment of COVID-19 in hospitalized pts and also recommends against use of a combined regimen of chloroquine and azithromycin for the treatment of COVID-19 in hospitalized pts. 38  
NIH COVID-19 Treatment Guidelines Panel recommends against the use of any agents, including chloroquine, for preexposure prophylaxis (PrEP) or post-exposure prophylaxis (PEP) for prevention of SARS-CoV-2 infection, except in a clinical trial. The panel states that, to date, no agent is known to be effective for preventing SARS-CoV-2 infection when given before or after an exposure. 35  
Because 4-aminoquinolines (chloroquine, hydroxychloroquine) are associated with QT prolongation and cardiac arrhythmias; 13, 15, 36, 39 diagnostic testing and monitoring recommended to minimize risk of adverse effects, including drug-induced cardiac effects. 35, 36, 39 (See Hydroxychloroquine in this Evidence Table.) |

Emergency use authorization (EUA) for chloroquine (now revoked): Effective June 15, 2020, FDA has revoked the EUA for chloroquine and hydroxychloroquine previously issued on March 28, 2020 that permitted distribution of the drugs from the strategic national stockpile (SNS) for use in adults and adolescents weighing 50 kg or more hospitalized with COVID-19 for whom a clinical trial was not available or participation not feasible. 24, 57 Based on a review of new information and reevaluation of information available at the time the EUA was issued, FDA concluded that the original criteria for issuance of the EUA for these drugs are no longer met. 57 Based on the totality of scientific evidence available, FDA concluded that it is unlikely that chloroquine and...

<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td><strong>In a small, open-label, nonrandomized study</strong> in patients with non-severe COVID-19 in China (ChiCTR2000029600), favipiravir (1600 mg orally twice daily on day 1, then 600 mg orally twice daily on days 2–14) (n=35) was associated with decreased median time to viral clearance (4 vs 11 days) and higher improvement rate on chest CT imaging on day 14 (91 vs 62%) compared with the control group receiving lopinavir/ritonavir (n=45); both groups also received aerosolized interferon α-1b.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td><strong>In a retrospective, observational, multicenter study</strong> in 63 adults with COVID-19 in Thailand who received favipiravir (median loading dose of 47.4 mg/kg on day 1 and median maintenance doses of 17.9 mg/kg per day for a median total duration of 12 days), clinical improvement at day 7 was reported in 66.7% of patients (92.5% in patients not requiring oxygen supplementation, 47.2% in patients requiring oxygen supplementation) and clinical improvement at day 14 was reported in 85.7% of patients (100% in patients not requiring oxygen supplementation, 75% in patients requiring oxygen supplementation). Overall mortality at day 28 was 4.8%. Nearly all patients also received a chloroquine-based therapy and an HIV protease inhibitor. Multivariate analysis revealed that older age, higher baseline disease severity, and loading doses &lt;45 mg/kg per day were negative predictors of early clinical improvement.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td><strong>In a case series</strong> of 11 adults admitted to the ICU with COVID-19 at a single center in Japan from 4/6/20 to 4/21/20 who received favipiravir (3600 mg on day 1, then 1600 mg daily thereafter for a median of 14 days) in combination with nafamostat mesylate (not commercially available in the US), 8 pts required mechanical ventilation at baseline and 7 of these were weaned from mechanical ventilation and 1 died.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td><strong>COVID-19</strong>. One such favipiravir regimen used in the treatment of Ebola virus disease includes a loading dosage of 6000 mg (doses of 2400 mg, 2400 mg, and 1200 mg given 8 hours apart on day 1), then a maintenance dosage of 1200 mg every 12 hours on days 2–10.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>For the treatment of COVID-19, one pharmacokinetic simulation model suggested that a dosage of 2400 mg twice daily on day 1, followed by 1600 mg twice daily on days 2–10 should achieve adequate favipiravir trough plasma concentrations and may be more pharmacologically relevant than lower dosages.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Pharmacokinetic data are available from a study in critically ill pts with COVID-19 requiring mechanical ventilation who received a favipiravir dosage of 1600 mg twice daily on day 1, then 600 mg twice daily on days 2–5 (or longer if needed) via NG tube. Trough serum concentrations of the drug in most samples were lower than the lower limit of quantification and lower than the in vitro EC₅₀ of the drug reported for SARS-CoV-2; trough concentrations in these critically ill pts also were much lower than those previously reported in healthy individuals who received the same dosage.</td>

<tr>
<td>HIV Protease Inhibitors</td>
<td>8:18.08.08</td>
<td>HIV Protease Inhibitors</td>
<td>In other small case series and case reports of adults with critical or severe COVID-19 pneumonia in Japan (total of 15 pts) who received favipiravir (e.g., 1800 mg twice daily on day 1, then 800 mg twice daily for 9 or 13 days) in combination with other treatments (e.g., systemic corticosteroids), improvements in respiratory status and chest imaging studies were reported. US: Randomized, controlled open-label proof-of-concept trial (NCT04358549) of favipiravir for the treatment of COVID-19. US: Randomized, double-blind, placebo-controlled trial (NCT04346628) to evaluate efficacy of favipiravir in pts with mild or asymptomatic COVID-19. Multiple clinical trials initiated in pts with COVID-19 in China, Japan, and other countries to evaluate favipiravir alone or in conjunction with other antivirals or other agents.</td>
<td>LPV/RTV (COVID-19): LPV 400 mg/RTV 100 mg orally twice daily for 10-14 days 9, 10, 14</td>
<td>LPV/RTV: Efficacy for the treatment of COVID-19, with or without other antivirals, not established. Darunavir: Manufacturer states they have no clinical or pharmacologic evidence to support use of DRV/c for treatment of COVID-19. Results of an open-label, controlled study in China indicated that a 5-day regimen of DRV/c was not effective for treatment of COVID-19. There are no published clinical studies that have evaluated efficacy and safety of DRV/RTV or the fixed combination of DRV, cobicistat, emtricitabine, and tenofovir alafenamide for treatment of COVID-19. Atazanavir, Nelfinavir, Saquinavir, Tipranavir: No data to date to support use in the treatment of COVID-19. NIH COVID-19 Treatment Guidelines Panel recommends against the use of LPV/RTV or other HIV protease inhibitors for the treatment of COVID-19, except in the context of a clinical trial.</td>
</tr>
<tr>
<td>Updated 9/3/20</td>
<td></td>
<td>Lopinavir (LPV): Some evidence of in vitro activity against SARS-CoV-2 in Vero E6 cells; evidence of in vitro activity against SARS-CoV-1 and MERS-CoV; some evidence of benefit in animal studies for treatment of MERS-CoV. Atazanavir (ATV): Some evidence that ATV alone or with ritonavir (ATV/RTV) has in vitro activity against SARS-CoV-2 in Vero E6 cells, human epithelial pulmonary cells (A549), and human monocytes. Darunavir (DRV): In one study, DRV with cobicistat had no in vitro activity against SARS-CoV-2 at clinically relevant concentrations in Caco-2 cells; in another study, high DRV concentrations were</td>
<td>Lopinavir and Ritonavir (LPV/RTV; Kaletra®) randomized, open-label trial in China (Cao et al) in hospitalized adults with severe COVID-19 compared LPV/RTV in conjunction with standard care (99 pts) vs standard care alone (100 pts). Primary end point was time to clinical improvement (time from randomization to improvement of two points on a seven-category ordinal scale or hospital discharge, whichever came first). In ITT population, time to clinical improvement was not shorter with LPV/RTV compared with standard care (median time to clinical improvement 16 days in both groups); in modified ITT population, median time to clinical improvement 15 days in LPV/RTV group and 16 days in standard care only group. The 28-day mortality rate was numerically lower in LPV/RTV group (19.2% vs 25% in ITT population; 16.7% vs 25% in modified ITT population). Some evidence that LPV/RTV initiation within 12 days after symptom onset is associated with shorter time to clinical improvement. No significant differences in reduction of viral RNA load, duration of viral RNA detectability, duration of oxygen</td>
<td>LPV/RTV (COVID-19): LPV 400 mg/RTV 100 mg orally twice daily for 10-14 days 3, 12, 14</td>
<td></td>

<td>LPV/RTV with ribavirin and interferon β-1b vs LPV/RTV alone in open-label, randomized trial in adults with mild to moderate COVID-19 in Hong Kong (Hung et al; NCT04276688): 127 pts were randomized 2:1 to receive LPV/RTV (LPV 400 mg/RTV 100 mg) twice daily for 14 days) with ribavirin (400 mg twice daily) and interferon β-1b (8 million IU sub-Q on alternate days for up to 3 doses depending on how soon treatment initiated after symptom onset) or a 14-day regimen of LPV/RTV alone. Median time to negative RT-PCR results for SARS-CoV-2 in nasopharyngeal samples was 7 days in pts treated with the 3-drug regimen vs 12 days in those treated with LPV/RTV alone; median duration of hospitalization was 9 or 14.5 days, respectively. Adverse effects reported in 48% of those treated with the 3-drug regimen and in 49% of those treated with LPV/RTV alone. 24</td>

Known pharmacokinetics and toxicity profile based on use for other indications.\textsuperscript{13} Hydroxyl analog of chloroquine with similar mechanisms of action and adverse effects;\textsuperscript{13, 14} may have more favorable dose-related toxicity profile than chloroquine,\textsuperscript{13,16} but cardiotoxicity (e.g., prolonged QT interval) is a concern with both drugs.\textsuperscript{13, 15}

Drug(s) | AHFS Class | Rationale | Trials or Clinical Experience | Dosage\textsuperscript{a} | Comments
--- | --- | --- | --- | --- | ---
hydroxychloroquine |  | drug (data unclear for 3 pts); median duration from hospitalization to negative conversion and to temperature normalization were similar in both groups; evidence of radiologic progression on CT in 5 pts treated with the drug and 7 pts not treated with the drug (all pts showed improvement at follow-up).\textsuperscript{16} Hydroxychloroquine randomized, parallel-group study in adults in China (ChiCTR2000029559): 31 pts with COVID-19 and pneumonia received hydroxychloroquine sulfate (200 mg twice daily for 5 days) and standard treatment (O\textsubscript{2}, antiviral agents, antibacterial agents, immunoglobulin, with or without corticosteroids) and 31 other pts received standard treatment alone (control group). Exclusion criteria included severe and critical illness. Pts assessed at baseline and 5 days after treatment initiation for time to clinical recovery (TTCR; defined as normalization of fever and cough relief maintained for >72 hours), clinical characteristics, and changes on chest CT. It was concluded that hydroxychloroquine was associated with symptom relief since time to fever normalization was shorter in hydroxychloroquine group (2.2 days) vs control group (3.2 days), time to cough remission was shorter in hydroxychloroquine group, and pneumonia improved in 25/31 pts (80.6%) in hydroxychloroquine group vs 17/31 pts (54.8%) in control group. Total of 4 pts progressed to severe illness (all in the control group).\textsuperscript{31} Note: This study did not include pts with severe disease and pts received other anti-infectives in addition to hydroxychloroquine. At study entry, 9 pts without fever and 9 pts without cough were included in hydroxychloroquine group and 14 pts without fever and 16 pts without cough were included in control group; unclear how these pts were addressed in TTCR calculations. Although initial registered study protocol specified 2 different hydroxychloroquine treatment groups and a placebo group (each with 100 pts) and primary end points of time to negative nucleic acid and T-cell recovery,\textsuperscript{32} data provided only for certain clinical symptoms
hydroxychloroquine sulfate |  | Oral hydroxychloroquine sulfate dosage used or being investigated in clinical trials: 400 mg once or twice daily for 5-10 days.\textsuperscript{10, 18} Oral hydroxychloroquine sulfate with azithromycin (France): 200 mg 3 times daily for 10 days with or without azithromycin ([500 mg on day 1, then 250 mg once daily on days 2-5])\textsuperscript{7, 34, 40}
Data from randomized, controlled clinical trials are insufficient to date to draw any conclusions regarding possible benefits and safety of using hydroxychloroquine with azithromycin. (See Azithromycin in this Evidence Table.) Additional data needed regarding toxicity profile when used in patients with COVID-19
NIH COVID-19 Treatment Guidelines Panel recommends against use of hydroxychloroquine for the treatment of COVID-19 in hospitalized pts and recommends against use of hydroxychloroquine for the treatment of COVID-19 in nonhospitalized pts, except in a clinical trial. The panel also recommends against use of hydroxychloroquine with azithromycin for the treatment of COVID-19, except in a clinical trial.\textsuperscript{35}
NIH COVID-19 Treatment Guidelines Panel recommends against use of any agents, including hydroxychloroquine, for preexposure prophylaxis (PrEP) or postexposure prophylaxis (PEP) for prevention of SARS-CoV-2 infection, except in a clinical trial.\textsuperscript{35} The panel states that, to date, no agent is known to be effective for preventing SARS-CoV-2 infection when given before or after an exposure.\textsuperscript{35} Because 4-aminquinolines (hydroxychloroquine, chloroquine) and azithromycin are independently associated with QT prolongation and because concomitant use of the drugs may further increase the risk of QT prolongation, caution is advised if considering use of hydroxychloroquine (with or without azithromycin) in pts with COVID-19 infection.\textsuperscript{35}
NIH COVID-19 Treatment Guidelines Panel recommends against use of hydroxychloroquine for the treatment of COVID-19 in hospitalized pts and also recommends against use of a combined regimen of hydroxychloroquine and azithromycin for the treatment of COVID-19 in hospitalized pts.\textsuperscript{38}

<td><strong>Hydroxychloroquine randomized, parallel-group, open-label study in hospitalized adults with mild to moderate COVID-19 in China (ChiCTR2000029868):</strong> 150 pts (148 with mild to moderate disease and 2 with severe disease) were randomized 1:1 to receive hydroxychloroquine (1200 mg daily for 3 days, then 800 mg daily for total treatment duration of 2-3 weeks) with standard of care or standard of care alone. Mean time from onset of symptoms to randomization was 16.6 days (range: 3-41 days). Standard of care included IV fluids, O2, various antivirals (e.g., umifenovir, LPV/RTV), antibiotics, and/or glucocorticoid therapy. By day 28, 73% of pts (53 treated with hydroxychloroquine with standard of care and 56 treated with standard of care alone) had converted to negative for SARS-CoV-2. The probability of negative conversion by day 28 in those treated with hydroxychloroquine was similar to that in those treated with standard of care alone; the median time to negative seroconversion (6 and 7 days) also was similar in both groups. Adverse effects reported in 30% of those treated with hydroxychloroquine and 9% of those treated with standard of care alone. <strong>Note:</strong> Results indicate that use of hydroxychloroquine in pts with mild to moderate COVID-19 did not provide additional benefits compared with use of standard of care alone.</td>

**NIH panel states that 4-aminoquinolines (hydroxychloroquine, chloroquine) should be used concomitantly with drugs that pose a moderate to high risk for QT prolongation (e.g., antiarrhythmics, antipsychotics, antifungals, fluoroquinolones, macrolides [including azithromycin]) only if necessary. In addition, because of the long half-lives of both hydroxychloroquine (up to 40 days) and azithromycin (up to 72 hours), caution is warranted even when these drugs are used sequentially. The panel states that use of doxycycline (instead of azithromycin) should be considered for empiric therapy of atypical pneumonia in COVID-19 pts receiving hydroxychloroquine (or chloroquine).**

The benefits and risks of hydroxychloroquine (with or without azithromycin) should be carefully assessed; diagnostic testing and monitoring are recommended to minimize risk of adverse effects, including drug-induced cardiac effects.

**FDA issued a safety alert regarding adverse cardiac effects (e.g., prolonged QT interval, ventricular tachycardia, ventricular fibrillation) reported with use of chloroquine or hydroxychloroquine (either alone or in conjunction with azithromycin or other drugs known to prolong QT interval) in hospital and outpatient settings; FDA cautions against use of chloroquine or hydroxychloroquine outside of a clinical trial or hospital setting and urges healthcare professionals and pts to report adverse effects involving these drugs to FDA MedWatch.**

**Emergency use authorization (EUA) for hydroxychloroquine (now revoked): Effective June 15, 2020, FDA has**
in the control group were analyzed. At day 6, 8/14 (57%) in the hydroxychloroquine group, 6/6 (100%) in the hydroxychloroquine and azithromycin group, and 2/16 (12.5%) in the control group had negative PCR results. At day 8, a positive PCR was reported in a pt treated with both drugs who had tested negative at day 6. Note: This was a small nonrandomized study that didn’t appear to be designed to compare hydroxychloroquine vs hydroxychloroquine and azithromycin (pts received antibiotics to prevent bacterial superinfection based on clinical judgment). Data on disease severity were unclear (some asymptomatic pts were included when study initiated) and information on disease progression and clinical outcomes was not presented.

**Hydroxychloroquine with azithromycin open-label, uncontrolled study in France (Molina et al):** 11 adults hospitalized with COVID-19 received hydroxychloroquine (600 mg daily for 10 days) and azithromycin (500 mg on day 1, then 250 mg daily on days 2-5). At time of treatment initiation, 8/11 pts had significant comorbidities associated with poor outcomes and 10/11 had fever and received O₂. Within 5 days, 1 pt died and 2 transferred to ICU; the regimen was discontinued in 1 pt after 4 days because of prolonged QT interval. Nasopharyngeal samples were still PCR positive at days 5 and 6 in 8/10 pts tested. Note: In this small uncontrolled study, hydroxychloroquine and azithromycin regimen did not result in rapid viral clearance or provide clinical benefit.

**Hydroxychloroquine with azithromycin uncontrolled, retrospective, observational study in France (Gautret et al):** The adults with confirmed COVID-19 (including 6 pts included in a previous study by the same group) were treated with hydroxychloroquine sulfate (200 mg 3 times daily for 10 days) and azithromycin (500 mg on day 1, then 250 mg daily on days 2-5). Majority (92%) were considered low risk for clinical deterioration (low national early warning score for COVID-19 based on age, respiratory rate, O₂ saturation, temperature, BP, revoked the EUA for hydroxychloroquine and chloroquine previously issued on March 28, 2020 that permitted distribution of the drugs from the strategic national stockpile (SNS) for use in adults and adolescents weighing 50 kg or more hospitalized with COVID-19 for whom a clinical trial was not available or participation not feasible. Based on a review of new information and reevaluation of information available at the time the EUA was issued, FDA concluded that the original criteria for issuance of the EUA for these drugs are no longer met. Based on the totality of scientific evidence available, FDA concluded that it is unlikely that hydroxychloroquine and chloroquine may be effective in treating COVID-19 and, in light of ongoing reports of serious cardiac adverse events and several newly reported cases of methemoglobinemia in COVID-19 patients, the known and potential benefits of hydroxychloroquine and chloroquine do not outweigh the known and potential risks associated with the use authorized by the EUA. The basis for the FDA decision to revoke the EUA for hydroxychloroquine and chloroquine is summarized below:

1) Suggested hydroxychloroquine and chloroquine dosage regimens as detailed in the EUA fact sheets for healthcare providers are unlikely to produce an antiviral effect.

2) Earlier observations of decreased viral shedding with hydroxychloroquine or chloroquine treatment have not been consistently replicated and recent data from a randomized controlled trial assessing probability of negative conversion showed no difference between hydroxychloroquine and standard of care alone.

3) Current US treatment guidelines do not recommend the use of chloroquine or hydroxychloroquine in hospitalized patients.

<td>pulse, level of consciousness): only 15% had fever; 4 pts were asymptomatic carriers; mean time from onset of symptoms to treatment initiation was 4.9 days. Clinical outcome, contagiousness as assessed by nasopharyngeal PCR assay and culture, and length of stay in infectious disease (ID) unit were evaluated in pts who were treated for at least 3 days and followed for at least 6 days. Favorable outcome was reported for 81.3%; 15% required O₂; 3 pts transferred to ICU; 1 pt died; mean time to discharge from ID unit was 4.1 days. At day 8, PCR results were negative in 93% of those tested; at day 5, viral cultures were negative in 97.5% of those tested. <strong>Note:</strong> Almost all pts were considered low risk for clinical deterioration (including 4 pts described as asymptomatic carriers) and it is unclear how many would have had spontaneous conversion to negative nasopharyngeal samples during same time frame. Although 80 pts were enrolled, PCR results available for fewer pts beginning on day 3 and only 60 pts represented in day 6 data. This was an uncontrolled study and data presented cannot be used to determine whether a regimen of hydroxychloroquine with azithromycin provides benefits in terms of disease progression or decreased infectiousness, especially for pts with more severe disease. Hydroxychloroquine with azithromycin uncontrolled, observational, retrospective analysis in France (Million et al): Data for 1061 pts with PCR-documented SARS-CoV-2 RNA who were treated with a regimen of hydroxychloroquine sulfate (200 mg 3 times daily for 10 days) and azithromycin (500 mg on day 1, then 250 mg daily on days 2-5) were analyzed for clinical outcomes and persistence of viral shedding. Pts were included in the analysis if they received the combined regimen for at least 3 days and were clinically assessable at day 9. There were 56 asymptomatic and 1005 symptomatic pts; the majority (95%) had relatively mild disease and were considered low risk for clinical deterioration; median age was 43.6 years (range: 14-95 years) and mean time between onset of symptoms patients with COVID-19 outside of a clinical trial and the NIH guidelines now recommend against such use outside of a clinical trial. 57 4) Recent data from a large, randomized, controlled trial showed no evidence of benefit in mortality or other outcomes such as hospital length of stay or need for mechanical ventilation for hydroxychloroquine treatment in hospitalized patients with COVID-19. 57  Consult the FDA letter regarding the revocation of the EUA for hydroxychloroquine and chloroquine and the FDA memorandum explaining the basis for the revocation for additional information. 57</td>

</table>
and initiation of treatment was 6.4 days. Within 10 days of treatment, good clinical outcome reported in 973 pts (91.7%) and poor clinical outcome reported in 46 pts (4.3%). Persistent nasal carriage of SARS-CoV-2 reported at completion of treatment in 47 pts (4.4%); 8 pts died.\(^4\)

**Hydroxychloroquine (with or without azithromycin) in a retrospective analysis of patients hospitalized with COVID-19 in US Veterans Health Administration medical centers (Magagnoli et al):** Data for 368 males (median age >65 years) treated with hydroxychloroquine in addition to standard supportive management were analyzed for death rate and need for mechanical ventilation. Death rate was 27.8% (27/97) in those treated with hydroxychloroquine, 22.1% (25/113) in those treated with hydroxychloroquine and azithromycin, and 11.4% (18/158) in those not treated with hydroxychloroquine; rate of ventilation was 13.3, 6.9, and 14.1%, respectively. Use of hydroxychloroquine alone (but not use of hydroxychloroquine and azithromycin) was associated with increased overall mortality compared with no hydroxychloroquine; use of hydroxychloroquine with or without azithromycin did not reduce the risk of mechanical ventilation.\(^4\) **Note:** The pt population included only elderly males 59-75 years of age, many with significant comorbidities. This analysis did not look at efficacy measures.

**Two different retrospective studies analyzed outcome data for hospitalized pts with confirmed COVID-19 in New York to assess the effects of treatment with hydroxychloroquine with or without azithromycin (Rosenberg et al, Geleris et al):** Results of these studies suggest that use of hydroxychloroquine with or without azithromycin is not associated with decreased in-hospital mortality.\(^4\)\(^5\)\(^6\)

**Rosenberg et al** analyzed data for 1438 hospitalized pts (735 received hydroxychloroquine with azithromycin, 271 received hydroxychloroquine alone, 211 received azithromycin alone, 221 received...

Geleris et al analyzed data for 1376 hospitalized pts (811 received hydroxychloroquine [486 of these also received azithromycin] and 565 did not receive hydroxychloroquine [127 of these received azithromycin]) and assessed the primary end point of time from study baseline to intubation or death. Overall, 346 pts (25.1%) progressed to a primary end point of intubation and/or death and the composite end point of intubation or death was not affected by hydroxychloroquine treatment (intubation or death reported in 32.3% of pts treated with hydroxychloroquine and 14.9% of pts not treated with the drug). |  
46  
Large, randomized, controlled, adaptive trial evaluating efficacy of 6 different treatments for prevention of death in hospitalized pts with COVID-19 compared with usual care alone (NCT04381936; RECOVERY): Study protocol included a treatment arm to evaluate efficacy of hydroxychloroquine sulfate (two 800-mg doses given 6 hours apart followed by two 400-mg doses given 12 and 24 hours after the initial dose on day 1, then 400 mg every 12 hours thereafter for 9 days). The investigators announced preliminary results for the hydroxychloroquine treatment arm. A total of 1542 pts were randomized to receive hydroxychloroquine with usual care and 3132 pts were randomized to usual care alone. Data for these pts indicate that hydroxychloroquine did not provide a significant difference in the primary end point of 28-day mortality (25.7% in those treated with hydroxychloroquine with usual care compared with 23.5% in those treated with usual care alone). In addition, there was no evidence of beneficial effects on duration of hospitalization or |

**Trials or Clinical Experience**

**Note:** Data regarding pt demographics and clinical characteristics (e.g., age, disease severity, comorbidities) and time from diagnosis to study enrollment have not been provided to date.

**Retrospective, comparative cohort study evaluating clinical outcomes in hospitalized COVID-19 pts treated with hydroxychloroquine vs hydroxychloroquine with azithromycin vs azithromycin alone (Arshad et al):** Data for 2541 consecutive pts with laboratory-confirmed COVID-19 who were admitted to hospitals within the Henry Ford Health System in Michigan and received hydroxychloroquine and/or azithromycin or did not receive these drugs were analyzed. Median age of patients was 64 years; the majority had BMI of 30 or greater and many had various other comorbidities; 68% received corticosteroid treatment and 4.5% received tocilizumab; mSOFA scores were not available for 25% of pts and data were not available regarding duration of symptoms prior to hospitalization; and the median length of hospitalization was 6 days. The primary end point was inpatient mortality; median follow-up was 28.5 days. Results indicated that crude mortality rates were 18.1% in the entire group, 13.5% in the hydroxychloroquine group, 20.1% in the hydroxychloroquine with azithromycin group, 22.4% in the azithromycin group, and 26.4% in those not treated with hydroxychloroquine and/or azithromycin. The primary causes of mortality were respiratory failure (88%), cardiac arrest (4%), and cardiopulmonary arrest and multi-organ failure (8%). **Note:** Only selected pts with minimal cardiac risk factors received hydroxychloroquine with azithromycin and all pts treated with hydroxychloroquine were monitored closely with telemetry and serial QTc evaluations.

**Open-label, randomized study in hospitalized pts with mild to moderate COVID-19 (Cavalcanti et al; Brazil; NCT04322123):** Adults hospitalized with COVID-19 were randomized 1:1:1 to receive standard care (control group), hydroxychloroquine (400 mg twice daily for 7 days) with standard

<td>COVID-19.</td>
<td></td>
<td></td>
<td>There was no significant reduction in viral load at day 3 or 7 in those treated with hydroxychloroquine vs those treated with usual care only and there was no decrease in median time to resolution of COVID-19 symptoms (10 and 12 days, respectively) and no decrease in risk of hospitalization (7 and 6%, respectively).</td>

**Double-blind, randomized, placebo-controlled study in outpatients with confirmed or probable early COVID-19 (Skipper et al; US and Canada; NCT04308668):** A total of 423 symptomatic adults with laboratory-confirmed COVID-19 or with symptoms compatible with COVID-19 and a high-risk exposure to a contact with laboratory-confirmed COVID-19 were randomized 1:1 to receive hydroxychloroquine (initial dose of 800 mg, 600 mg given 6-8 hours later, then 600 mg once daily for the next 4 days) or placebo. Enrolled pts had been symptomatic for no more than 4 days and did not require hospitalization at the time of enrollment. The primary efficacy end point specified in the initial study protocol was subsequently changed to overall symptom severity over 14 days; symptoms and severity were self-reported by the pts at days 3, 5, 10, and 14 using a survey with a 10-point visual analog scale. Median age of pts was 40 years, 68% reported no chronic medical conditions, 57% were healthcare workers, 25% had been exposed to COVID-19 through household contacts, and 56% of pts had enrolled within 1 day of symptom onset. **Results indicated that a 5-day hydroxychloroquine regimen did not provide any substantial improvement in symptom severity in these outpatients with confirmed or probable COVID-19.** At day 5, 54% of pts in the hydroxychloroquine group and 56% in the placebo group reported symptoms. At day 14, 24% of those treated with hydroxychloroquine had ongoing symptoms compared with 30% of those treated with placebo. Overall, the decrease in prevalence of symptoms and the reduction in symptom severity score over 14 days were not significantly different between the two groups (symptom severity in the 10-point scale...

Large, multinational, retrospective study analyzed outcome data for hospitalized pts with confirmed COVID-19 to assess the effects of hydroxychloroquine or chloroquine used with or without a macrolide (Mehra et al; now retracted): Original publication included data obtained worldwide for 96,032 pts hospitalized with COVID-19 between Dec 20, 2019 and Apr 14, 2020, including 14,888 pts who received chloroquine or hydroxychloroquine with or without a macrolide (azithromycin or clarithromycin) initiated within 48 hours of diagnosis (treatment group) and 81,144 pts who did not receive these drugs (control group). Based on those data, in-hospital mortality rate in the control group was 9.3% compared with 18% in those treated with hydroxychloroquine alone (n=3016), 23.8% in those treated with hydroxychloroquine and a macrolide (n=6221), 16.4% in those treated with chloroquine alone (n=1868), and 22.2% in those treated with chloroquine and a macrolide (n=3783). Note: This published study has now been retracted by the publisher at the request of 3 of the original authors. Concerns were raised with respect to the veracity of the data and analyses conducted by a global healthcare data collaborative.

Hydroxychloroquine for postexposure prophylaxis of COVID-19 randomized, placebo-controlled trial in the US and Canada (NCT04308668): Asymptomatic adults with occupational or household exposure to an individual with COVID-19 were randomly assigned 1:1 to receive postexposure prophylaxis with a 5-day regimen of hydroxychloroquine sulfate (initial 800-mg dose followed by a 600-mg dose given 6-8 hours after first dose on day 1, then 600 mg once daily for 4 additional days) or placebo (folate tablets). A total of 821 asymptomatic adults were enrolled within 4 days.

| after COVID-19 exposure (414 randomized to hydroxychloroquine and 407 randomized to placebo); 66% were healthcare workers. Overall, 88% of participants reported high-risk exposures (occurred at a distance of <6 feet for >10 minutes while not wearing a face mask or eye shield) and the others reported moderate-risk exposures (occurred at a distance of <6 feet for >10 minutes while wearing a face mask but no eye shield). **Note:** Participants were recruited primarily through social media outreach and traditional media platforms and were enrolled using an internet-based survey. The exposure event and subsequent onset of new symptoms and illness compatible with COVID-19 after enrollment were self-reported using email surveys on days 1, 5, 10, and 14 and at 4-6 weeks. Results of these surveys and information obtained using additional forms of follow-up indicated that confirmed or probable COVID-19 (based on self-reported symptoms or PCR testing) developed in 13% of participants overall (107/821) and did not differ significantly between those who received hydroxychloroquine prophylaxis (11.8%) and those who received placebo (14.3%). **Note:** The various limitations of the trial design should be considered when interpreting the results. Exposure to someone with confirmed COVID-19, time from the exposure event to initiation of prophylaxis, and all outcome data (including possible COVID-19 symptoms and PCR test results) were self-reported by study participants. COVID-19 was confirmed with PCR testing in only a small percentage (<3%) of participants who self-reported COVID-19 symptoms. Survey results indicated that full adherence to the 5-day prophylaxis regimen was reported by only 75% of patients randomized to hydroxychloroquine and 83% of those randomized to placebo. In addition, a total of 52 participants did not complete any surveys after study enrollment. 55,56 Multiple clinical trials to evaluate hydroxychloroquine for treatment of COVID-19 are registered at clinicaltrials.gov (some...

- NCT04335552
- NCT04345692
- NCT04351620
- NCT04353037

Multiple clinical trials to evaluate oseltamivir for prevention of COVID-19 in the healthcare setting or in household contacts of patients with the disease are registered at clinicaltrials.gov (some listed below): 10

- NCT04318015
- NCT04318444
- NCT04328961
- NCT04329923
- NCT04334148
- NCT04341441
- NCT04363450
- NCT04353037

In a retrospective case series of 99 adults with COVID-19 at a single center in Wuhan from 1/1/20 to 1/20/20, 76% of patients received antiviral treatment, including oseltamivir (75 mg orally every 12 hours). At the time of evaluation, 58% of patients remained hospitalized, 31% had been discharged, and 11% had died. 1

In a retrospective case series of 79 adults with COVID-19 who were negative for influenza A and B, early use of oseltamivir had no effect on COVID-19 and did not effectively slow the progression of the disease. 6

In a retrospective cohort study of 1190 adults with COVID-19 at a single center in Wuhan from 12/29/19 to 2/28/20, 61.6% of patients received antiviral therapy (e.g., oseltamivir, ganciclovir, lopinavir/ritonavir, interferon, umifenovir). A survival analysis indicated that administration of oseltamivir appeared to have reduced the risk of death in patients with severe disease and seemed to have been associated with less deterioration (i.e., progression from nonsevere to severe disease or severe disease to death). 7

<td>Remdesivir</td>
<td>8:18.32</td>
<td>Antiviral</td>
<td>While oseltamivir is noted to have been widely used for confirmed or suspected COVID-19 cases in hospitals in China, there has been no exact evidence to date that oseltamivir is effective in the treatment of COVID-19. Some clinical trials for COVID-19 that include oseltamivir are listed below: NCT04303299, NCT04261270, NCT04255017, NCT04338698, NCT04516915.</td>
<td>Optimal dosage and duration of remdesivir treatment not known Emergency use authorization (EUA) remdesivir dosage and duration of treatment recommended for hospitalized adults and children weighing 40 kg or more: Loading dose of 200 mg by IV infusion on day 1, followed by maintenance doses of 100 mg by IV infusion once daily from day 2. For pts not requiring invasive mechanical ventilation and/or ECMO, recommended total treatment duration is 5 days; if pt does not demonstrate clinical improvement, treatment may be extended for up to 5 additional days (i.e., up to a total treatment duration of 10 days). For those requiring invasive mechanical ventilation and/or ECMO, recommended total treatment duration is 10 days. Emergency use authorization (EUA) remdesivir dosage and duration of treatment recommended for hospitalized children weighing 3.5 to less than 40 kg (using the lyophilized powder formulation only): Loading dose of 5 mg/kg by IV infusion on day 1, followed by maintenance doses of 2.5 mg/kg by IV infusion once daily from day 2. For pts not requiring invasive mechanical ventilation and/or ECMO, recommended total treatment duration is 5 days, if pt does not demonstrate clinical improvement.</td>

<td>(Veklury®)</td>
<td>Updated</td>
<td>9/3/20</td>
<td>In vitro evidence of activity against SARS-CoV-2 in Vero E6 cells. In Rhesus macaques infected with SARS-CoV-2, treatment with a 6-day regimen of IV remdesivir initiated 12 hours after virus inoculation was associated with some benefits (lower disease severity scores, fewer pulmonary infiltrates, lower virus titers in bronchoalveolar lavage samples) compared with vehicle control; remdesivir treatment did not reduce viral loads or infectious virus titers in nose, throat, or rectal swabs compared with vehicle control. In vitro activity against SARS-CoV and MERS-CoV; active in animal models of SARS and MERS; prevented MERS in Rhesus macaques when given before infection and provided benefits when given after animal already infected.</td>
<td>Randomized, double-blind, placebo-controlled trial in hospitalized adults with severe COVID-19 in China (NCT04257656; Wang et al): Pts were randomized 2:1 to receive remdesivir (200 mg IV on day 1, then 100 mg IV once daily on days 2-10) or placebo initiated within 12 days of symptom onset. Primary outcome was time to clinical improvement within 28 days after randomization or hospital discharge, whichever came first. IIT population included 158 pts treated with remdesivir and 78 pts treated with placebo; 32% of pts also received interferon α-2b, 28% also received LPV/RTV, and 66% also received corticosteroids during hospitalization. Median time to clinical improvement was not significantly different in remdesivir group (21 days) vs placebo group (23 days); 28-day mortality rate was similar in both groups (14 vs 13%). When remdesivir was initiated within 10 days of symptom onset, median time to clinical improvement was numerically shorter (but not statistically significant) compared with placebo group (18 vs 23 days). Duration of invasive mechanical ventilation was numerically shorter (but not statistically significant) in remdesivir group; only a small percentage of pts (0.4%) were on invasive mechanical ventilation at time of enrollment. Remdesivir did not result in significant reduction in SARS-CoV-2 viral load in nasopharyngeal, oropharyngeal, and sputum samples. Remdesivir was discontinued in 18 pts (12%) because of adverse effects. Note: Enrollment was terminated before the pre-specified treatment duration is 5 days; if pt does not demonstrate clinical improvement, treatment may be extended for up to 5 additional days (i.e., up to a total treatment duration of 10 days). For those requiring invasive mechanical ventilation and/or ECMO, recommended total treatment duration is 10 days. Emergency use authorization (EUA) remdesivir dosage and duration of treatment recommended for hospitalized children weighing 3.5 to less than 40 kg (using the lyophilized powder formulation only): Loading dose of 5 mg/kg by IV infusion on day 1, followed by maintenance doses of 2.5 mg/kg by IV infusion once daily from day 2. For pts not requiring invasive mechanical ventilation and/or ECMO, recommended total treatment duration is 5 days, if pt does not demonstrate clinical improvement.</td>

**Drug(s)**  | **AHFS Class** | **Rationale** | **Trials or Clinical Experience** | **Dosage** | **Comments**  
--- | --- | --- | --- | --- | ---  
Remdesivir |  | Pharmacokinetic data available from evaluations for Ebola  
number of pts was attained (lack of available pts); trial was insufficiently powered to detect assumed differences in clinical outcome.  
**Phase 3 randomized, open-label trial in hospitalized pts with severe COVID-19 (NCT04292899; GS-US-540-5773; SIMPLE-Severe) sponsored by the manufacturer (Gilead): Initial study protocol was designed to evaluate safety and antiviral activity of 5- and 10-day regimens of remdesivir (200 mg IV on day 1, followed by 100 mg IV once daily for total of 5 or 10 days) in conjunction with standard of care in adults with severe COVID-19 not receiving mechanical ventilation at study entry; protocol was subsequently modified to include pts 12 years of age or older, add an extension phase, and include a cohort of pts receiving mechanical ventilation.**  
**Data for the initial 397 pts not requiring mechanical ventilation at study entry (200 received a 5-day regimen and 197 received a 10-day regimen) indicate similar clinical improvement with both treatment durations after adjusting for baseline clinical status. Pt demographics and clinical characteristics at baseline generally were similar in both groups, although the 10-day group included a higher percentage of pts in the most severe disease categories and a higher proportion of men (who are known to have worse COVID-19 outcomes than women); median duration of symptoms before first dose of remdesivir was similar in both groups (8 or 9 days). At day 14, 129/200 pts (65%) in the 5-day group and 106/197 pts (54%) in the 10-day group achieved clinical improvement (defined as an improvement of at least 2 points from baseline on a 7-point ordinal scale). After adjusting for baseline imbalances in disease severity, data indicate that clinical status at day 14, time to clinical improvement, recovery, and death (from any cause) were similar in both groups. Although eligibility criteria according to the initial study protocol excluded pts receiving invasive mechanical ventilation, 4 pts in the 5-day group and 9 pts in the 10-day group were receiving invasive mechanical ventilation or ECMO (need improvement, treatment may be extended for up to 5 additional days (i.e., up to a total treatment duration of 10 days).**  
For those requiring invasive mechanical ventilation and/or ECMO, recommended total treatment duration is 10 days.  
**NIH COVID-19 Treatment Guidelines Panel-recommended duration of remdesivir treatment when supplies are limited: The NIH panel recommends that hospitalized pts who require supplemental oxygen, but are not on high-flow oxygen, noninvasive ventilation, mechanical ventilation, or ECMO, receive remdesivir for a duration of 5 days or until hospital discharge, whichever comes first. If the pt progresses to requiring high-flow oxygen, noninvasive ventilation, mechanical ventilation, or ECMO during such treatment, the panel recommends that the remdesivir course be completed. The panel states that there are insufficient data on the optimal duration of remdesivir treatment for pts who have not shown clinical improvement after a 5-day regimen; some experts would extend the total duration of remdesivir treatment to up to 10 days in these patients.**  
**Phase 3 trial in adults and children ≥12 years of age with severe COVID-19 (NCT04292899; SIMPLE-Severe): 200 mg IV on day 1, then 100 mg IV daily on days 2-5 (arm 1) or 200 mg IV on day 1, then 100 mg IV daily on days 2-10 (extension arms that include pts who are or are not receiving mechanical ventilation).**  
**Phase 3 trial in adults and children ≥12 years of age with moderate COVID-19 (NCT04292730; SIMPLE-Moderate): 200 mg IV on day 1, then 100 mg IV daily on days 2-5 (arm 1) or 200 mg IV on day 1, then 100 mg IV daily on days 2-10 (arm 2).**  
**NIH panel states that they cannot make a recommendation either for or against initiating remdesivir in pts who require high-flow oxygen, noninvasive ventilation, mechanical ventilation, or ECMO because efficacy in this pt population has been demonstrated. (For recommendations on treatment duration in such pts, see Dosage.) The NIH panel states that they cannot make a recommendation either for or against initiating remdesivir in pts who require high-flow oxygen, noninvasive ventilation, mechanical ventilation, or ECMO because of uncertainty regarding whether initiating remdesivir in such pts confers clinical benefit. The panel states that these recommendations for prioritizing use of remdesivir are largely based on data from the phase 3 adaptive trial (NCT04280705; ACTT-1) in hospitalized adults with COVID-19 indicating that the benefit of remdesivir treatment was most apparent in pts who required supplemental oxygen, but did not require high-flow oxygen, noninvasive or mechanical ventilation, or ECMO at baseline. (See Trials or Clinical Experience.)**  
The NIH panel states that data are insufficient to recommend either for or against use of remdesivir for the treatment of mild or moderate COVID-19.**  
healthcare facilities and healthcare providers administering remdesivir comply with certain mandatory record keeping and reporting requirements (including adverse event reporting to FDA MedWatch). Consult the EUA fact sheet for healthcare providers, and EUA fact sheet for patients and parents/caregivers for additional information.

</table>

**Comparative analysis of data from phase 3 SIMPLE-Severe trial and real-world retrospective cohort of patients:** The manufacturer announced results of an analysis that compared data for 312 hospitalized pts with severe COVID-19 who received remdesivir in this randomized, open-label trial with a retrospective cohort of 818 pts with similar baseline characteristics and disease severity who received standard of care treatment (without remdesivir) during the same time period. More than 90% of pts in both groups were enrolled at North American trial sites and the rest were enrolled at European or Asian trial sites. Clinical recovery (improvement in clinical status based on a 7-point ordinal scale) and mortality rate for these 2 groups were compared. By day 14, recovery was reported in 74.4% of pts treated with remdesivir and 59% of pts in the retrospective cohort treated with standard of care and the mortality rate was 7.6 and 12.5%, respectively. **Subgroup analyses of data from Phase 3 SIMPLE-Severe trial:** The manufacturer announced results of subgroup analyses of 229 hospitalized pts with severe COVID-19.
who received remdesivir in this randomized, open-label trial and were enrolled at US trial sites. Clinical improvement was defined as a 2-point or greater improvement on a 7-point ordinal scale. At day 14, the rate of clinical improvement was 84% in black pts (n=43), 76% in Hispanic white pts (n=17), 67% in Asian pts (n=18), 67% in non-Hispanic white pts (n=119), and 63% in pts who did not identify with any of these groups (n=32). An analysis of 397 pts who were enrolled globally indicated that black race, age less than 65 years, treatment outside of Italy, and requirement of only low-flow oxygen support or room air at baseline were factors significantly associated with clinical improvement of at least 2 points on day 14. Another subgroup analysis was performed to evaluate outcomes in pts who received concomitant therapy with remdesivir and hydroxychloroquine vs those who received only remdesivir. At a median follow-up of 14 days, the rates and likelihood of recovery were lower in those treated with both drugs (57%) compared with those treated with remdesivir alone (69%). Although concomitant hydroxychloroquine was not associated with increased mortality at 14 days, the overall rate of adverse effects was higher and, after adjusting for baseline variables, the incidence of grade 3-4 adverse events was significantly higher in those treated with both drugs.

**Phase 3 randomized, open-label trial in hospitalized pts with moderate COVID-19 (NCT04292730; GS-US-540-5774; SIMPLE-Moderate) sponsored by the manufacturer (Gilead):** Initial study protocol was designed to evaluate safety and antiviral activity of 5- and 10-day regimens of remdesivir (200 mg IV on day 1, followed by 100 mg IV once daily for total of 5 or 10 days) in conjunction with standard of care compared with standard care alone in adults with moderate COVID-19 (i.e., hospitalized with evidence of pulmonary infiltrates and SpO₂ >94% on room air); protocol was subsequently modified to change the primary end point to clinical status on day 11 based on a 7-point ordinal scale,
include pts 12 years of age or older, and add an extension phase to include additional pts. Data for the initial group of adults who received a 5-day regimen of remdesivir with standard care (n=191), 10-day regimen of the drug with standard care (n=193), or standard care alone (n=200) have been published. At day 11, 70, 65, or 61% of pts in the 5-day, 10-day, or standard of care alone group, respectively, had clinical improvement based on at least a 2-point improvement from baseline on a 7-point ordinal scale. Pts in the 5-day remdesivir group had statistically significant higher odds of a better clinical status distribution on the 7-point scale on day 11 than those receiving standard care (odds ratio: 1.65) but the difference was of uncertain clinical importance; the difference in clinical status distribution between pts in the 10-day remdesivir group and the standard care group was not statistically significant. At day 11, 4 deaths were reported in the standard care alone group compared with none in the 5-day group and 2 in the 10-day group. There were no significant differences between the 5- or 10-day remdesivir groups and standard care group for any of the exploratory end points at day 11 (time to 2-point or greater improvement in clinical status, time to 1-point or greater improvement in clinical status, time to recovery, time to modified recovery, time to discontinuation of oxygen support). At day 14, the clinical status of pts in the 5-day and 10-day remdesivir groups was significantly different than that of the standard care group. Note: Effect of remdesivir on SARS-CoV-2 viral load was not assessed. Limitations of this study include the open-label design and use of an ordinal scale to evaluate outcomes that was not ideal for detecting differences in pts with moderate COVID-19.

Phase 3 adaptive, randomized, double-blind, placebo-controlled trial (NCT04280705; NIAID Adaptive COVID-19 Treatment Trial 1 [ACTT-1]) in hospitalized adults with COVID-19: 1063 pts were randomized 1:1 to receive remdesivir (200 mg IV on day 1, then 100 mg IV once daily on days 2-10) or standard care.

All pts received supportive care according to the standard of care for the trial site hospital. Baseline demographics and clinical characteristics (e.g., age, disease severity, comorbidities at study enrollment, time to initiation of treatment after symptom onset) were similar in both groups. Overall, 88.7% of pts had severe disease at study enrollment and the median time from symptom onset to randomization was 9 days (range: 6-13 days). Preliminary data analysis that included 1059 pts (538 randomized to remdesivir and 521 randomized to placebo) indicated shorter median time to recovery in the remdesivir group (11 days) vs the placebo group (15 days) and suggested that remdesivir treatment may have provided a survival benefit (Kaplan-Meier estimates of mortality by day 14 were 7.1% in the remdesivir group vs 11.9% in the placebo group). Based on preliminary subgroup analyses, the benefit of remdesivir was most apparent in the 421 pts who required supplemental oxygen but were not on mechanical ventilation or ECMO at baseline (recovery rate ratio 1.47). The recovery rate ratio in the subgroup of 272 pts on mechanical ventilation or ECMO at enrollment was 0.95. However, additional data analyses are needed and are ongoing regarding outcomes in these subgroups.

Data from the manufacturer's compassionate use program (adults): Preliminary data are available for a cohort of 53 adults from multiple sites in the US, Italy, Japan, and other countries who were hospitalized with severe COVID-19 and received treatment with remdesivir; 40 pts received the full 10-day regimen (200 mg IV on day 1, then 100 mg IV on days 2-10), 10 pts received 5-9 days and 3 pts received less than 5 days of treatment with the drug. At baseline, 30 pts (57%) were receiving mechanical ventilation and 4 (18%) were receiving extracorporeal membrane oxygenation (ECMO). Over a median follow-up of 18 days after first dose, 36 pts (68%) showed clinical improvement based on oxygen-support status and 8 pts (15%) worsened.

</tbody>
</table>

Data from the manufacturer’s compassionate use program (pediatric pts): The manufacturer announced that preliminary data are available for 77 pediatric pts treated with remdesivir in the compassionate use program. Analysis of day-28 data indicated that 73% of these pediatric pts were discharged from the hospital, 12% remained hospitalized but on ambient air, and 4% had died. There were 39 critically ill pediatric pts who required invasive mechanical ventilation at baseline and 80% of these pts recovered; there were 38 pediatric pts who did not require invasive ventilation and 87% of these pts recovered. No new safety signals were identified for remdesivir in this population. |

Data from the manufacturer’s compassionate use program (pregnant and postpartum women): The manufacturer announced that preliminary data are available for 86 pregnant and postpartum women treated with remdesivir in the compassionate use program. Analysis of data for these pts (median age 33 years) indicated that 96% of the pregnant women and 89% of the postpartum women achieved improvement in oxygen support levels. Those with

| COVID-19 Treatment Trial (ACTT) is evaluating possible benefits of using baricitinib (a Janus kinase [JAK] inhibitor) in conjunction with remdesivir in hospitalized adults with laboratory-confirmed SARS-CoV-2 infection and evidence of lung involvement (abnormal chest x-rays, SpO\textsubscript{2} of 94% or lower on room air, or requiring supplemental oxygen, mechanical ventilation, or ECMO). Pts will be randomized 1:1 to receive remdesivir (200 mg IV on day 1, then 100 mg IV once daily for the duration of hospitalization up to 10 days total) with either oral baricitinib (4 mg once daily for the duration of hospitalization up to 14 days total) or placebo.  

Phase 3 adaptive, randomized, double-blind trial to compare a regimen of remdesivir alone vs a regimen of remdesivir with interferon beta-1a (NCT04492475; ACTT3): This iteration of NIAID's Adaptive COVID-19 Treatment Trial (ACTT) will evaluate possible benefits of using interferon beta-1a in conjunction with remdesivir in hospitalized adults with laboratory-confirmed SARS-CoV-2 infection.  

Inclusion criteria include evidence of lung involvement (radiographic infiltrates, SpO\textsubscript{2} of 94% or lower on room air, or requiring supplemental oxygen or mechanical ventilation); exclusion criteria include need for ECMO, prior treatment with ≥3 doses of remdesivir, treatment with any interferon preparation within the previous 2 weeks, prior treatment with convalescent plasma or IGIV or various other drugs used for management of COVID-19. Pts will be randomized 1:1 to receive remdesivir (200 mg IV on day 1, then 100 mg IV once daily for the duration of hospitalization up to 10 days total) with either sub-Q interferon beta-1a (44 mcg once daily on days 1, 3, 5, and 7 during hospitalization for a total of 4 doses) or placebo.  

Randomized, double-blind trial to compare a regimen of remdesivir alone vs a regimen of remdesivir with tocilizumab (NCT04409262; REMDACTA): This trial will evaluate possible benefits of using | | | | | |

**Drug(s)** | **AHFS Class** | **Rationale** | **Trials or Clinical Experience** | **Dosage** | **Comments**
--- | --- | --- | --- | --- | ---
Anakinra (Kineret<sup>®</sup>) | 92:36 Disease-modifying Anti-rheumatic Drug | Recombinant human interleukin-1 (IL-1) receptor antagonist<sup>1</sup> | Currently no known published prospective clinical trial evidence supporting efficacy or safety of anakinra for treatment of COVID-19<sup>7</sup> | Various dosage regimens are being studied<sup>1,8</sup> | NIH COVID-19 Treatment Guidelines Panel states that there are insufficient clinical data to recommend either for or against use of anakinra in the treatment of COVID-19<sup>7</sup>

**France:** A cohort study (Ana-COVID) included a prospective cohort of 52 adults with severe COVID-19 treated with anakinra plus standard of care and a historical comparison group of 44 patients who received standard and supportive care at Groupe Hospitalier Paris Saint-Joseph. Inclusion criteria included severe COVID-19-associated bilateral pneumonia on chest x-ray or lung CT scan, laboratory-confirmed SARS-CoV-2 or typical lung infiltrates on a lung CT scan, and an oxygen saturation of ≤93% under oxygen 2 L/min or deterioration (saturation 93% under oxygen 3 L/min with loss of 3% oxygen saturation in ambient air over previous 24 hours). Anakinra was given subcutaneously in a dosage of 100 mg twice daily on days 1–3, then 100 mg once daily from day 4–10<sup>5,9</sup>. A retrospective cohort study in Italy compared high-dose anakinra by IV infusion (5 mg/kg twice daily) and low-dose anakinra (100 mg twice daily) given subcutaneously<sup>10</sup> (Note: Anakinra is approved only for subcutaneous administration in the U.S.)<sup>1,7</sup>

**France:** A small case series (9 patients) of open-label anakinra treatment in hospitalized (non-ICU) adults with moderate to severe COVID-19 pneumonia has been published with encouraging results<sup>8</sup>

**Italy:** Retrospective cohort study (part of NCT04318366) with high- or low-dose anakinra in adults with COVID-19, moderate to severe acute respiratory distress syndrome (ARDS), and hyperinflammation (defined as elevated serum C-reactive protein [CRP] and/or ferritin levels) managed with non-invasive ventilation outside of the ICU at a

Milan hospital. Patients received standard therapy (hydroxychloroquine and lopinavir/ritonavir) and either high-dose anakinra (5 mg/kg twice daily by IV infusion for a median of 9 days followed by daily low-dose subcutaneous administration [100 mg twice daily] for 3 additional days to prevent relapse) or low-dose anakinra (100 mg twice daily subcutaneously) and were compared with a historical cohort of patients who did not receive anakinra. At 21 days, high-dose anakinra was associated with reduced CRP levels and progressive improvement in respiratory function in 21 of 29 (72%) of patients; 5 patients (17%) were placed on mechanical ventilation and 3 patients (10%) died. High-dose IV anakinra appeared to be relatively well tolerated. Anakinra was discontinued in the low-dose subcutaneous anakinra group after 7 days because of a lack of improvement in CRP levels and clinical status. In the standard treatment alone group (retrospective cohort), 8 out of 16 patients (50%) showed respiratory improvement at 21 days; 1 patient (6%) was placed on mechanical ventilation and 7 patients (44%) died.

**Italy:** Phase 3 randomized, open-label, multicenter trial (NCT04324021) initiated by the manufacturer (Swedish Orphan Biovitrum) to evaluate efficacy and safety of anakinra or emapalumab with standard of care in reducing hyperinflammation and respiratory distress in patients with COVID-19 is recruiting.

Numerous other clinical trials evaluating anakinra in the treatment of COVID-19 are planned or under way, mainly in Europe.

### IV ascorbic acid:
- **Phase 3 randomized, blind, placebo-controlled trial (NCT03680274; LOVIT) evaluating effect of high-dose IV ascorbic acid on mortality and persistent organ dysfunction in septic ICU patients (including COVID-19 patients); other clinical trials of high-dose IV ascorbic acid for treatment of COVID-19 registered, including:**
  - NCT04264533
  - NCT04323514
  - NCT04363216

**IV ascorbic acid:** Various dosages of IV ascorbic acid used in COVID-19 studies; 50 mg/kg every 6 hours for 4 days used in NCT03680274 and NCT04401150.

Various dosages of IV ascorbic acid used in sepsis studies; 50 mg/kg every 6 hours for up to 10 days used in VITAMINS study.

Current clinical trial data not specific to COVID-19; additional study needed.

NIH COVID-19 Treatment Guidelines Panel states that there are insufficient data to recommend either for or against use of ascorbic acid for the treatment of COVID-19 in critically ill patients. The panel states that there are no completed controlled trials of ascorbic acid in patients with COVID-19, and the available observational data are sparse and

<td>Azithromycin</td>
<td>8:12.12</td>
<td>Macrolides</td>
<td>Antibacterial with some in vitro activity against some viruses (e.g., influenza A H1N1, Zika) 1,3</td>
<td>Adjunctive therapy in certain respiratory viral infections: Although contradictory results reported, some evidence of beneficial immunomodulatory or anti-inflammatory effects when used in pts with some viral infections (e.g., influenza). 10,12. However, in a retrospective cohort study in critically ill pts with laboratory-confirmed COVID-19, 13 current data are insufficient to establish pros and cons of adjunctive use of azithromycin in the management of COVID-19, including use for empiric antibacterial coverage for suspected secondary bacterial pneumonia. 22</td>
<td>Current data are insufficient to establish pros and cons of adjunctive use of azithromycin in the management of COVID-19, including use for empiric antibacterial coverage for suspected secondary bacterial pneumonia. 22</td>
</tr>
</tbody>
</table>

### Trials or Clinical Experience

- **NCT04401150 (LOVIT-COVID)**
- **NCT04395768**
- **Oral ascorbic acid:** Randomized, open-label study (NCT04342728; COVIDAtoZ) initiated to evaluate oral ascorbic acid (8 g daily), zinc, or both in combination in symptomatic outpatients receiving a positive COVID-19 test result; other clinical trials of outpatient oral ascorbic acid treatment registered, including NCT04395768 1

  - Included at lower dosages as an active or placebo-equivalent comparator (control) in other COVID-19 prevention or treatment studies 1

  - Included as a component of some hydroxychloroquine-based combination regimens being studied for prevention or treatment of COVID-19 3

### Other infections:

- **Sepsis:** Meta-analysis of several small studies suggested beneficial effects from IV ascorbic acid; however, primary end points not improved in CITRIS-ALI study (NCT02106975) in patients with sepsis and ARDS or in VITAMINS study (NCT03333278) in patients with septic shock; additional studies under way 1,6,8-10

  - High circulating vitamin C concentrations may affect accuracy of point-of-care glucometers. 12

  - NIH COVID-19 Treatment Guidelines Panel also states that there are insufficient data to recommend either for or against use of ascorbic acid for the treatment of COVID-19 in noncritically ill patients. The panel states that there is no compelling reason to use ascorbic acid in this setting since patients who are not critically ill with COVID-19 are less likely to experience oxidative stress or severe inflammation. 12

- **Pneumonia:** Limited study data available regarding ascorbic acid (oral) in hospitalized patients with pneumonia 1,3

  - Common cold: Effect of oral supplementation studied extensively; decreases duration of symptoms, may decrease incidence of common cold in individuals under heavy physical stress but not in overall population 2,3

### Dosage*

- **Oral ascorbic acid:** NCT04342728: Oral ascorbic acid dosage of 8 g daily, given in 2 or 3 divided doses 1

- **NCT04395768 (outpatients):** Ascorbic acid 1 g orally 3 times daily for 7 days following initial 200-200 mg/kg IV dose

  - Note: May interfere with laboratory tests based on oxidation-reduction reactions (e.g., blood and urine glucose testing, nitrite and bilirubin concentrations, leukocyte counts). 11

  - Manufacturer states to delay oxidation-reduction reaction-based tests until 24 hours after infusion, if possible 11

<tr>
<td></td>
<td></td>
<td>recommended in all pts with confirmed COVID-19-related pneumonia. If bacterial pneumonia or sepsis is strongly suspected or confirmed, empiric antibacterial treatment should be administered. Although data are limited, bacterial pathogens in COVID-19 pts with community-acquired pneumonia (CAP) are likely the same as those seen in other pts with CAP. Therefore, if antibacterial coverage for CAP is indicated in COVID-19 pts, the usually recommended regimens for empiric treatment of CAP should be used. Antimicrobial stewardship policies should be used to guide appropriate use of antibacterials in COVID-19 pts. Data from randomized, controlled clinical trials are insufficient to date to draw conclusions regarding possible benefits of using a combined regimen of hydroxychloroquine and azithromycin for the treatment of COVID-19; there are data indicating that combined use of azithromycin and chloroquine or hydroxychloroquine may be associated with an increased risk of adverse cardiac effects. NIH COVID-19 Treatment Guidelines Panel recommends against the use of any combination regimen of hydroxychloroquine and azithromycin for the treatment of COVID-19, except in the context of a clinical trial, because of the potential for toxicities. (See Hydroxychloroquine in this Evidence Table.) IDSA recommends against use of any combination regimen of hydroxychloroquine and azithromycin for the treatment of COVID-19 in hospitalized pts. Because azithromycin and 4-aminoquinolines (hydroxychloroquine, chloroquine) are independently associated with QT prolongation, caution is advised if considering use of azithromycin with one of these drugs in pts with</td>

<td>Interim analysis (not peer reviewed) of a single-center, randomized, double-blind, placebo-controlled trial in hospitalized adults with moderate to severe, RT-PCR-confirmed COVID-19 with pneumonia (not requiring ICU admission): Analysis of first 38 patients randomized 1:1 to colchicine or placebo indicated shorter duration of oxygen supplementation (3 vs 7 days) and shorter hospital stay (6 vs 8.5 days) in colchicine group vs placebo group. One patient in each group required ICU admission. Median duration of symptoms prior to treatment was 9 days (colchicine group) or 7 days (placebo group). Colchicine dosage was 0.5 mg 3 times daily for 5 days, then 0.5 mg twice daily for 5 days (initial dose was 1 mg if body weight ≥ 80 kg); dosage was reduced for renal impairment. Standard concomitant treatment included 7-day azithromycin regimen, up to 10-day hydroxychloroquine regimen, and heparin with or without methylprednisolone (depending on oxygenation status). 18 Phase 3, randomized, double-blind, placebo-controlled study (NCT04322682; COL-CORONA) initiated in adults ≥ 40 years of age with COVID-19 and at least one high-risk criterion to evaluate effect of colchicine on mortality, hospitalization rate, and need for mechanical ventilation; study excludes enrollment of currently hospitalized patients; enrollment target is approximately 6000 pts 1 Other registered randomized, parallel-group studies are evaluating the effects of colchicine on various outcome measures (e.g., mortality, markers of myocardial damage, clinical status, need for mechanical ventilation, duration of hospitalization) in patients with COVID-19: NCT04322565, NCT04328480, NCT04350320, NCT04355143, NCT04392141, NCT04375202, NCT04360980, NCT04367168, NCT04403243, NCT04363437, NCT04416334, NCT04324463 2,3</td>

<td>Corticosteroids</td>
<td>68:04 Adrenals</td>
<td>Potent anti-inflammatory and antifibrotic properties; use of corticosteroids may prevent an extended cytokine response and may accelerate resolution of pulmonary and systemic inflammation in pneumonia. 1, 9 Evidence suggests that cytokine storm, a hyperinflammatory state resembling secondary hemophagocytic lymphohistiocytosis (HLH), is a contributing factor in COVID-19-associated mortality. 8, 18 Immunosuppression from corticosteroids has been proposed as a treatment option for such hyperinflammation. 18 May improve dysregulated immune response caused by sepsis (possible complication of infection with COVID-19) and increase BP when low. 4, 11</td>
<td>Observational studies in other respiratory infections (e.g., SARS, MERS, influenza): In these studies, corticosteroid use was associated with no survival benefit and possible harm (e.g., delayed viral clearance, avascular necrosis, psychosis, diabetes). 1, 24, 25 Randomized controlled studies in acute respiratory distress syndrome (ARDS): Systemic corticosteroid therapy has been studied in several randomized controlled studies for the treatment of ARDS; overall evidence is low to moderate in quality and most studies were performed prior to widespread implementation of lung protection strategies. 5, 6, 9, 14, 17 Dexamethasone randomized, controlled, unblinded study in hospitalized patients with ARDS (DEXA-ARDS): The effects of dexamethasone in conjunction with conventional care were evaluated in hospitalized patients with moderate-to-severe ARDS receiving lung-protective mechanical ventilation. 17 Treatment with IV dexamethasone at a dosage of 20 mg once daily on days 1-5, followed by 10 mg once daily on days 6-10 resulted in reduced duration of mechanical ventilation and reduced overall mortality (i.e., 15% increase in 60-day survival) compared with conventional treatment alone. 17 Based on results of this study, a randomized controlled open-label trial (NCT04325061; DEXA-COVID19) has been initiated to specifically evaluate the use of IV dexamethasone at the same dosage of 20 mg once daily on days 1-5, followed by 10 mg once daily on days 6-10 in patients with ARDS due to COVID-19. 21 Randomized, controlled, open-label, adaptive trial with a Dexamethasone arm (NCT04381936; RECOVERY): This trial was conducted to evaluate the effect of potential treatments (including low-dose dexamethasone) on all-cause mortality in hospitalized patients with COVID-19. The study enrolled patients with suspected or confirmed COVID-19 from 176 hospitals in the UK. In the dexamethasone treatment arm, 2,104 patients were randomized to receive **The NIH COVID-19 Treatment Guidelines Panel recommends an IV or oral Dexamethasone dosage of 6 mg daily for up to 10 days or until hospital discharge, whichever comes first, in COVID-19 patients requiring mechanical ventilation and in patients who require supplemental oxygen but who are not mechanically ventilated. Although the clinical benefits of other corticosteroids (e.g., hydrocortisone, methylprednisolone, prednisone) are not clear, the panel recommends using total daily dosages of these drugs equivalent to dexamethasone 6 mg (IV or oral) as follows: Hydrocortisone 160 mg, Methylprednisolone 32 mg, or Prednisone 40 mg. Based on half-life and duration of action, frequency of administration varies among these corticosteroids. Dexamethasone is long-acting and administered once daily. Methylprednisolone and Prednisone are intermediate-acting and administered once daily or in 2 divided doses daily. Hydrocortisone is short-acting and administered in 2-4 divided doses daily. 24 Regimens used in early cases of COVID-19 in China were typically methylprednisolone 40-80 mg IV daily for a course of 3-6 days. Some experts suggest that equivalent dosages of dexamethasone (i.e., 7-15 mg daily, typically 10 mg daily) may have an advantage of producing less fluid retention, since dexamethasone has less mineralocorticoid activity. 8 This dosage of dexamethasone is consistent with those used in the DEXA-ARDS trial. 8, 17 However, lower dosages of dexamethasone (i.e., 6 mg once daily for 10 days) were used in the RECOVERY trial. 22, 23 **Higher dosages of IV Dexamethasone (i.e., 20 mg once daily for 5 days followed by 10 mg once daily for an additional 5 days or until ICU discharge, whichever comes first) in patients with COVID-19 who are receiving mechanical ventilation or in those who require supplemental oxygen but are not on mechanical ventilation. The panel recommends against the use of dexamethasone in COVID-19 patients who do not require supplemental oxygen. 24</td>
<td>Data on the use of corticosteroids in COVID-19 are limited. 3, 5, 7, 24, 25 The benefits and risks of corticosteroid therapy should be carefully weighed before use in patients with COVID-19. 1, 7 NIH, CDC, WHO, IDSA, and other experts have issued guidelines for the use of corticosteroids in patients with COVID-19 based on the currently available information. Recommendations are made according to the severity of illness, indications, and underlying medical conditions and should be considered on a case-by-case basis. 1, 2, 8, 12, 24, 25 Non-critical patients: Corticosteroids generally should not be used in the treatment of early or mild disease since the drugs can inhibit immune response, reduce pathogen clearance, and increase viral shedding. 1, 8, 24 Critically ill patients: The Surviving Sepsis Campaign COVID-19 subcommittee (a joint initiative of the Society of Critical Care Medicine and the European Society of Intensive Care Medicine) recommends against the routine use of systemic corticosteroids in mechanically ventilated adults with COVID-19 and respiratory failure (without ARDS). 12 However, these experts generally support a weak recommendation to use low-dose, short-duration systemic corticosteroids in the sickest patients with COVID-19 and ARDS. 12 Based on preliminary findings from the RECOVERY trial, the NIH COVID-19 Treatment Guidelines Panel recommends the use of dexamethasone (6 mg daily for up to 10 days or until hospital discharge, whichever comes first) in patients with COVID-19 who are receiving mechanical ventilation or in those who require supplemental oxygen but are not on mechanical ventilation. The panel recommends against the use of dexamethasone in COVID-19 patients who do not require supplemental oxygen. 24</td>

Dexamethasone (6 mg once daily orally or IV for up to 10 days) plus standard care and 4321 patients were randomized to receive standard care alone. Preliminary data analysis indicates that overall 28-day mortality was reduced in patients receiving dexamethasone compared with those receiving standard care alone with the greatest benefit observed in patients requiring mechanical ventilation at enrollment. Overall, 22.9% of patients receiving dexamethasone and 25.7% of those receiving standard care died within 28 days of study enrollment. In patients receiving dexamethasone, the incidence of death was lower than that in the standard care group among those receiving invasive mechanical ventilation (29.3 vs 41.4%) and among those receiving supplemental oxygen without invasive mechanical ventilation (23.3 vs 26.2%). However, no survival benefit was observed with dexamethasone and there was a possibility of harm in patients who did not require respiratory support at enrollment; the incidence of death in such patients receiving dexamethasone compared with standard care was 17.8 vs 14%, respectively. Dexamethasone was associated with a reduction in 28-day mortality among patients with symptoms for >7 days compared with those having more recent symptom onset. Dexamethasone treatment also was associated with a shorter duration of hospitalization and a greater probability of discharge within 28 days with the greatest effect observed among patients receiving invasive mechanical ventilation at baseline.

**Note:** Data regarding potential adverse effects, efficacy in combination with other treatments (e.g., remdesivir), and efficacy in other patient populations (e.g., pediatric patients and pregnant women) not available to date.

**Dexamethasone randomized, controlled, open-label, multicenter study (NCT04327401; CoDEX):** This trial was conducted to determine whether IV dexamethasone increases the number of ventilator-free days among patients with COVID-19-associated ARDS. The study enrolled adults with COVID-19 and moderate or severe discharge, whichever came first) were used in the CoDEX trial in patients with COVID-19 and moderate or severe ARDS.

**Continuous IV infusion of Hydrocortisone** 200 mg/day for 7 days, followed by 100 mg/day for 4 days, and then 50 mg/day for 3 days (total of 14 days) was used in the CAPE COVID study. If a patient’s respiratory and general status sufficiently improved by day 4, a shorter treatment regimen of Hydrocortisone was used at a dosage of 200 mg/day for 4 days followed by 100 mg/day for 2 days and then 50 mg/day for 2 days (total of 8 days).

**A fixed dosage of IV Hydrocortisone** (50 or 100 mg every 6 hours for 7 days) or a shock-dependent regimen of IV hydrocortisone (50 mg every 6 hours for up to 28 days in the presence of clinically evident shock) was used in the REMAP-CAP study.

The NIH guidelines panel also states that prolonged use of systemic corticosteroids in patients with COVID-19 may increase the risk of reactivation of latent infections (e.g., hepatitis B virus [HBV], herpesvirus, strongyloidiasis, tuberculosis). The risk of reactivation of latent infections following a 10-day course of dexamethasone (6 mg once daily) is not well established. When initiating dexamethasone in patients with COVID-19, appropriate screening and treatment to reduce the risk of Strongyloides hyperinfection in those at high risk of strongyloidiasis (e.g., patients from tropical, subtropical, or warm, temperate regions or those engaged in agricultural activities) or fulminant reactivations of HBV should be considered.

The NIH guidelines panel also states that it is not known at this time whether other corticosteroids will have a similar benefit as dexamethasone. However, if dexamethasone is not available, the panel recommends using alternative corticosteroids (e.g., hydrocortisone, methylprednisolone, prednisone).

IDSA suggests the use of corticosteroids over no corticosteroid therapy in hospitalized patients with severe COVID-19 (i.e., defined as patients with SpO₂<94% on room air and those who require supplemental oxygen, mechanical ventilation, or ECMO). These experts suggest the use of dexamethasone 6 mg orally or IV daily for 10 days or until hospital discharge, whichever comes first, or substitution of equivalent daily dosages of other corticosteroids (e.g., methylprednisolone 32 mg, prednisone 40 mg) if dexamethasone is unavailable. However, IDSA suggests against using corticosteroids in hospitalized patients with COVID-19 without hypoxemia requiring supplemental oxygen.

Cytokine storm: There is no well-established or evidence-based treatment for cytokine storm in patients with COVID-19. However, some experts...
### ARDS who were receiving mechanical ventilation from 41 ICUs in Brazil. In the dexamethasone treatment arm, 151 patients were randomized to receive dexamethasone (20 mg IV once daily for 5 days followed by 10 mg IV once daily for another 5 days or until ICU discharge) plus standard care; 148 patients were randomized to receive standard care alone. The primary study end point was ventilator-free days (defined as number of days alive and free from mechanical ventilation) during the first 28 days. Preliminary data analysis indicates that use of IV dexamethasone plus standard care was associated with a higher mean number of ventilator-free days (6.6 days) compared with those receiving standard care alone (4 days). Although there was no significant difference in all-cause mortality at 28 days between the treatment groups, the trial was terminated early after results of the RECOVERY trial became available and, therefore, likely underpowered to determine secondary outcomes such as mortality. Dexamethasone was not associated with an increased risk of adverse effects in this study population of critically ill COVID-19 patients. **Hydrocortisone randomized, double-blind sequential trial (NCT02517489; CAPE COVID):** This trial was conducted to evaluate the effect of low-dose hydrocortisone compared with placebo on treatment failure in critically ill patients with COVID-19-related acute respiratory failure. The study enrolled adults with COVID-19-associated acute respiratory failure from 9 ICUs in France. In the hydrocortisone treatment arm, 76 patients received a continuous IV infusion of hydrocortisone at an initial dosage of 200 mg/day for 7 days followed by 100 mg/day for 4 days, and then 50 mg/day for 3 days (total of 14 days; some patients received a shorter regimen); 73 patients received placebo. The primary study end point was treatment failure (defined as death or persistent dependency on mechanical ventilation or high-flow oxygen therapy) on day 21. Treatment failure on day 21 occurred in 42.1% of patients in the hydrocortisone group compared with 49.9% in the placebo group. The study did not show a statistically significant difference in the primary endpoint, but it did suggest that use of more potent immunosuppression with corticosteroids may be beneficial in such patients. These experts suggest higher dosages of corticosteroids (e.g., IV methylprednisolone 60-125 mg every 6 hours for up to 3 days) followed by tapering of the dose when inflammatory markers (e.g., C-reactive protein levels) begin to decrease. **Septic shock:** The effect of corticosteroids in COVID-19 patients with sepsis or septic shock may be different than the effects seen in those with ARDS. The Surviving Sepsis Campaign and NIH suggest the use of low-dose corticosteroid therapy (e.g., hydrocortisone 200 mg daily as an IV infusion or intermittent doses) over no corticosteroid therapy in adults with COVID-19 and refractory shock. Randomized controlled studies evaluating use of corticosteroids (e.g., hydrocortisone, dexamethasone, methylprednisolone, prednisolone) in septic shock suggest a small, but uncertain mortality reduction. Clinicians considering corticosteroids for such patients with COVID-19 should balance the potential small reduction in mortality with potential effects of prolonged coronavirus shedding. If corticosteroids are prescribed, monitor and treat adverse effects including hyperglycemia, hypernatremia, and hypokalemia. **Patients receiving corticosteroid therapy for chronic conditions:** NIH states that oral corticosteroids used for the treatment of an underlying condition prior to COVID-19 infection (e.g., primary or secondary adrenal insufficiency, rheumatologic diseases) should not be discontinued. Supplemental or stress dosages of corticosteroids may be indicated on an individual basis in patients with such conditions. (See Corticosteroids [inhaled] in this Evidence Table for recommendations for use of inhaled corticosteroids in COVID-19 patients with asthma or COPD.)

---|---|---|---|---|---
Methylprednisolone, hydrocortisone, dexamethasone, methylprednisolone |  | 50.7% of patients in the placebo group. The difference between the treatment groups was not statistically significant; however, the study was discontinued early after results of the RECOVERY trial were announced and, therefore, likely underpowered to determine a statistically and clinically important difference in the primary outcome. 40**<br>****Hydrocortisone multicenter, ongoing, international open-label trial using a randomized, embedded multifactorial adaptive platform (NCT02735707; REMAP-CAP): This trial randomized patients to multiple interventions within multiple domains. In the COVID-19 corticosteroid domain, adults from 8 countries with suspected or confirmed COVID-19 following admission to an ICU for respiratory or cardiovascular organ support were randomized to receive a fixed 7-day regimen of IV hydrocortisone (50 or 100 mg every 6 hours), a shock-dependent regimen of IV hydrocortisone (50 mg every 6 hours when shock was clinically evident), or no hydrocortisone or other corticosteroid. The primary study end point was organ support-free days (defined as days alive and free of ICU-based respiratory or cardiovascular support) within 21 days. The 7-day fixed regimen and the shock-dependent regimen of hydrocortisone were associated with a 93 and 80% probability of benefit in terms of organ support-free days compared with no hydrocortisone. However, the trial was discontinued early after results of the RECOVERY trial were announced and no treatment strategy met the prespecified criteria for statistical superiority, precluding definitive conclusions. In addition, serious adverse effects were reported in 2.6% of patients in the study (4 patients receiving the fixed-dosing regimen and 5 patients receiving the shock-dependent regimen compared with 1 patient receiving no hydrocortisone). 41**<br>****Prospective meta-analysis of studies using systemic corticosteroids (i.e., dexamethasone, hydrocortisone, or methylprednisolone) from the WHO Rapid Evidence Appraisal for COVID-19**

Rheumatology experts, including members of the American College of Rheumatology COVID-19 Clinical Guidance Task Force, state that abrupt discontinuation of corticosteroid therapy in patients with rheumatologic diseases should be avoided regardless of COVID-19 exposure or infection status. These experts also state that if indicated, corticosteroids should be used at the lowest effective dosage to control manifestations, but also acknowledge that higher dosages may be necessary in the context of severe, vital organ-threatening rheumatologic disease even following COVID-19 exposure. 28-30

Endocrinology experts state that patients with primary or secondary adrenal insufficiency who are receiving prolonged corticosteroid therapy should follow usual steroid “sick day rules” since these individuals may not be able to mount a normal stress response in the event of COVID-19 infection. 19,26 If such individuals develop symptoms such as fever and a dry continuous cough, they should immediately double their daily oral corticosteroid dosage and continue with this regimen until the fever subsides. 19 These guidelines also apply to patients who are receiving prolonged therapy (>3 months) with corticosteroids for underlying inflammatory conditions, including asthma, allergy, and rheumatoid arthritis. 19 In such patients whose condition worsens or in those experiencing vomiting or diarrhea, treatment with parenteral corticosteroids may be necessary. 19,26 Administration of physiologic stress doses of corticosteroids (e.g., IV hydrocortisone 50-100 mg 3 times daily) and not pharmacologic doses should be considered in all cases to avoid potentially fatal adrenal failure. 19,20 Additional study is needed to determine the optimum corticosteroid stress dosage regimens in patients with COVID-19. 26,27 There is some evidence suggesting that continuous IV infusion of hydrocortisone (following an initial IV bolus dose) may

</table>
| Therapies (REACT) Working Group: This meta-analysis pooled data from 7 randomized clinical trials in 12 countries that evaluated the efficacy of corticosteroids in 1703 critically ill patients with COVID-19. The primary outcome was all-cause mortality up to 30 days after randomization to treatment. Administration of systemic corticosteroids was associated with lower all-cause mortality at 28 days compared with usual care or placebo (222 deaths among 678 patients who received corticosteroids and 425 deaths among 1025 patients who received usual care or placebo). The effect of corticosteroids on reduced mortality was observed in critically ill patients who were and were not receiving mechanical ventilation at randomization and also in patients from the RECOVERY trial who required supplemental oxygen with or without non-invasive ventilation but who were not receiving invasive mechanical ventilation at the time of randomization. The odds ratios for the association between corticosteroids and mortality were similar for dexamethasone and hydrocortisone. The optimal dosage and duration of corticosteroid treatment could not be determined from this analysis; however, there was no evidence suggesting that a higher dosage of corticosteroids was associated with greater benefit than a lower dosage. The authors also concluded that there was no suggestion of an increased risk of serious adverse effects associated with corticosteroid use.<sup>42</sup>

Methylprednisolone open-label, multicenter, randomized, controlled study (NCT04244591): This recently completed trial compared use of methylprednisolone in conjunction with standard care in patients with confirmed COVID-19 infection that progressed to acute respiratory failure; results have not yet been posted.<sup>23</sup>

Retrospective, observational study of systemic corticosteroid use in patients with COVID-19 from a New York hospital (Keller et al): Data are available for 1806 patients hospitalized with COVID-19 between Mar 11 and Apr 13, 2020. Patients included in the analysis were those treated with provide more stable circulating cortisol concentrations in patients with adrenal insufficiency and reduce the potentially harmful effects of peak and trough concentrations of cortisol on the immune system.<sup>26, 27</sup>

Pregnancy considerations: For pregnant women with COVID-19, the NIH COVID-19 Treatment Guidelines Panel states that a short course of corticosteroids that cross the placenta (i.e., betamethasone, dexamethasone) is routinely used for fetal benefit (e.g., to hasten fetal lung maturity). Given the potential benefit of decreased maternal mortality and the low risk of fetal adverse effects for this short course of corticosteroid therapy, the panel recommends the use of dexamethasone in pregnant women with COVID-19 who are receiving mechanical ventilation or in those who require supplemental oxygen but are not on mechanical ventilation.<sup>24</sup>

Pediatric considerations: The safety and efficacy of dexamethasone or other corticosteroids for COVID-19 treatment have not been sufficiently evaluated in pediatric patients. Importantly, the RECOVERY trial did not include a significant number of pediatric patients, and mortality rates are significantly lower for pediatric patients with COVID-19 than for adult patients with the disease. Therefore, results of this trial should be interpreted with caution for patients <18 years of age. The NIH COVID-19 Treatment Guidelines Panel states that use of dexamethasone may be beneficial in pediatric patients with respiratory disease due to COVID-19 who are receiving mechanical ventilation. Use of dexamethasone in patients who require other forms of supplemental oxygen support should be considered on an individual basis, and is generally not recommended for pediatric patients who require only low levels of oxygen support (i.e., nasal cannula only). Additional studies are needed to evaluate the use of corticosteroids for the

<td>systemic corticosteroids (e.g., dexamethasone, hydrocortisone, methylprednisolone, prednisone) within the first 48 hours of hospital admission (140 patients) and those not treated with corticosteroids (1666 patients) as the control group. Treatment and control groups were similar except that corticosteroid-treated patients were more likely to have a history of COPD, asthma, rheumatoid arthritis, or lupus, or to have received corticosteroids in the year prior to admission. Primary goal of the study was to determine whether early systemic corticosteroid treatment was associated with reduced mortality or need for mechanical ventilation. Overall, early use of systemic corticosteroids was not associated with in-hospital mortality or mechanical ventilation. However, there was a significant treatment effect based on C-reactive protein (CRP) levels. Early use of corticosteroids in patients with initial CRP levels of ≥20 mg/dL was associated with a significantly reduced risk of mortality or need for mechanical ventilation (odds ratio: 0.23). Conversely, such treatment in patients with initial CRP levels of &lt;10 mg/dL was associated with a significantly increased risk of mortality or need for mechanical ventilation (odds ratio: 2.64). The authors state that these findings suggest that appropriate selection of COVID-19 patients for systemic corticosteroid treatment is critical to maximize the likelihood of benefit and minimize the risk of harm. Note: The limitations of the observational study design should be considered when interpreting these results. Corticosteroid dosages used in patients included in this study not provided. Further study is needed to determine the role of CRP levels in guiding the use of corticosteroid treatment in patients with COVID-19.</td>

| Methylprednisolone studies for treatment of COVID-19 pneumonia or ARDS: Registered clinical trials that have been initiated or underway include: | | | NCT04359511  
NCT04360876  
NCT04395105 | | |
| Methylprednisolone non-randomized pilot study (NCT04355247): Trial has been initiated to evaluate use of the drug for the prevention of COVID-19 cytokine storm and progression to respiratory failure. | | | | |
| Corticosteroids (inhaled) | 68:04 | Inhaled corticosteroids may mitigate local inflammation and inhibit virus proliferation. | There are currently no published studies specifically evaluating use of inhaled corticosteroids in patients with COVID-19.  
A small case series from Japan observed possible clinical benefit in 3 patients with mild to moderate COVID-19 pneumonia following oral inhalation of ciclesonide; however, without a control group, it is not known whether the patients would have improved spontaneously.  
Clinical trials evaluating the use of inhaled corticosteroids (e.g., budesonide, ciclesonide) in patients with COVID-19 are being planned or underway, including the following trials registered at clinicaltrials.gov:  
NCT04330586  
NCT04355637  
NCT04377711  
NCT04381364  
NCT04416399  
NCT04435795 | Initial dosage of orally inhaled ciclesonide used in the published case series from Japan of 3 patients with COVID-19 pneumonia was 200 mcg 2 times daily. If necessary, the dosage was increased to 400 mcg 3 times daily. The authors suggested continued use of ciclesonide oral inhalation for about 14 days or longer.  
NIH COVID-19 Treatment Guidelines Panel recommends that inhaled corticosteroids used daily for the management of asthma and COPD to control airway inflammation should not be discontinued in patients with COVID-19. The panel also states that no studies to date have investigated the relationship between inhaled corticosteroids in these clinical settings and virus acquisition, severity of illness, or viral transmission.  
Currently, there is no clinical evidence supporting adverse or beneficial effects of premorbid use or continued administration of inhaled corticosteroids in patients with acute respiratory infections due to coronaviruses. Randomized controlled clinical studies are needed to assess the benefits of inhaled corticosteroids for treatment of COVID-19 in patients with and without chronic respiratory conditions. | | |

<tr>
<td>Inhaled prostacyclins (e.g., epoprostenol, iloprost)</td>
<td>48:48 Vasodilating Agents</td>
<td>Selective pulmonary vasodilators; may be useful in the adjunctive treatment of acute respiratory distress syndrome (ARDS), a complication of COVID-19.</td>
<td>There are currently no published studies specifically evaluating use of inhaled prostacyclins in COVID-19 patients.</td>
<td>Various dosages of inhaled epoprostenol have been used in patients with ARDS: Dosages up to 50 ng/kg per minute (titrated to response) have been used in clinical studies. To provide a clinically important increase in PaO₂ and reduction in pulmonary artery pressure, data from these studies suggest that the most effective and safe dosage appears to be 20-30 ng/kg per minute in adults and 30 ng/kg per minute in pediatric patients.</td>
<td>The Surviving Sepsis Campaign states that due to the lack of adequately powered randomized controlled studies, a recommendation cannot be made for or against the use of inhaled prostacyclins in COVID-19 patients with severe ARDS.</td>
</tr>
<tr>
<td>Interferons</td>
<td>8:18.20 Interferons</td>
<td>Interferons (IFNs) modulate immune responses to some viral infections; in vitro studies indicate only weak induction of IFN following SARS-CoV-2 infection, and a possible role for IFNs in prophylaxis or early treatment of COVID-19 has been suggested to compensate for possibly insufficient endogenous IFN production.</td>
<td>Only limited clinical trial data available to date specifically evaluating efficacy of IFNs for treatment of COVID-19. Information on additional studies including IFN alfa or IFN beta as a component of combination therapy (e.g., background regimen), see antiviral entries in this Evidence Table. Clinical trials are currently evaluating IFN beta-1a or IFN beta-1b, generally added to other antivirals, for treatment of COVID-19, including: NCT04492475 (IFN beta-1a) NCT04465695 (IFN beta-1b) NCT04494399 (IFN beta-1b) NCT04324463 (IFN beta) NCT04343768 (IFN beta-1a, IFN beta-1b) NCT04385095 (SNG001 [inhaled IFN beta-1a]) (manufacturer announced very preliminary “positive” findings for a hospitalized subset of patients in a press release, but rigorous reporting of complete findings still pending).</td>
<td>IFN beta: Various sub-Q dosages of IFN beta-1a and IFN beta-1b are being evaluated for treatment of COVID-19. Open-label, randomized study in hospitalized adults with COVID-19, mainly mild disease (NCT04276688): IFN beta-1b 8 million units was given sub-Q on alternate days for 1, 2, or 3 doses (when initiated on day 5-6, 3-4, or 1-2, respectively, following symptom onset) in conjunction with 14-day regimen of LPV/RTV and ribavirin. In an open-label, randomized study in hospitalized adults with severe COVID-19, IFN beta-1a 12 million units was given sub-Q 3 times weekly for 2 weeks. Efficacy and safety of IFNs for treatment or prevention of COVID-19 not established. Relative effectiveness of different IFNs against SARS-CoV-2 not established. NIH COVID-19 Treatment Guidelines Panel recommends against use of IFNs for treatment of severe or critical COVID-19, except in the context of a clinical trial. The panel also states there are insufficient data to recommend either for or against use of IFN beta for the treatment of early (i.e., &lt;7 days from symptom onset) mild or moderate COVID-19. No benefit was observed with use of IFNs for treatment of other severe or critical coronavirus infections (SARS, MERS), and toxicity of IFNs outweighs the potential for benefit. IFNs may have antiviral activity early in the course of SARS-CoV-2 infection;</td>

<td></td>
<td>Open-label, randomized study in Hong Kong in hospitalized adults with COVID-19, mainly mild disease (NCT04276688): Combination regimen of LPV/RTV, ribavirin, and sub-Q IFN beta-1b (IFN beta-1b was omitted to avoid proinflammatory effects when treatment was initiated 7-14 days after symptom onset) was associated with shorter median time from treatment initiation to negative RT-PCR result in nasopharyngeal swab (7 vs 12 days), earlier resolution of symptoms (4 vs 8 days), and shorter hospital stay (9 vs 14.5 days) compared with control (LPV/RTV). In the subset of patients initiating treatment 7 or more days after symptom onset (i.e., those not treated with IFN beta-1b), there was no significant difference in time to negative RT-PCR result, time to resolution of symptoms, or duration of hospital stay between the combination regimen (LPV/RTV and ribavirin) and control (LPV/RTV). IFN beta-1b (8 million units on alternate days) was administered for 1, 2, or 3 doses when initiated on day 5-6, 3-4, or 1-2, respectively, following symptom onset (median of 2 IFN beta-1b doses given); 52 of 86 patients (60%) randomized to combination regimen received all 3 drugs, and 41 patients received control LPV/RTV.</td>
<td>IFN beta: Chinese guidelines suggest IFN alfa dosage of 5 million units (or equivalent) twice daily via atomization inhalation for treatment of COVID-19. Peginterferon lambda-1a: For treatment of COVID-19 in adults (NCT04354259, NCT04388709): Peginterferon lambda-1a 180 mcg sub-Q; number of doses (1 dose or 2 doses given 1 week apart) depends on the protocol. Two 180-mcg sub-Q doses of peginterferon lambda-1a given 1 week apart.</td>
<td>however, there are insufficient data to assess the potential benefit of IFN use during early disease versus the risk of toxicity. Surviving Sepsis Campaign COVID-19 subcommittee states that there is insufficient evidence to issue a recommendation on use of interferons, alone or in combination with antivirals, in critically ill adults with COVID-19. Peginterferon lambda-1a via atomization inhalation is included in Chinese guidelines as a possible option for treatment of COVID-19.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>cell lines; IFN beta is more active than IFN alfa in vitro against SARS-CoV-1 and MERS-CoV 2, 8, 12. IFN alfa and IFN beta are active in vitro against SARS-CoV-2 in Vero cells at clinically relevant concentrations; in vitro study suggests SARS-CoV-2 is more sensitive than SARS-CoV-1 to IFN alfa 1, 3. However, lack of clinical benefit observed with use of type 1 IFNs, generally in combination with ribavirin, for treatment of SARS and MERS 1, 8, 9, 11, 12. IV IFN beta-1a did not reduce ventilator dependence or mortality in a placebo-controlled trial in patients with acute respiratory distress syndrome (ARDS) 11, 17.</td>
<td>Open-label, randomized study in Iran in hospitalized adults with severe suspected or RT-PCR-confirmed COVID-19: IFN beta-1a (12 million units sub-Q 3 times weekly for 2 weeks) plus standard care (7- to 10-day regimen of hydroxychloroquine plus lopinavir/ritonavir or atazanavir/ritonavir) (n = 42) was compared with standard care (control; n = 39). Time to clinical response (primary outcome; defined as hospital discharge or 2-score improvement in a 6-category ordinal scale) did not differ significantly between the IFN beta-1a group and the control group (9.7 vs 8.3 days); durations of hospital stay, ICU stay, and mechanical ventilation also did not differ between the groups. Discharge rate on day 14 (67% vs 44%) was higher and 28-day overall mortality rate (19 vs 44%) was significantly lower with IFN beta-1a compared with Peginterferon lambda-1a.</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Type 3 IFNs (IFN lambda) are thought to provide important immunologic defense against respiratory viral infections 1, 4, 5, 19 and may have less potential than type 1 IFNs to produce systemic inflammatory response, including inflammatory effects on respiratory tract; IFN lambda receptor is expressed mainly on epithelial (including respiratory epithelial) cells and neutrophils, and is distinct from the ubiquitous type 1 IFN receptor; despite different receptors and expression patterns, type 1 and type 3 IFNs activate</td>
<td>IFN alfa: Chinese guidelines suggest IFN alfa dosage of 5 million units (or equivalent) twice daily via atomization inhalation for treatment of COVID-19. Peginterferon lambda-1a: For treatment of COVID-19 in adults (NCT04354259, NCT04388709): Peginterferon lambda-1a 180 mcg sub-Q; number of doses (1 dose or 2 doses given 1 week apart) depends on the protocol. | Sarilumab (Kevzara®) | 92:36 Disease-modifying Anti-rheumatic Drug | Recombinant humanized monoclonal antibody specific for the interleukin-6 (IL-6) receptor; IL-6 is a proinflammatory cytokine. Sarilumab may potentially combat cytokine release syndrome (CRS) and pulmonary symptoms in severely ill patients. | Preliminary unpublished data from randomized clinical trials have not demonstrated efficacy in treatment of patients with COVID-19. However, based on encouraging results in China with a similar drug, tocilizumab, a large, U.S.-based, phase 2/3, randomized, double-blind, placebo-controlled, adaptively designed study (NCT04315298) evaluating efficacy and safety of sarilumab in patients hospitalized with severe COVID-19 was performed. Patients in this study were randomized (2:2:1) to receive sarilumab 400 mg, sarilumab 200 mg, or placebo. Randomization was stratified by severity of illness (e.g., severe, critical, multisystem organ dysfunction) and use of systemic corticosteroids. In the phase 2 part of the study, sarilumab at both dosages reduced C-reactive protein (CRP) levels. The primary efficacy outcome measure in phase 3 was the change on a 7-point scale; this phase was modified to focus on the 400-mg dose of sarilumab in the critically ill patient group. During the course of the trial, there were many amendments that increased the sample size and modified the dosing strategies, and multiple interim analyses were performed. The results did not demonstrate a clinical benefit of sarilumab for any of the disease severity subgroups or dosing strategies studied. A second manufacturer-sponsored phase 3 clinical trial was conducted in countries outside the U.S. (Argentina, Brazil, Canada, Chile, France, Germany, Israel, Italy, Japan, Spain) in 420 severely or critically ill patients hospitalized with COVID-19 did not meet its primary endpoint and key secondary endpoint when sarilumab was compared with placebo in addition to usual hospital care. Although not statistically significant, trends were observed toward a decrease in duration of hospital stay, an acceleration in time to improved clinical outcomes, reduced mortality in the critically ill patient group not seen in the severely ill group, and a shortened time to discharge. | Large US-based controlled study (NCT04315298): Dosage of 400 mg IV as a single dose or multiple doses (based on protocol criteria); the lower-dose (200-mg) treatment arm was discontinued following a preliminary analysis of study results (see Trials or Clinical Experience) Note: IV formulation not commercially available in the U.S., but was studied in the above-mentioned clinical trial. The sub-Q formulation is not FDA-labeled to treat cytokine release syndrome (CRS) in the U.S. | NIH COVID-19 Treatment Guidelines Panel recommends against use of sarilumab in the treatment of COVID-19, except in a clinical trial. No new safety findings observed with use in COVID-19 patients.

**Italian case series (Benucci et al.)** describes 8 patients hospitalized with COVID-19 pneumonia at one hospital in Florence treated with sarilumab (initial 400-mg IV dose followed by 200-mg IV doses after 48 and 96 hours) in addition to standard therapy (hydroxychloroquine, azithromycin, darunavir, cobicistat, enoxaparin). Treatment was started within 24 hours of hospitalization. Sarilumab was used in these patients because of a lack of tocilizumab at this institution. Seven of the patients demonstrated an improvement in oxygenation and lung echo score and were discharged within 14 days; the remaining patient died in 13 days.

**Multiple clinical trials to evaluate sarilumab for treatment of COVID-19** are registered at clinicaltrials.gov.

For compassionate use access or investigator-sponsored clinical studies, contact the manufacturer (Sanofi Genzyme) for further information (1-800-633-1610).

Antineoplastic agents

Recombinant chimeric monoclonal antibody specific for the interleukin-6 (IL-6) receptor; may potentially combat cytokine release syndrome (CRS) symptoms (e.g., fever, organ failure, death) in severely ill patients

**Italy:** Non-peer-reviewed findings from an observational cohort study of 30 patients with COVID-19 and pneumonia/acute respiratory distress syndrome (ARDS) who participated in a compassionate use program in one hospital in Italy (SISCO study; NCT04322188) and were followed for at least 30 days showed reduced C-reactive protein (CRP) levels by day 14. The siltuximab-treated patients were compared with 30 propensity score-matched patients receiving best supportive care. The 30-day mortality rate was substantially lower in the siltuximab group compared with the matched-control cohort. Out of the 30 patients treated with siltuximab, 16 (53%) were discharged from the hospital, 4 (13%) remained hospitalized on mechanical ventilation, and 10 patients died.

Other clinical trials evaluating siltuximab in the treatment of COVID-19 currently are recruiting in Belgium (NCT04330638), Spain (NCT04329650), and Saudi Arabia (NCT04486521).

In the SISCO study in Italy, patients received an initial dose of siltuximab 11 mg/kg by IV infusion over 1 hour; a second dose could be administered at the physician’s discretion.

Other clinical studies under way are evaluating a single siltuximab dose of 11 mg/kg by IV infusion.

Efficacy and safety of siltuximab in the treatment of COVID-19 not established.

<td><strong>Sirolimus</strong> (Rapamune®)<strong>Updated 8/6/20</strong></td>
<td>92:44 Immunosuppressive agent; mammalian target of rapamycin (mTOR) inhibitor</td>
<td>mTOR complex 1 (mTORC1) is involved in the replication of various viruses, including coronavirus 1, 2, 5 In vitro studies demonstrated inhibitory activity against MERS-CoV infection 2 Limited experience in patients with H1N1 pneumonia suggests possible benefit; in one study, treatment with sirolimus 2 mg daily in conjunction with corticosteroids for 14 days was associated with improved patient outcomes (e.g., shortened duration of mechanical ventilation, improved hypoxia and multiorgan function) 3 T cell dysregulation has been observed in patients with severe COVID-19 and is thought to be a possible cause of cytokine storm; when given early prior to the cytokine storm phase, sirolimus may prevent progression to severe COVID-19 by restoring T-cell functionality 7 Clinical trials evaluating sirolimus for the treatment of COVID-19 are planned or underway including the following trials: 4 NCT04341675 (SCOPE) NCT04374903 (COVID19-HOPE) NCT04371640 NCT04461340 NCT04482712 (RAPA-CARDS) Various dosing regimens are being evaluated in registered trials 4</td>
<td></td>
<td>Although possible clinical application, current data not specific to COVID-19; additional study needed 5</td>
<td></td>
</tr>
<tr>
<td><strong>Tocilizumab</strong> (Actemra®)<strong>Updated 9/10/20</strong></td>
<td>92:36 Disease-modifying Anti-rheumatic Drug</td>
<td>Recombinant humanized monoclonal antibody specific for the interleukin-6 (IL-6) receptor; IL-6 is a proinflammatory cytokine. Tocilizumab may potentially combat cytokine release syndrome (CRS) and pulmonary symptoms in severely ill COVID-19 patients 1, 3, 6, 9, 10, 14 Preliminary unpublished data from randomized clinical trials have not demonstrated efficacy in treatment of patients with COVID-19 9 Case reports and observational and open studies describing use of tocilizumab in patients with COVID-19 reported from various areas of the world 1, 3, 5, 10, 12, 15, 17 In preliminary data from a non-peer-reviewed, single-arm, observational Chinese trial (Xu et al.) involving 21 patients with severe or critical COVID-19 infection, patients demonstrated rapid fever reduction and a reduced need for supplemental IV infusion: China recommends an initial dose of 4–8 mg/kg infused over more than 60 minutes. If initial dose not effective, may administer second dose (in same dosage as initial dose) after 12 hours. No more than 2 doses should be given; Tocilizumab is typically given IV to treat cytokine release syndrome (CRS) and in patients with COVID-19; however, the drug has been given subcutaneously in some patients 9, 17 The subcutaneous formulation of tocilizumab is not intended for IV use 9</td>
<td>Various dosing regimens are being evaluated in registered trials 4</td>
<td>In China, tocilizumab can be used to treat severely or critically ill COVID-19 patients with extensive lung lesions and high IL-6 levels 2 NIH COVID-19 Treatment Guidelines Panel recommends against use of tocilizumab in the treatment of COVID-19, except in a clinical trial 9 The role of routine cytokine measurements (e.g., IL-6, CRP) in determining the severity of and treating COVID-19 requires further study 14</td>

<tr>
<td>Vitamin D</td>
<td>88:16</td>
<td>Vitamin D receptor is expressed on immune cells (e.g., B cells, T cells, antigen-presenting cells); these cells can synthesize and respond to active vitamin D. Vitamin D modulates innate and adaptive immune responses; may downregulate proinflammatory cytokines and upregulate anti-inflammatory cytokines, increase T regulatory cell activity, and reduce cytokine storm induced by innate immune system. Vitamin D deficiency is associated with increased autoimmunity and increased susceptibility to infection. In observational studies, low vitamin D concentrations have been associated with increased risk of community-acquired pneumonia in older adults and upper respiratory viral infections in children. Vitamin D deficiency is common in the U.S., particularly in Hispanic and Black populations (groups overrepresented among U.S. COVID-19 cases). Vitamin D deficiency also is more common in older patients and patients with obesity and hypertension (factors potentially associated with worse COVID-19 outcomes). Association also suggested between vitamin D and various doses of vitamin D are being evaluated for prevention or treatment of COVID-19. High concentrations of vitamin D may cause hypercalcemia and nephrocalcinosis; currently no convincing scientific evidence that very high intake of vitamin D will be beneficial in preventing or treating COVID-19. National Academy of Sciences (NAS) guidelines for adequate dietary intake of vitamin D for bone health in US population: Estimated Average Requirement (EAR) in children and adults 1-70 years of age is 400 units (10 mcg) daily; Recommended Dietary Allowance (RDA) in these age groups is 600 units (15 mcg) daily. In adults &gt;70 years of age, EAR is 400 units (10 mcg) daily and RDA is 800 units (20 mcg). These reference values assume minimal sun exposure. NAS states that data indicate that a serum 25-hydroxyvitamin D concentration of 50 nmol/L is sufficient to meet the needs of 97.5% of the population and concentrations &lt;30 nmol/L are associated with clinical deficiency. Efficacy of vitamin D supplementation in the prevention or treatment of COVID-19 has not been established. Some experts recommend maintaining recommended levels of vitamin D intake during the COVID-19 pandemic to maintain bone and muscle health and avoid deficiency. NIH COVID-19 Treatment Guidelines Panel states that there is insufficient data to recommend either for or against use of vitamin D for prevention or treatment of COVID-19. Joint guidance from the American Society for Bone and Mineral Research (ASBMR), American Association of Clinical Endocrinologists (AACE), Endocrine Society, European Calcified Tissue Society (ECTS), National Osteoporosis Foundation (NOF), and International Osteoporosis Foundation (IOF) emphasizes importance of obtaining the recommended daily dosage of vitamin D; for those unable to obtain recommended durations of direct sun exposure during the pandemic, recommended intake of vitamin D can be obtained through supplemental vitamin D. The joint guidance states that current data do not provide any evidence that vitamin D supplementation will help prevent or treat COVID-19. Advisory statement from the UK National Institute for Health and Care Excellence (NICE) states that there is no evidence to support taking vitamin D supplements to specifically prevent or treat COVID-19. However, all individuals should continue to follow current recommendations on daily vitamin D supplementation to maintain bone and muscle health during the pandemic.</td>

<tr>
<td>Zinc</td>
<td></td>
<td>Trace mineral involved in immune function, including antibody and white blood cell production; an important cofactor for many enzymes; 1,3 may improve wound healing&lt;sup&gt;9&lt;/sup&gt;</td>
<td>Zinc deficiency increases proinflammatory cytokine concentrations (interleukin-1 [IL-1], IL-6, TNF alpha) and decreases antibody production; zinc supplementation increases the ability of polymorphonuclear cells to fight infection&lt;sup&gt;1&lt;/sup&gt;. Possible antiviral activity; zinc appears to inhibit virus RNA polymerase activity and viral replication in an in vitro and cell culture model of severe acute respiratory syndrome coronavirus 1 (SARS-CoV-1). 1,7 High-dose zinc supplementation reduced the duration but not severity of diabetes mellitus (a condition also associated with worse COVID-19 outcomes). 20, 22, 27 Clinical trials are evaluating the relationship between vitamin D concentration and COVID-19 disease severity and mortality (e.g., NCT04394390, NCT0403932, NCT04487951); some preliminary retrospective observational data suggest an association between vitamin D concentration and COVID-19 risk or severity/mortality, but may not account for potential confounding factors. 17, 19</td>
<td>No evidence from controlled trials that zinc is effective in the prevention or treatment of COVID-19&lt;sup&gt;5, 6&lt;/sup&gt; Because of its role in immune function and potential to decrease coronavirus replication, zinc is being evaluated in a number of clinical trials in both the prophylaxis and treatment of COVID-19, sometimes in combination with other supplements (including vitamin C, vitamin D, and selenium) and drugs (including hydroxychloroquine)&lt;sup&gt;1, 2, 5, 6&lt;/sup&gt; Retrospective observational study in New York City (Carlucci et al; non-peer-reviewed): Data were collected from electronic medical records to compare outcomes between hospitalized patients with COVID-19 who received hydroxychloroquine, azithromycin, and zinc (411 patients) and those who received hydroxychloroquine and azithromycin alone (521 patients). Zinc was given as a zinc sulfate 220-mg capsule (50 mg of elemental zinc) twice daily for 5 days. The addition of zinc did not affect the length of hospitalization, duration of ventilation, or duration of ICU stay, but patients in the treatment group that included zinc were discharged home more frequently and the need for ventilation, ICU (possibly dose dependent), vomiting, and changes in taste 1, 6, 7, 8 Some clinicians have recommended an elemental zinc intake of 30-50 mg/day in the short-term treatment of influenza and coronavirus infections&lt;sup&gt;1, 4&lt;/sup&gt; Appropriate dosage regimens not established in either the prophylaxis or treatment of COVID-19; various supplementation regimens being evaluated in clinical trials, with a maximum dosage of zinc sulfate of 220 mg (50 mg of elemental zinc) twice daily 2, 3, 6, 9, 10 Oral zinc supplementation likely safe in dosages up to 40 mg of elemental zinc daily in adults; safety of dosages exceeding those used in the management of the common cold not known 3, 6, 8 Zinc Recommended Dietary Allowance (RDA): Adult males: 11 mg/day; adult females: 8 mg/day&lt;sup&gt;3, 8&lt;/sup&gt; Despite some anecdotal claims in the media that zinc is effective in treating COVID-19, unclear whether zinc supplementation is beneficial in the prophylaxis and/or treatment of COVID-19; further study is needed 1, 3, 8 NIH COVID-19 Treatment Guidelines Panel states that there are insufficient clinical data to recommend either for or against use of zinc in the treatment of COVID-19&lt;sup&gt;9&lt;/sup&gt; NIH COVID-19 Treatment Guidelines Panel recommends against using zinc supplementation above the RDA for the prevention of COVID-19, except in a clinical trial&lt;sup&gt;9&lt;/sup&gt; Zinc concentrations are difficult to measure accurately since it is distributed as a component of various proteins and amino acids&lt;sup&gt;9&lt;/sup&gt; Adverse effects may include nausea (possibly dose dependent), vomiting, and changes in taste 1, 6, 7, 8 Long-term zinc supplementation may cause copper deficiency with adverse effects.</td>

| ACE Inhibitors, Angiotensin II Receptor Blockers (ARBs) | 24:32 Renin-Angiotensin-Aldosterone System Inhibitor | **Hypothetical harm:** Human pathogenic coronaviruses bind to their target cells through angiotensin-converting enzyme 2 (ACE2). Expression of ACE2 may be increased in patients treated with ACE inhibitors or ARBs. Increased expression of ACE2 may potentially facilitate COVID-19 infections.  
**Hypothetical benefit:** ACE inhibitors or ARBs may have a protective effect against lung damage or may have paradoxical effect in terms of virus binding.  
Large, observational study analyzed a cohort of pts tested for COVID-19 to evaluate the relationship between previous treatment with 5 common classes of antihypertensive agents (including ACE inhibitors, ARBs) and the likelihood of a positive or negative test result for COVID-19 as well as the likelihood of severe COVID-19 illness among pts who tested positive: Study included data obtained from a large health network in New York City for 12,594 pts who were tested for COVID-19 from Mar 1 to Apr 15, 2020. Among these pts, 4357 (34.6%) had a history of hypertension. Of these patients, 2573 (59.1%) tested positive for COVID-19. Among the 2573 pts with hypertension and positive results for COVID-19, 634 pts (24.6%) had severe disease (i.e., indicated by ICU admission, mechanical ventilation, or death). Results of COVID-19 testing were stratified in propensity-score-matched patients with hypertension according to previous treatment with selected antihypertensive agents. Propensity-score matching was based on age, sex, race, BMI, medical history, various comorbidities, and other classes of medications. The authors stated that no substantial increase was observed in the likelihood of a positive test for COVID-19 or in the risk of severe COVID-19 among patients who tested positive in association with any single antihypertensive class (including ACE inhibitors, ARBs).  
Large, population-based case-control study was conducted to evaluate the association between the use of RAAS blockers (including ACE inhibitors, ARBs) and the risk of COVID-19: Study included data obtained from a regional healthcare database in the Lombardy region of Italy for 6272 case pts with confirmed severe COVID-19: Patients with cardiovascular disease are at an increased risk of serious COVID-19 infections. Abrupt withdrawal of RAAS inhibitors in high-risk patients (e.g., heart failure patients, patients with prior myocardial infarction) may lead to clinical instability and adverse health outcomes. | Data are lacking; no evidence of harm or benefit with regards to COVID-19 infection.  
Large, observational study analyzed a cohort of pts tested for COVID-19 to evaluate the relationship between previous treatment with 5 common classes of antihypertensive agents (including ACE inhibitors, ARBs) and the likelihood of a positive or negative test result for COVID-19 as well as the likelihood of severe COVID-19 illness among pts who tested positive: Study included data obtained from a large health network in New York City for 12,594 pts who were tested for COVID-19 from Mar 1 to Apr 15, 2020. Abrupt withdrawal of RAAS inhibitors in high-risk patients (e.g., heart failure patients, patients with prior myocardial infarction) may lead to clinical instability and adverse health outcomes. | |  

American Heart Association (AHA), American College of Cardiology (ACC), Heart Failure Society of America (HFSA), European Society of Cardiology (ESC) recommend to continue treatment with renin-angiotensin-aldosterone system (RAAS) antagonists in those patients who are currently prescribed such agents. NIH COVID-19 Treatment Guidelines Panel states patients who are receiving an ACE inhibitor or ARB for cardiovascular disease (or other indications) should continue receiving these drugs; recommends against use of ACE inhibitors or ARBs for the treatment of COVID-19 except in the context of a clinical trial.  
Patients with cardiovascular disease are at an increased risk of serious COVID-19 infections. Abrupt withdrawal of RAAS inhibitors in high-risk patients (e.g., heart failure patients, patients with prior myocardial infarction) may lead to clinical instability and adverse health outcomes.

<td>Anticoagulants</td>
<td>20:12.04 Anti-coagulants</td>
<td>Patients with COVID-19, particularly those with severe disease, may develop a hypercoagulable state, which has been associated with poor outcomes (e.g., progressive respiratory failure, acute respiratory distress syndrome (ARDS), death).</td>
<td>Limited data from a retrospective study in China showed reduced mortality in COVID-19 patients with severe sepsis-induced coagulopathy or markedly elevated D-dimer levels (&gt;6 x ULN) who received prophylactic anticoagulation (low molecular weight heparin [LMWH] or unfractionated heparin [UFH]). Observational data derived from a single health system in the US suggested possible association between therapeutic-dose anticoagulation and decreased mortality. Among 786 patients who received systemic anticoagulation during their hospital course, mortality rate was 22.5% and median survival was 21 days compared with mortality rate of 22.8% and median survival of 14 days in those who did not receive systemic anticoagulation. In patients who required mechanical ventilation, mortality rate was 29.1% and median survival was 21 days for those receiving anticoagulation compared with a 62.7% mortality rate and a median survival of 9 days for those who did not receive anticoagulation. However, the study had important limitations (e.g., indications for anticoagulation initiation and details on patient characteristics not reported). Additional study is needed to understand the anticoagulant needs of COVID-19 patients. WHO recommends pharmacologic prophylaxis (e.g., LMWH) according to local and international standards for prevention of VTE in adults and adolescents hospitalized with COVID-19 unless contraindicated. The International Society for Thrombosis and Haemostasis and American Society of Hematology recommend prophylactic LMWH or UFH unless contraindicated.</td>
<td>See Comments column for available dosage-related information.</td>

| **COVID-19 Convalescent Plasma**  
Updated 9/17/20 |            | Plasma obtained from patients who have recovered from COVID-19 (i.e., COVID-19 convalescent plasma) that contains antibodies against SARS-CoV-2 may provide short-term passive immunity to the virus; theoretically, such immunity may prevent or contribute to recovery from the infection, possibly as the result of viral neutralization and/or other mechanisms. 1, 5, 24, 25 | Study with retrospectively matched control in US (Liu et al): Preliminary (non-peer-reviewed) data from a study of 39 hospitalized adults with severe to life-threatening COVID-19 who received ABO-compatible COVID-19 convalescent plasma (2 units [total volume approximately 500 mL] infused IV over 1-2 hours), obtained from donors with a SARS-CoV-2 anti-spike antibody titer of 1:320 or greater, suggest that stable or improved supplemental oxygen requirements by post-transfusion day 14 were more likely in these convalescent plasma recipients than in the matched control group not treated with convalescent plasma (odds ratio: 0.86); this effect appeared to be confounded by use of therapeutic anticoagulants, but not by other types of drugs (i.e., azithromycin, broad-spectrum antibiotics, hydroxychloroquine, corticosteroids, antivirals, interleukin-1 [IL-1] and IL-6 inhibitors) or duration of symptoms before admission. Overall, survival was improved in patients in the convalescent plasma group compared to the control group; after adjusting for covariates, data suggest a significant improvement in survival in non-intubated patients (hazard ratio: 0.19) receiving convalescent plasma, but not in the small cohort of intubated patients (hazard ratio: 1.24). No significant transfusion-related morbidity or mortality. | Emergency use authorization (EUA) COVID-19 convalescent plasma dosage and administration for hospitalized patients: Consider initiating therapy with one unit (approximately 200 mL) of COVID-19 convalescent plasma given IV through a peripheral or central venous catheter according to standard institutional transfusion guidelines. Additional COVID-19 convalescent plasma units may be administered based on the prescribing physician’s medical judgment and the patient’s clinical response. 27, 28  
Small volumes or prolonged transfusion times may be necessary in patients with impaired cardiac function and heart failure. 28  
Emergency use authorization (EUA) for COVID-19 convalescent plasma: FDA issued an EUA on August 23, 2020 that permits use of the biological product for the treatment of hospitalized patients with COVID-19. This EUA is based on historical evidence using convalescent plasma in prior outbreaks of respiratory viruses, certain preclinical evidence, results from small clinical trials of convalescent plasma conducted during the current outbreak, and data obtained from the ongoing National Expanded Access Treatment Protocol (EAP) for COVID-19 convalescent plasma sponsored by the Mayo Clinic. 27  
The EUA requires healthcare providers to provide convalescent plasma recipients with the Fact Sheet for Patients and Parents/Caregivers and to inform recipients of the significant known and potential risks and benefits of emergency use of COVID-19 convalescent plasma. | Efficacy and safety of COVID-19 convalescent plasma for the treatment of COVID-19 not established. 11, 25  
There are no convalescent blood products currently licensed by the FDA. COVID-19 convalescent plasma is regulated as an investigational product. 11, 37 |

<td></td>
<td></td>
<td><strong>Uncontrolled pilot study in China (Duan et al):</strong> 10 adults with severe COVID-19 received a single transfusion of COVID-19 convalescent plasma (containing SARS-CoV-2 neutralizing antibody titers of 1:640 or greater) with standard care; all patients received antiviral therapy (e.g., umifenovir [Arbidol®], ribavirin, oseltamivir, peramivir, interferon α) and 6 patients also received methylprednisolone. The median time from onset of symptoms to transfusion of convalescent plasma was 16.5 days. COVID-19 symptoms (fever, cough, shortness of breath, chest pain) improved in all patients within 1-3 days after the transfusion and all patients showed radiologic improvement in pulmonary lesions. Titers of neutralizing antibody increased in 5 patients after the transfusion, but remained the same in 4 patients. Prior to the transfusion, RT-PCR tests for SARS-CoV-2 RNA were positive in 7 patients and negative in 3 patients; after transfusion, SARS-CoV-2 RNA was undetectable in 3 patients on day 2, 3 patients on day 3, and 1 patient on day 6.</td>

<td>from symptom onset to plasma transfusion was 10 days and 24/25 patients received a single transfusion. Convalescent plasma was well tolerated and no transfusion-related adverse events were reported. At day 7 post-transfusion, 9 patients (36%) had clinical improvement (defined as at least a 1-point improvement based on a 6-point ordinal scale); by day 14 post-transfusion, 19 patients (76%) had clinical improvement or were discharged. The contribution of convalescent plasma to clinical improvement in these patients is unclear since there was no control group and patients also received other treatments.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Cochrane systematic review: Analysis of 20 published studies (1 RCT, 3 controlled non-randomized studies of interventions [NRSIs], 16 non-controlled NRSIs) evaluating convalescent plasma in adults with COVID-19 (total of 5443 study participants, of whom 5211 received COVID-19 convalescent plasma) found very low confidence in the efficacy and safety of this treatment approach. There was a high risk of bias within and across the studies and great variability in terms of study design, donor and recipient characteristics, and other previous or concurrent treatments.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Systematic review (Joyner et al; non-peer-reviewed): Analysis of pooled data (total of 804 COVID-19 patient outcomes) from 12 studies (3 RCT, 5 matched-control, 4 case series) evaluating convalescent plasma in hospitalized adults with severe or life-threatening COVID-19 found evidence favoring efficacy of this therapeutic approach. The risk of death was substantially reduced in hospitalized COVID-19 patients transfused with convalescent plasma compared to matched patients receiving standard therapy (OR: 0.43, p &lt;0.001). Note: There were several limitations to this analysis including aggregating mortality data across study populations that varied by dose and timing of convalescent plasma administration, geographic region, and duration of follow-up.</td>

<td>Additional pathways (outside of the EUA) for administering or studying the use of investigational COVID-19 convalescent plasma:</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>1). Clinical Trials: Requests to study use of COVID-19 convalescent plasma should be submitted to FDA under the traditional investigational new drug (IND) regulatory pathway.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>2). Expanded Access IND: FDA is accepting requests for expanded access INDs for use of COVID-19 convalescent plasma in patients with serious or immediately life-threatening COVID-19 who are not eligible or are unable to participate in randomized clinical trials. Consult the FDA guidance document for specific information on applying for an expanded access IND for more than a single patient.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>3). Single Patient Emergency IND (eIND): Licensed physicians seeking to administer COVID-19 convalescent plasma to individual patients with serious or life-threatening disease may request an eIND from the FDA. Consult the FDA guidance document for specific information on applying for an eIND.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Donor eligibility: FDA guidance suggests that COVID-19 convalescent plasma be collected from individuals with laboratory-confirmed evidence of COVID-19 infection and complete resolution of symptoms for at least 14 days before donation (a negative result for COVID-19 by a diagnostic test is not necessary to qualify the donor).</td>

<tr>
<td></td>
<td></td>
<td></td>
<td>Open-label, randomized, controlled study in Netherlands (Gharbharan et al; Con-COVID study): Preliminary (non-peer-reviewed) data from a study of 86 hospitalized adults with COVID-19 found no significant difference in mortality, duration of hospital stay, or disease severity on day 15 in patients treated with convalescent plasma (300 mL of convalescent plasma containing anti-SARS-CoV-2 neutralizing antibody titers of ≥1:80) compared with standard of care. <strong>Note:</strong> Anti-SARS-CoV-2 antibodies were detected at baseline in 53/66 patients who had been symptomatic for 10 days prior to study enrollment. Neutralizing antibodies were detected in 44/56 (79%) patients tested with median titers comparable to the donors (1:160). These findings raised concerns about the potential benefit of convalescent plasma in the study population and the study was terminated. 44</td>
<td>Antibody titers in donor plasma: According to the EUA, COVID-19 convalescent plasma with an S/Co value of ≥12 (as determined by the Ortho VITROS SARS-CoV-2 IgG test) qualifies as high-titer COVID-19 convalescent plasma. 37 Low-titer COVID-19 convalescent plasma must be labeled accordingly and may be considered for use following assessment of the potential benefits and risks of convalescent plasma therapy for the individual patient. 37, 38</td>
<td></td>
</tr>
</tbody>
</table>
or critically ill hospitalized adults with COVID-19 who received convalescent plasma (up to 2 transfusions of 200 mL of convalescent plasma containing IgG titers of 1:320) found a significant reduction in mortality (13 versus 55%, respectively) and hospital length of stay (15.4 versus 33 days, respectively) in those who were severely ill compared with those who were critically ill.

**Note:** Severely ill patients received convalescent plasma approximately 4.6 days following hospital admission and 12.6 days following symptom onset while on high-flow oxygen supplementation without evidence of acute respiratory distress syndrome (ARDS). Critically ill patients received convalescent plasma approximately 16.4 days following hospital admission and 23.1 days following symptom onset after developing ARDS; these patients also had been on ventilation support for an average of 10.6 days prior to transfusion of convalescent plasma. Transient transfusion reaction (fever and hematuria) was observed within 2 hours of transfusion of convalescent plasma in one patient with severe illness.  

**Expanded access IND protocol (Joyner et al):** Analysis of 35,322 adults hospitalized with laboratory-confirmed SARS-CoV-2 infection who had or were considered at high risk of progression to severe or life-threatening COVID-19 who participated in a US FDA Expanded Access Program (NCT04338360) suggests that 7- and 30-day mortality rates are substantially reduced in patients transfused with convalescent plasma within 3 days of COVID-19 diagnosis. Patients received at least one unit (approximately 200 mL) of ABO-compatible COVID-19 convalescent plasma IV according to institutional transfusion guidelines. A statistically significant difference in crude 7-day mortality was observed between patients transfused with convalescent plasma within 3 days of COVID-19 diagnosis compared with those transfused with convalescent plasma 4 or more days after COVID-19 diagnosis (8.7 vs 11.9%). Similar findings were observed for 30-day mortality rate (21.6 vs 26.7%). A reduction in 7- and

<td>30-day mortality rate also was observed in patients transfused with convalescent plasma containing higher IgG antibody levels (&gt;18.45 signal-to-cut-off [S/Co] ratio) compared with those transfused with convalescent plasma containing IgG antibody levels ≤18.45 S/Co. Analysis of key safety indicators in 20,000 adults who participated in this Expanded Access Program suggests that IV transfusion of convalescent plasma is safe in hospitalized patients with COVID-19. Within the first 4 hours after transfusion, 146 serious adverse events (i.e., transfusion-associated circulatory overload, transfusion-related acute lung injury [TRALI], severe allergic transfusion reaction) were reported (incidence of &lt;1% of all transfusions with a mortality rate of 0.3%); however, only 13/146 serious adverse events were judged by the treating clinician as related to convalescent plasma transfusion. Within 7 days after transfusion, 1136 other serious adverse events were reported (i.e., thromboembolic or thrombotic event, sustained hypotensive event requiring IV vasopressor, cardiac event); however, 55/87 thromboembolic or thrombotic complications and 569/643 cardiac events were judged to be unrelated to convalescent plasma transfusion. Open-label, prospective study (Madariaga et al; non-peer-reviewed): The relationship between clinical and serologic parameters in a group of COVID-19 convalescent plasma donors and antibody responses in recipients of convalescent plasma was evaluated. SARS-CoV-2 anti-receptor binding domain (anti-RBD) and anti-spike antibody titers ranged from 0 to 1:3892 and 0 to 1:3289, respectively, in 103 convalescent plasma donors; mean duration of COVID-19 symptoms in the plasma donors was 11.9 days and mean interval between symptom onset and convalescent plasma donation was 45.1 days; predictors of higher antibody titers in the donors included advanced age, fever, absence of myalgia, fatigue, ABO blood type, and previous hospitalization. In this study, 10 hospitalized adults with severe or life-threatening COVID-19 received 1 or 2 units</td>

<tr>
<td></td>
<td></td>
<td></td>
<td>Retrospective matched cohort study of COVID-19 patients hospitalized, but not requiring intubation within the first 48 hrs, at a single New York medical center indicated that the risk for the composite outcome of death or intubation was reduced (mainly due to difference in mortality) in patients who received famotidine within 24 hours of hospital admission (n = 84) vs those who did not receive the drug (n = 1536); overall, 21% of patients met the composite outcome (8.8% were intubated and 15% died); the finding appeared to be specific to the H2 antagonist and to COVID-19, as the investigators reported observing no protective effect with proton-pump inhibitors or in non-COVID-19 patients. Home use of famotidine was documented on admission in 15% of patients who received the drug in hospital vs 1% of those who did not; 28% of all famotidine doses were IV; 47% of doses were 20 mg, 35%</td>

|         |            |           | **Trials or Clinical Experience** in hospitalized patients with RT-PCR-confirmed COVID-19: In-hospital mortality (14.5 vs 26%) and the combined end point of death or intubation (7.2 vs 13.8%) were reduced in patients who received famotidine (n = 83) compared with a propensity score-matched group of patients who did not receive the drug (n = 689). Famotidine use was identified from electronic medical records and was defined as IV or oral use at any dosage within 7 days before or after COVID-19 screening and/or hospitalization; in the famotidine group, 66% received the drug in hospital only, and 29% received the drug both before and during hospitalization. Median total in-hospital dose was 80 mg (range: 40-160 mg) given over a median of 4 days (range: 2-8 days). There were no significant differences between the groups with respect to baseline demographics, comorbidities, or severity of illness or in concomitant use of hydroxychloroquine, remdesivir, azithromycin, or corticosteroids.**  
**Uncontrolled series of hospitalized patients with COVID-19 receiving open-label, combined H₂ and H₁ antagonist therapy (famotidine and cetirizine) for ≥48 hours (not peer reviewed): Total of 110 patients at a single hospital received famotidine 20 mg and cetirizine hydrochloride 10 mg orally or IV every 12 hours; concomitant therapy included hydroxychloroquine (85%), tocilizumab (51%), methylprednisolone (31%), and convalescent plasma (30%). Findings included a 16.4% overall rate of intubation, 7.3% rate of intubation after ≥48 hours of treatment, 15.5% mortality rate, and 11-day average hospital stay. Note: Comparisons were limited to published outcome data from other locales for patients receiving “standard-of-care” regimens.** | | |

<td>HMG-CoA Reductase Inhibitors (statins)</td>
<td>24:06 Antilipemic Agents</td>
<td>In addition to lipid-lowering effects, statins have anti-inflammatory and immunomodulatory effects, which may prevent acute lung injury.</td>
<td>Data from randomized controlled trials are lacking on the use of statins in patients with COVID-19.</td>
<td></td>
<td>NIH COVID-19 Treatment Guidelines Panel states patients who are receiving a statin for the treatment or prevention of cardiovascular disease should continue statin therapy; recommends against use of statins for the treatment of COVID-19 except in the context of a clinical trial. Patients with cardiovascular disease are at an increased risk of serious COVID-19 infections. In patients with active COVID-19 who may develop severe rhabdomyolysis, it may be advisable to withhold statin therapy for a short period of time. Most statins are substrates for the CYP450 system; potential for drug interactions. Clinicians should ensure that their high-risk primary prevention (for ASCVD) patients are on guideline-directed statin therapy.</td>
</tr>
<tr>
<td>Updated 8/20/20</td>
<td></td>
<td>Statins affect ACE2 as part of their function in reducing endothelial dysfunction.</td>
<td>Retrospective cohort study in 13,981 patients in China hospitalized with COVID-19: Statin use during hospitalization was associated with lower risk of mortality. The 28-day all-cause mortality was 22% lower in patients who received statins during hospitalization compared with patients who did not receive statins. Among propensity-score-matched patients (861 patients in the statin group vs. 3444 matched patients in the no-statin group), the risk of 28-day all-cause mortality was 42% lower in patients who received statins during hospitalization compared with those who did not receive statins. In addition, lower incidence of invasive mechanical ventilation was observed in the statin-treated patients. The authors note that patients in the statin group were older and had a higher prevalence of comorbidities and more severe symptoms at baseline; matched non-statin patients therefore had more severe baseline symptoms and comorbidities than unmatched patients, which could account for the increased mortality in the non-statin group after propensity score matching.</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>Retrospective cohort study in 154 nursing home residents in Belgium with clinically suspected COVID-19 and/or positive PCR test for SARS-CoV-2: Statin use was associated with absence of symptoms (i.e., asymptomatic infection) in this cohort; 45% of the 31 patients receiving statin therapy remained asymptomatic compared with 22% of the 123 patients not receiving statins. Preliminary findings have shown mixed results with other respiratory illnesses; some observational studies suggest statin therapy is associated with a reduction in various cardiovascular outcomes and possibly mortality in patients hospitalized with influenza and/or pneumonia.</td>

<td></td>
<td>In vitro evidence of activity against SARS-CoV-2 in infected Vero-hSLAM cells reported with high concentrations of the drug.</td>
<td>Pilot observational study comparing efficacy of add-on ivermectin in pts with mild to moderate COVID-19 (not peer reviewed): A total of 16 pts received a single dose of oral ivermectin (0.2 mg/kg) given on the day of hospital admission in addition to initiation of treatment with hydroxychloroquine and azithromycin, and results were compared with 71 pts who received hydroxychloroquine and azithromycin alone (matched controls). The primary outcome was percentage of pts cured (defined as symptoms free to be discharged from the hospital and 2 consecutive negative PCR tests from nasopharyngeal swabs at least 24 hours apart) within 23 days. The investigators reported that all 16 pts who received ivermectin were cured compared with 97% of pts who did not receive ivermectin and the mean duration of hospitalization was shorter in the ivermectin group (7.6 days) than in the control group (13.2 days). Note: These results need to be validated in a larger prospective trial.</td>
<td>ivermectin for the treatment of COVID-19, except in a clinical trial.</td>
<td>Ivermectin plasma concentrations attained with dosages recommended for treatment of parasitic infections are substantially lower than concentrations associated with in vitro inhibition of SARS-CoV-2; pharmacokinetic modeling predicts that plasma concentrations attained with dosages up to 10 times higher than usual dosage also are substantially lower than concentrations associated with in vitro inhibition of the virus. FDA issued a warning concerning possible inappropriate use of ivermectin products intended for animals as an attempt to self-medicate for the treatment of COVID-19.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Retrospective observational evaluation of COVID-19 pts treated with ivermectin (not peer reviewed): Outcome data for 173 pts with confirmed COVID-19 who received at least one dose of oral ivermectin (0.2 mg/kg) at any time during hospitalization, at the discretion of the treating physician, in addition to usual care were compared with outcome data for 107 pts who received usual care. The primary outcome measure was all-cause in-hospital mortality. The investigators reported that overall mortality was lower in the ivermectin group (15%) than in the group not treated with ivermectin (25.2%); there was no difference in duration of hospitalization between the groups (median of 7 days for both groups). Note: The effect of ivermectin on viral load was not evaluated and the impact of confounding factors in these patients (e.g., time from diagnosis to initiation of treatment, differences in drugs used for standard care and variances in clinical benefits of such drugs) is not known.</td>
<td>Several clinical trials evaluating ivermectin for the treatment of COVID-19 are registered at clinicaltrials.gov.</td>

<td>Nebulized drugs</td>
<td></td>
<td><strong>Potential harm:</strong> Concern that use of nebulized drugs (e.g., albuterol) for the management of respiratory conditions in patients with COVID-19 infection may distribute the virus into the air and expose close contacts.(^1,2,4,5)</td>
<td>Nebulizer treatment used in clinical practice to treat influenza and other respiratory infections is thought to generate droplets or aerosols. In one study, nebulized saline delivered droplets in the small-medium-size aerosol/droplet range. These results may have infection control implications for airborne infections, including severe acute respiratory syndrome and pandemic influenza infection.(^3)</td>
<td></td>
<td>American College of Allergy, Asthma &amp; Immunology (ACAAI) recommends that nebulized albuterol should be administered in a location that minimizes exposure to close contacts who do not have COVID-19 infection. In the home, choose a location where air is not recirculated (e.g., porch, patio, or garage) or areas where surfaces can be cleaned easily or may not need cleaning.(^2,4) In hospitals, clinicians typically use nebulizers to deliver medications such as albuterol, but are being encouraged to switch to use of metered-dose or dry powder inhalers in patients who are awake and who can perform specific breathing techniques because of the risk of the virus becoming airborne when treating patients infected with COVID-19.(^2,5) There is a lack of published information and guidance on the optimal administration of aerosolized drugs in the treatment of patients with COVID-19. The safe and effective delivery of aerosol therapy to such patients may require modifications in dosage, frequency, and delivery techniques.(^5) WHO states there is insufficient evidence to classify nebulizer therapy as an aerosol-generating procedure associated with COVID-19 transmission and that further study is needed.(^6)</td>

| Nonsteroidal Anti-inflammatory Agents (NSAIAs) | 28:08.04 Nonsteroidal Anti-inflammatory Agent (NSAIA) | **Ibuprofen**: Speculative link between ibuprofen and increased ACE2 expression, which possibly could lead to worse outcomes in COVID-19 patients 1  
**Indomethacin**: In vitro antiviral activity in SARS-CoV-2 pseudovirus-infected Vero E6 cells; also has in vitro activity against other coronaviruses: SARS-CoV-1 (in Vero E6 and human pulmonary epithelial [A549] cells) and canine coronavirus; also has in vivo activity against canine coronavirus in dogs 6, 7 (interferes with viral RNA synthesis) 8, 9  
**Ibuprofen**: In a national registry-based cohort study in Denmark, NSAIA use was *not* associated with increased 30-day mortality, hospitalization, ICU admission, mechanical ventilation, or renal replacement therapy in individuals who tested positive for SARS-CoV-2. In this study, of the 9236 individuals who had a positive PCR test for SARS-CoV-2, 2.7% had used NSAIAs (defined as individuals having filled a prescription for an NSAIA within 30 days prior to a positive SARS-CoV-2 test) based on national community pharmacy records. The authors note that in Denmark, NSAIAs are available only by prescription with the exception of low-dose ibuprofen (200 mg) sold over the counter (OTC) in packages of no more than 20 tablets, and such OTC purchases of ibuprofen constituted 15% of total ibuprofen sales and a smaller proportion of total NSAIA sales. This definition of NSAIA use was a major limitation of the study 14  
**Ibuprofen**: In a retrospective cohort study of 403 hospitalized patients with COVID-19 at a single center in Israel, use of ibuprofen (1 week prior to diagnosis or during the course of disease) was not associated with increased mortality or the need for respiratory support compared with acetaminophen or no antipyretic drug. 15  
**Indomethacin**: In vitro studies and animal models only; currently no published studies evaluating use specifically in COVID-19 patients | | | | Concerns that anti-inflammatory drugs such as ibuprofen may worsen COVID-19 circulated widely in the early months of the pandemic. 5, 12, 14 These reports were based largely on a letter published in *The Lancet Respir Med* stating that increased expression of ACE2 could facilitate infection with COVID-19 and that ibuprofen can increase ACE2. 5, 12, 14 In addition, there were unconfirmed reports of younger, healthy patients who had used ibuprofen to treat early symptoms of COVID-19 and later experienced severe outcomes. 10, 12, 14  
A statement attributed to the WHO recommending paracetamol and avoiding ibuprofen as a self-medication was widely circulated in the media; however, such a position by the WHO has not been substantiated. WHO subsequently performed a rapid review of the literature and concluded that there was no evidence at that time of severe adverse events or effects on acute health care utilization, long-term survival, or quality of life in patients with COVID-19 as a result of the use of NSAIAs. 9  
FDA has stated that it is not aware of scientific evidence connecting the use of NSAIAs, such as ibuprofen, with worsening COVID-19 symptoms and will communicate publicly when more information is available. FDA also noted that all prescription NSAIA labels warn that ibuprofen, with worsening COVID-19 symptoms and will communicate publicly when more information is available. FDA also noted that all prescription NSAIA labels warn that ibuprofen can increase ACE2. 5, 12, 14 In addition, there were unconfirmed reports of younger, healthy patients who had used ibuprofen to treat early symptoms of COVID-19 and later experienced severe outcomes. 10, 12, 14  
Although there currently is no compelling evidence to support an association between ibuprofen and negative outcomes in patients with COVID-19, some experts have recommended... |

<tr>
<td>Tissue Plasminogen Activator (t-PA; alteplase)</td>
<td>20:12.20 Thrombolytic agents</td>
<td>A consistent finding in patients with severe COVID-19 is a hypercoagulable state, which has been shown to contribute to poor outcomes (e.g., progressive respiratory failure, acute respiratory distress syndrome [ARDS], death).</td>
<td>Results of a small phase 1 study suggested possible benefit of plasminogen activators in the treatment of ARDS. In this study, 20 patients with ARDS secondary to trauma and/or sepsis who failed to respond to standard ventilator therapy and were not expected to survive were treated with urokinase or streptokinase; such therapy improved PaO&lt;sub&gt;2&lt;/sub&gt; and also appeared to improve survival. In a case series of 5 COVID-19 patients who had severe hypoxemia, declining respiratory status, and increasing oxygen requirements, administration of t-PA (alteplase) at an initial IV bolus dose of 25 mg over 2 hours followed by a continuous IV infusion of 25 mg over the next 22 hours appeared to improve oxygen requirements in all patients and prevent progression to mechanical ventilation in 3 of the patients. Other case series have described the use of t-PA in COVID-19 patients with severe respiratory failure or ARDS who were rapidly deteriorating.</td>
<td>Two dosage regimens of t-PA (alteplase) are being evaluated in the open-label systemic fibrinolytic therapy trial (NCT04357730): 50 mg (administered as a 10-mg IV bolus followed by IV infusion of the remaining 40 mg over a total time of 2 hours) and 100 mg (administered as a 10-mg IV bolus dose followed by IV administration of the remaining 90 mg over a total time of 2 hours); a heparin infusion will be initiated immediately following completion of the alteplase infusion. Other dosage regimens have been evaluated in patients with COVID-19, including an initial t-PA (alteplase) dose of 25 mg administered IV over 2 hours, followed by an IV infusion of 25 mg of t-PA over the subsequent 22 hours, with a dose not to exceed 0.9 mg/kg; however, the optimum dose, route of administration, and duration of treatment remain to be determined.</td>
<td>NIH COVID-19 Treatment Guidelines Panel states that patients who are receiving NSAIDs for other conditions should continue receiving the drugs; the panel also states that antipyretic strategy (e.g., use of acetaminophen or NSAIDs) should be no different between patients with or without COVID-19. The Surviving Sepsis Campaign COVID-19 guidelines state that until more evidence is available, use of acetaminophen over no treatment for fever control is suggested (weak recommendation). IDSA makes no specific recommendation for or against the use of NSAIDs in patients with COVID-19. Indomethacin: Additional data needed to determine whether in vitro activity against SARS-CoV-2 corresponds with clinical efficacy in the treatment of COVID-19.</td>
